***Via Electronic Filing***

Kimberly D. Bose, Secretary
Federal Energy Regulatory Commission
888 First Street, NE
Washington, DC 20426

**Subject:** **Ripogenus Hydroelectric Project (FERC No. 2572)**
**Penobscot Mills Hydroelectric Project (FERC No. 2458)**
**Notices of Intent to File License Application**
**and Pre-Application Document**

Dear Secretary Bose:

Great Lakes Hydro America, LLC (GLHA), a subsidiary of Brookfield Renewable and Licensee of the Ripogenus Hydroelectric Project (FERC No. 2572) and Penobscot Mills Hydroelectric Project (FERC No. 2458) (collectively referred to as the "Projects"), herein files with the Federal Energy Regulatory Commission (FERC or Commission) Notices of Intent (NOIs) and a Pre-Application Document (PAD) for the relicensing of the Projects. The Projects are located on the West Branch of the Penobscot River and Millinocket Stream in Piscataquis and Penobscot Counties, Maine.

Each Project's current FERC license was issued on October 22, 1996 and expires on September 30, 2026. Accordingly, GLHA is pursuing two separate new licenses for the continued operation of the Projects through the Commission's Integrated Licensing Process (ILP).

The enclosed PAD consists of two volumes. Volume I of the PAD contains public information, and Volume II of the PAD contains single-line diagrams and detailed drawings of Project works, which are considered Controlled Unclassified Information (CUI)/Critical Energy Infrastructure Information (CEII). Pursuant to 18 Code of Federal Regulations (CFR) §388.113, GLHA requests that the Commission consider this non-public information.

Concurrent with this filing and in accordance with 18 CFR §5.5(c), GLHA is providing a copy of this letter to all parties listed in the attached distribution list. Parties with interest in the upcoming relicensing can download an electronic copy of the NOIs and PAD from FERC's eLibrary system at https://www.ferc.gov/docs-filing/elibrary.asp by conducting a search using the docket numbers p-2458 and/or p-2572. In accordance with 18 CFR §5.2, a copy of the NOIs and PAD is also available for review by appointment at GLHA's offices at 1024 Central Street, Millinocket, ME 04462. Given the restrictions associated with the ongoing COVID-19 pandemic, GLHA is

Great Lakes Hydro America, LLC
1024 Central Street
Millinocket, ME 04462

Tel: 207.723.4341
Fax: 207.723.3948

not providing paper copies of the NOIs or PAD to Commission Staff in the Office of Energy Projects or Office of General Counsel – Energy Projects.

In accordance with 18 CFR 5.5(e), GLHA is requesting designation as the Commission's non-federal representative for the purpose of consultation under Section 7 of the Endangered Species Act and the joint agency regulations thereunder at 50 CFR 402. GLHA also requests that FERC authorize GLHA to initiate consultation under Section 106 of the National Historic Preservation Act and the implementing regulations at 36 CFR 800.2(c)(4).

If you have any questions regarding the NOIs or PAD, please contact me by phone at (207) 775-5605 or by email at randy.dorman@brookfieldrenewable.com.

Sincerely,

Randall Dorman
Licensing Manager
Brookfield Renewable

CAUTION: [EXTERNAL] This email originated from outside of the organization. Do not click links or open attachments unless you recognize the sender and know the content is safe.

Good morning,

We do not have an immediate concern with your project or project site, and do not currently have the resources to fully investigate same. Should any human remains, archaeological properties or other items of historical importance be unearthed while working on this project, we recommend that you stop your project and report your findings to the appropriate authorities including the Houlton Band of Maliseet Indians.

Thank you,

Isaac St. John

**Subject:** Ripogenus & Penobscot Mills Hydroelectric Projects: Notices of Intent to File License Application and Pre-Application Document

Dear Stakeholders –

The Ripogenus Hydroelectric Project (FERC No. 2572) and the Penobscot Mills Hydroelectric Project (FERC No. 2458), located on the West Branch of the Penobscot River in Piscataquis and Penobscot Counties, Maine, are currently licensed with the Federal Energy Regulatory Commission (FERC). The licensee, Great Lakes Hydro America, LLC (GLHA), a subsidiary of Brookfield Renewable, has begun the federal relicensing process by filing Notices of Intent to File License Application (NOIs) and a Pre-Application Document (PAD) for these facilities.

On behalf of GLHA, attached is the transmittal for these documents, which provides instructions as to how to obtain a copy of the NOIs and PAD from FERC's eLibrary system at https://elibrary.ferc.gov/idmws/search/fercgensearch.asp.

Given that our contact database includes your email address, we are providing a copy of this letter via email, in lieu of a direct mailing. If you would like to receive paper copies of future letters, as compared to emails, please contact Cate Russell with HDR at cate.russell@hdrinc.com or (207) 239-3792.

If there are any questions regarding this email, the attachment, or the NOIs/PAD please contact Randall Dorman with Brookfield Renewable at (207) 755-5605 or Randy.Dorman@hdrinc.com or Jim Gibson with HDR at (315) 414-2202 or Jim.Gibson@hdrinc.com.

Sincerely,

**Cate Russell**

Portland, ME 04103

Project: MHPC #1049-21 Great Lakes Hydroelectric; Ripogenus FERC 2572; Penobscot Mills FERC 2458
NOI License Application

Town: Various, ME

Dear Ms. Russell:

In response to your recent request, I have reviewed the information received June 14, 2021 to initiate consultation on the above referenced project in accordance with Section 106 of the National Historic Preservation Act of 1966, as amended.

The area of potential effect as noted on page 5-252 is "defined as all lands and waters within the Project Boundary.... This includes the area where Project operations or Project-related recreation activities or other enhancements may cause changes in the character or use of historic properties." Based on this definition of the APE, it is unclear from the discussion in Section 5.10.2 as to whether the entire Project Boundary was surveyed for architectural resources during the prior re-licensing effort. If such a survey was not conducted, or if it needs to be updated to identify other properties that are now 50 years of age or older, the Commission recommends that the applicant undertake further studies to identify all properties in the APE that may be eligible for listing in the National Register of Historic Places.

An architectural survey is recommended to identify and record information on all resources within the area of potential effect (APE) that are at least 50 years old. Survey must be completed according to our "Revised Above Ground Cultural Resource Survey Manual Project Review Specific." All surveys must be submitted electronically via our on-line CARMA database. See our website for more information: https://www.maine.gov/mhpc/quick-links/forms-instructions

A list of historic preservation consultants who are qualified to conduct architectural survey and have been trained in the use of the CARMA database may be found at the following page of our website: https://www.maine.gov/mhpc/programs/survey/approved-consultants/carma-trained-consultants

The archaeological resources section of the PAD (pp. 5-254 through 5-268 for Ripogenus and 5-265 through 5-268 for Penobscot Mills) accurately summarized archaeological mitigation work to date on the sites listed in the HPMP for the October 1996 license. No further Phase I or Phase II archaeological survey is necessary. Mitigation archaeological work not yet completed for the 1996 license should be brought forward for an HPMP for the 2026 license. Continued analysis and reporting on excavated sites (e.g. p5-261 and 5/262) should be a priority. Attempts to access the sites that have been difficult to access because of water levels or landowner permissions should continue.

After the 1996 license, a major archaeological collection (the Dan Hurld collection) primarily from the Penobscot Mills project area was acquired by the Maine State Museum. This collection consists of over 1000

stone tools and several hundred pieces of Native American ceramics, recovered during periods of low water on the Penobscot Mills lakes by Dan Hurld between about 1930 and 1955. The artifacts are marked by site location and can be attributed to specific archaeological sites by site number. This collection will provide a major increase in cultural context (age of occupation, types of artifacts at each site) when combined with existing information from the Phase I, II and mitigation work. We request that a professional analysis of the Dan Hurld collection, and integration of the information contained within it to the known site information be undertaken and funded as part of the HPMP for the 2026 license, or as work in advance of license issuance. This is appropriate mitigation for the effects of the raised water levels on the Penobscot Mills impoundments on scores of archaeological sites around the impoundment.

If you have any questions regarding archaeology, please contact Dr. Arthur Spiess of this office at Arthur.Spiess@maine.gov.

Please contact Megan M. Rideout of our staff at 287-2992 or megan.m.rideout@maine.gov if you have any questions regarding above ground resources.

Sincerely,

Kirk F. Mohney

**Project:** Penobscot Mills Hydroelectric Project

**Subject: Consultation with Tribes for the Penobscot Mills Hydroelectric Project No. 2458-247**

On April 15, 2021, Dustin Wilson, staff of the Division of Hydropower Licensing with the Federal Energy Regulatory Commission (Commission) issued a letter initiating Tribal consultation for the licensing process for the Penobscot Mills Hydroelectric Project No. 2458 (Penobscot Mills Project). Mr. Wilson followed up with the addressed Tribes via telephone on June 10, 2021, June 16, 2021, and June 28, 2021 to determine if any would be interested in participating in consultation for the Penobscot Mills Project. Mr. Wilson followed up with Donald Soctomah of the Passamquoddy Tribe on July 8, 2021 and he stated potential concerns associated with any construction. John Dennis of the Aroostook Band of Micmacs stated on June 28, 2021 that there were no concerns. No responses were received from the Houlton Band of Maliseet or the Penobscot Indian Nation.

2458-247

# NOTICE OF INTENT TO FILE LICENSE APPLICATIONS, FILING OF PRE-APPLICATION DOCUMENT, COMMENCEMENT OF PRE-FILING PROCESS, AND SCOPING; REQUEST FOR COMMENTS ON THE PAD AND SCOPING DOCUMENT, IDENTIFICATION OF ISSUES AND ASSOCIATED STUDY REQUESTS, AND VIRTUAL PUBLIC SCOPING MEETINGS AND VIRTUAL ENVIRONMENTAL SITE REVIEW

(August 10, 2021)

a. Type of Filing: Notices of Intent to File License Applications for New License and Commencing Pre-filing Process

b. Project Nos.: 2572-133 and 2458-247

c. Date Filed: June 11, 2021

d. Submitted By: Great Lakes Hydro America, LLC

e. Name of Projects: Ripogenus Hydroelectric Project and Penobscot Mills Hydroelectric Project

f. Location: On the West Branch of the Penobscot River and Millinocket Stream in Piscataquis and Penobscot Counties, Maine.

g. Filed Pursuant to: 18 CFR Part 5 of the Commission's Regulations.

h. Licensee Contact: Randall Dorman, Licensing Manager, Brookfield Renewable, 150 Main Street, Lewiston, ME 04240; (207) 755-5605; randy.dorman@brookfieldrenewable.com.

i. FERC Contact: Allan Creamer at (202) 502-8365, or e-mail at allan.creamer@ferc.gov.

j. Cooperating agencies: Federal, state, local, and tribal agencies with jurisdiction and/or special expertise with respect to environmental issues that wish to cooperate in the preparation of the environmental document should

follow the instructions for filing such requests described in item o below. Cooperating agencies should note the Commission's policy that agencies that cooperate in the preparation of the environmental document cannot also intervene. *See* 94 FERC 61,076 (2001).

k. With this notice, we are initiating informal consultation with: (a) the U.S. Fish and Wildlife Service and/or NOAA Fisheries under section 7 of the Endangered Species Act and the joint agency regulations thereunder at 50 CFR, Part 402; and (b) the State Historic Preservation Officer, as required by section 106, National Historic Preservation Act, and the implementing regulations of the Advisory Council on Historic Preservation at 36 CFR 800.2.

l. With this notice, we are designating Great Lakes Hydro America, LLC as the Commission's non-federal representative for carrying out informal consultation, pursuant to section 7 of the Endangered Species Act and section 106 of the National Historic Preservation Act.

m. Great Lakes Hydro America, LLC filed with the Commission a Pre-Application Document (PAD; including a proposed process plan and schedule), pursuant to 18 CFR 5.6 of the Commission's regulations.

n. In addition to publishing the full text of this document in the Federal Register, the Commission provides all interested persons an opportunity to view and/or print the contents via the Internet through the Commission's Home Page (http://www.ferc.gov), using the "eLibrary" link. Enter the docket number(s), excluding the last three digits in the docket number field, to access the document. At this time, the Commission has suspended access to the Commission's Public Reference Room, due to the proclamation declaring a National Emergency concerning the Novel Coronavirus Disease (COVID-19), issued by the President on March 13, 2020. For assistance, contact FERC Online Support at Mailto:FERCOnlineSupport@ferc.gov, or call toll-free, (866) 208-3676 or TYY, (202) 502-8659.

Register online at http://www.ferc.gov/docs-filing/esubscription.asp to be notified via e-mail of new filings and issuances related to these or other pending projects. For assistance, contact FERC Online Support.

o. With this notice, we are soliciting comments on the PAD and Commission staff's Scoping Document 1 (SD1), as well as study requests. All comments on the PAD and SD1, and study requests should be sent to the address above in paragraph h. In addition, all comments on the PAD and SD1, study requests, requests for cooperating agency status, and all communications to and from

Commission staff related to the merits of the potential applications must be filed with the Commission.

The Commission strongly encourages electronic filing. Please file all documents using the Commission's eFiling system at http://www/ferc.gov/docs-filing/efiling.asp. Commenters can submit brief comments up to 6,000 characters, without prior registration, using the eComment system at http://www.ferc.gov/docs-filing/ecomment.asp. You must include your name and contact information at the end of your comments. For assistance, please contact FERC Online Support at Mailto:FERCOnlineSupport@ferc.gov. In lieu of electronic filing, you may submit a paper copy. Submissions sent via the U.S. Postal Service must be addressed to: Kimberly D. Bose, Secretary, Federal Energy Regulatory Commission, 888 First Street NE, Room 1A, Washington, DC 20426. Submissions sent via any other carrier must be addressed to: Kimberly D. Bose, Secretary, Federal Energy Regulatory Commission, 12225 Wilkins Avenue, Rockville, Maryland 20852.

All filings with the Commission must bear the appropriate heading: "Comments on Pre-Application Document," "Study Requests," "Comments on Scoping Document 1," "Request for Cooperating Agency Status," or "Communications to and from Commission Staff." Any individual or entity interested in submitting study requests, commenting on the PAD or SD1, and any agency requesting cooperating status must do so by **October 9, 2021**.

p. Scoping Process

The Commission's scoping process will help determine the required level of analysis and satisfy the NEPA scoping requirements, irrespective of whether the Commission prepares an environmental assessment or Environmental Impact Statement. Due to on-going concerns with large gatherings related to COVID-19, we do not intend to hold in-person public scoping meetings or an in-person environmental site review. Rather, we will hold virtual public scoping meetings and a virtual environmental site review

Scoping Meetings

Commission staff will hold two virtual public scoping meetings. A daytime meeting will focus on concerns of resource agencies, Native American tribes, and NGOs while an evening meeting will focus on receiving input from the public. We invite all interested agencies, Native American tribes, NGOs, and individuals to attend one of these meetings to assist us in identifying the scope of environmental issues that should be analyzed in the NEPA document. The

scoping meetings will be recorded by a court reporter. All oral and written comments will become part of the Commission's public record. Oral comments will be limited to 5 minutes in duration.

| **Date and Time** |
|---|
| Meeting for resource agencies, Tribes, and NGOs<br>Thursday, September 9, 2021<br>9:00 -11:00 am EDT<br>Call in number: 888-604-9359<br>Participant passcode: 8998724 |
| Meeting for the general public<br>Thursday, September 9, 2021<br>6:30 - 8:30 pm EDT<br>Call in number: 888-604-9359<br>Participant passcode: 8998724 |

Scoping Document 1 (SD1), which outlines the subject areas to be addressed in the environmental document, was mailed to the individuals and entities on the Commission's mailing list and Great Lakes Hydro America, LLC's mailing list. Copies of SD1 may be viewed on the web at http://www.ferc.gov, using the "eLibrary" link. Follow the directions for accessing information in paragraph n. Based on all oral and written comments, a Scoping Document 2 (SD2) may be issued. SD2 may include a revised process plan and schedule, as well as a list of issues, identified through the scoping process.

Environmental Site Review

Great Lakes Hydro America, LLC and Commission staff will hold a virtual Environmental Site Review of the Ripogenus Project and the Penobscot Mills Projects on September 9, 2021, starting at 1:30 p.m. Please contact Cate Russell of HDR, Inc. at (207) 239-3792, or cate.russell@hdrinc.com, by September 3, 2021, if you plan to attend the environmental site review. WebEx meeting details will be provided by HDR staff once attendance is confirmed.

Meeting Objectives

At the scoping meetings, staff will: (1) briefly describe the relicensing process, as well as the projects and their operation; (2) initiate scoping of the issues; (3) review existing information and identify preliminary information and study needs; and (4) review the process plan and schedule for pre-filing activities. Meeting participants should come prepared to discuss their issues and/or concerns. Please review the PAD in preparation for the scoping meetings. Directions on how to obtain a copy of the PAD and SD1 are included in item n of this notice.

Kimberly D. Bose,
Secretary.

FEDERAL ENERGY REGULATORY COMMISSION
Washington, DC 20426
August 10, 2021

OFFICE OF ENERGY PROJECTS

Project Nos. 2572-133 & 2458-247 –
Maine
Ripogenus Hydroelectric Project
Penobscot Mills Hydroelectric Project
Great Lakes Hydro America, LLC

**VIA FERC Service**

**Reference: Scoping Document 1 for the Ripogenus Hydroelectric Project (P-2572-133) and Penobscot Mills Hydroelectric Project (P-2458-247)**

To the Parties Addressed:

The Federal Energy Regulatory Commission (Commission) is currently reviewing the Pre-Application Document (PAD) submitted by Great Lakes Hydro America, LLC (GLHA), a subsidiary of Brookfield Renewable, for relicensing the Ripogenus Hydroelectric Project (FERC No. 2572) and the Penobscot Mills Hydroelectric Project (FERC No. 2458) (collectively referred to as the "Projects"). The Projects are located on the West Branch of the Penobscot River and Millinocket Stream in Piscataquis and Penobscot Counties, Maine. The Projects do not occupy any federal land.

Pursuant to the National Environmental Policy Act (NEPA) of 1969, as amended, Commission staff will prepare an environmental document (NEPA document) which will be used by the Commission to determine whether, and under what conditions, to issue a new license for the Projects. To support and assist our environmental review and determine the level of analysis needed, we are beginning the public scoping process to ensure that all pertinent issues are identified and analyzed, and that the NEPA document is thorough and balanced.

We invite your participation in the scoping process and are circulating the attached Scoping Document 1 (SD1) to provide you with information on the Projects. We are also soliciting your comments and suggestions on our preliminary list of issues and alternatives to be addressed in the NEPA document. We are requesting that you identify

any studies that would help provide a framework for collecting pertinent information on the resource areas under consideration necessary for the Commission to prepare the NEPA document for the Projects.

Due to concerns with large gatherings related to COVID-19, we do not intend to conduct in-person public scoping meetings or an in-person environmental site review. We are soliciting electronic or written comments, recommendations, and information on SD1. In lieu of sending written comments, the Commission invites you to attend one of the virtual scoping meetings its staff will conduct by telephone (*see* section 2.2, *Comments, Scoping Meetings, and Environmental Site Review* of the attached SD1).

SD1 is being distributed to GLHA's distribution list and the Commission's official mailing list (*see* section 9.0, *Mailing Lists*, of the attached SD1). If you wish to be added to, or removed from, the Commission's official mailing list, please send your request by email to Mailto:FERCOnlineSupport@ferc.gov. In lieu of an email request, you may submit a paper request. Submissions sent via the U.S. Postal Service must be addressed to: Kimberly D. Bose, Secretary, Federal Energy Regulatory Commission, 888 First Street NE, Room 1A, Washington, DC 20426. Submissions sent via any other carrier must be addressed to: Kimberly D. Bose, Secretary, Federal Energy Regulatory Commission, 12225 Wilkins Avenue, Rockville, Maryland 20852. All written or emailed requests must specify your wish to be added to, or removed from, the mailing list for the Projects, and must clearly identify **Ripogenus Hydroelectric Project (P-2572-133)** and/or **Penobscot Mills Hydroelectric Project (P-2458-247)** on the first page.

Please review SD1 and, if you wish to provide comments, follow the instructions in section 6.0, *Request for Information and Studies*. If you have any questions about SD1, the scoping process, or how Commission staff will develop the NEPA document for the Projects, please contact Allan Creamer at (202) 502-8365, or at allan.creamer@ferc.gov. Additional information about the Commission's licensing process and the project may be obtained from the Commission's website, www.ferc.gov. The deadline for filing comments is **October 9, 2021**. The Commission strongly encourages electronic filings.

# SCOPING DOCUMENT 1

## Ripogenus Hydroelectric Project (FERC No. 2572-133)
## Penobscot Mills Hydroelectric Project (FERC No. 2458-247)

## 1.0 INTRODUCTION

The Federal Energy Regulatory Commission (Commission or FERC), under the authority of the Federal Power Act (FPA),[1] may issue licenses for terms ranging from 30 to 50 years for the construction, operation, and maintenance of non-federal hydroelectric projects. On June 11, 2021, Great Lakes Hydro America, LLC (GLHA), filed notices of intent and a pre-application document (NOI/PAD) for new licenses for the Ripogenus Hydroelectric Project No. 2572-133 (Ripogenus Project) and the Penobscot Mills Hydroelectric Project No. 2458-247 (Penobscot Mills Project) (collectively, the "Projects"). The Projects are located on the West Branch of the Penobscot River and Millinocket Stream in Piscataquis and Penobscot Counties, Maine (figure 1). A detailed description of the Projects is provided in section 3.0, *Proposed Actions and Alternatives*. The Projects do not occupy federal lands.

The National Environmental Policy Act (NEPA) of 1969,[2] the Commission's regulations, and other applicable laws require that we independently evaluate the environmental effects of relicensing the Projects as proposed, and consider reasonable alternatives to the proposed actions.[3] We will prepare an environmental document (NEPA document) that describes and evaluates the probable effects, if any, of the licensee's proposed actions for the Projects and alternatives to the proposed actions. The Commission's scoping process will help determine the required level of analysis and satisfy the NEPA scoping requirements, irrespective of whether the Commission issues an environmental analysis (EA) or an environmental impact statement (EIS).

[1] 16 U.S.C. § 791(a)-825(r).

[2] 42 U.S.C. §§ 4321-4370(f).

[3] The Council on Environmental Quality (CEQ) issued a final rule on July 15, 2020, revising the regulations under 40 C.F.R. Parts 1500 – 1518 that federal agencies use to implement NEPA (*see* Update to the Regulations Implementing the Procedural Provisions of the National Environmental Policy Act, 85 Fed. Reg. 43,304). The Final Rule became effective on, and applies to any NEPA process begun after, September 14, 2020. Commission staff intends to conduct its NEPA review in accordance with CEQ's new regulations.

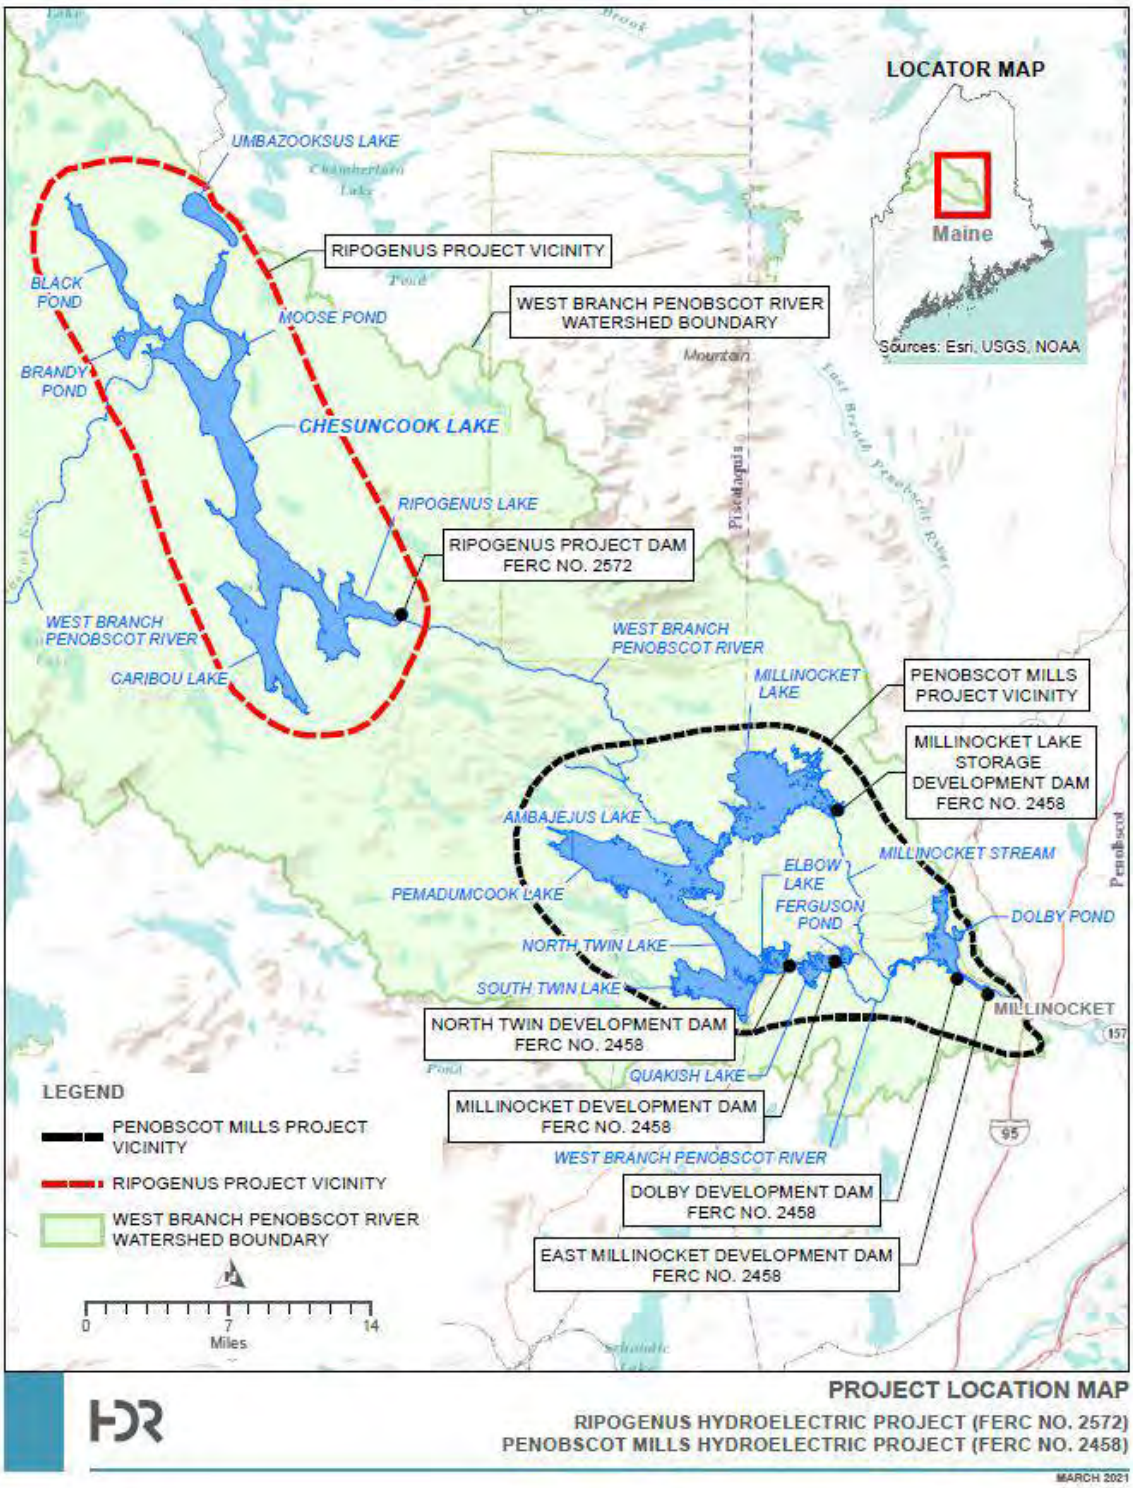

Figure 1. Location of the Ripogenus and Penobscot Mills Hydroelectric Projects (source: PAD).

# 2.0 SCOPING

This Scoping Document 1 (SD1) is intended to advise all participants as to the proposed scope of the NEPA document and to seek additional information pertinent to this analysis. This document contains: (1) a description of the scoping process and the development of the license applications; (2) a description of the licensee's proposed actions and alternatives to the proposed actions for the Projects; (3) a preliminary identification of environmental issues for the Projects; and (4) a preliminary list of comprehensive plans that are applicable to the Projects.

## 2.1 PURPOSES OF SCOPING

Scoping is the process used to identify issues, concerns, and opportunities for enhancement or mitigation associated with a proposed action. According to NEPA, the process should be conducted early in the planning stage of the project. The purposes of the scoping process are as follows:

- invite participation of federal, state and local resource agencies, Native-American tribes, non-governmental organizations (NGOs), and the public to identify significant environmental and socioeconomic issues related to the proposed Projects;

- determine the resource issues, depth of analysis, and significance of issues to be addressed in the NEPA document;

- identify reasonable alternatives to the proposed actions for the Projects that should be evaluated in the NEPA document;

- solicit available information on the resources at issue and study needs; and

- determine the resource areas and potential issues that do not require detailed analysis during review of the Projects.

## 2.2 COMMENTS, SCOPING MEETINGS, AND ENVIRONMENTAL SITE REVIEW

During preparation of the NEPA document, there will be several opportunities for the resource agencies, Native-American tribes, NGOs, and the public to provide input.

These opportunities occur:

- during the public scoping process and study plan meetings, when we solicit comments regarding the scope of issues and analysis for the NEPA document;

- in response to the Commission's notice that the Projects are ready for environmental analysis; and

- after issuance of the NEPA document when we solicit comments on the document.

Due to on-going concerns with large gatherings related to COVID-19, we do not intend to hold in-person public scoping meetings or an in-person environmental site review. We are soliciting written comments and recommendations on the preliminary list of issues and alternatives to be addressed in the NEPA document. In addition to written comments solicited by this SD1, we will hold two virtual public scoping meetings and a virtual environmental site review. A daytime meeting will focus on concerns of resource agencies, Native-American tribes, and NGOs while an evening meeting will focus on receiving input from the public. We invite all interested agencies, Native-American tribes, NGOs, and individuals to attend one of these meetings to assist us in identifying the scope of environmental issues that should be analyzed in the NEPA document. We also invite all stakeholders to attend the virtual environmental site review. Please contact Cate Russell of HDR, Inc. at (207) 239-3792, or cate.russell@hdrinc.com, by September 3, 2021, if you plan to attend the environmental site review.

The virtual scoping meetings and virtual environmental site review are scheduled as follows:

| **Date and Time** |
|---|
| Meeting for resource agencies, Tribes, and NGOs<br>Thursday, September 9, 2021<br>9:00 -11:00 am EDT<br>Call in number: 888-604-9359<br>Participant passcode: 8998724 |
| Environmental Site Review for all stakeholders<br>Thursday, September 9, 2021<br>1:30 – 3:30 pm EDT<br>WebEx meeting details provided by HDR staff |

| Date and Time |
| --- |
| Meeting for the general public<br>Thursday, September 9, 2021<br>6:30 - 8:30 pm EDT<br>Call in number: 888-604-9359<br>Participant passcode: 8998724 |

The scoping meetings will be recorded by a court reporter. All oral and written comments will become part of the Commission's public record. Oral comments will be limited to 5 minutes in duration. Interested stakeholders who choose not to speak or who are unable to attend the scoping meetings may provide written comments and information to the Commission as described in section 6.0, *Request for Information and Studies*. These meetings are posted on the Commission's calendar located on the internet at http://www.ferc.gov/EventCalendar/EventsList.aspx?View=monthview, along with other related information.

Scoping commenters should provide information on issues and/or concerns as they pertain to the proposed continued operation and maintenance of the Projects. It is advised that commenters review the PAD when preparing comments. Copies of the PAD may be viewed on the Commission's website (http://www.ferc.gov), using the "eLibrary" link. Enter docket numbers, P-2572 for the Ripogenus Project or P-2458 for the Penobscot Mills Project, to access the document. For assistance, contact FERC Online Support at Mailto:FERCOnlineSupport@ferc.gov, or toll free at 1-866-208-3676, or for TTY, (202) 502-8659. At this time, the Commission has suspended access to the Commission's Public Reference Room, due to the proclamation declaring a National Emergency concerning COVID-19 issued by the President on March 13, 2020.

Following the scoping comment period, all issues raised will be reviewed and decisions made as to the level of analysis needed. If this preliminary analysis indicates that any issues presented in this scoping document have little potential for causing significant effects, the issue(s) will be identified and the reasons for not providing a more detailed analysis will be given in the NEPA document.

Commission staff will revise this Scoping Document, as necessary, to reflect the comments received during the comment period. If we receive no substantive comments on SD1, then we will not prepare a Scoping Document 2 (SD2). Otherwise, we will issue SD2 to address any substantive comments received. The NEPA document will address recommendations and input received during the scoping process.

# 3.0 PROPOSED ACTIONS AND ALTERNATIVES

In accordance with NEPA, the environmental analysis will consider the following alternatives, at a minimum: (1) the no-action alternative; (2) the applicant's proposed actions; and (3) alternatives to the proposed actions.

## 3.1 NO-ACTION ALTERNATIVE

Under the no-action alternative, the Ripogenus Project and Penobscot Mills Project would continue to operate as required by their current project licenses (i.e., there would be no change to the existing environment). No new environmental protection, mitigation, or enhancement measures would be implemented. We use this alternative to establish baseline environmental conditions for comparison with other alternatives.

### 3.1.1 Project Facilities

*RIPOGENUS PROJECT*

The Ripogenus Project is located about 21 river miles (RM) upstream of the Penobscot Mills Project on the West Branch of the Penobscot River (West Branch), which flows into Ambajejus Lake (part of the Penobscot Mills Project's North Twin Development). The project generally consists of a dam, reservoir, intake structure, a tunnel and penstocks, powerhouse with generation equipment, and a transmission line (figure 2).[4]

Ripogenus, Caribou, and Chesuncook Lakes and Black, Brandy, and Moose Ponds constitute the Ripogenus impoundment created by Ripogenus Dam. The impoundment is about 20.8 miles long and has a surface area of approximately 29,270 acres at the normal full pond elevation of 941.59 feet United States Geological Survey (USGS) datum.[5] The impoundment's mean depth is 35.8 feet, and usable storage is about 688,705 acre-feet, with a maximum drawdown of 44 feet (to elevation 897.59 feet).[6] Ripogenus Dam, a

[4] This SD1 provides a summary of the Ripogenus Project and the Penobscot Mills Project facilities. The Ripogenus and Penobscot Mills Projects are described in greater detail in section 4.3, *Existing Project Facilities*, of the PAD.

[5] Unless otherwise noted, all elevations cited in this SD1 are in USGS datum.

[6] The Ripogenus Project also includes Umbazooksus Lake, which is a 1,600-acre former storage impoundment that is located within the project boundary. In 1998, the storage and release operations were discontinued so the current flow regime is run-of-

795-foot-long concrete and earth-filled structure, is located at the outlet of Ripogenus Lake. The dam, which crosses the West Branch in a north-south direction, includes two concrete ogee[7] spillway sections totaling about 480 feet in length, a 37-foot-long intake section, a 178-foot-long gated sluice section, and a 100-foot-long earth section.

Water flows from Ripogenus impoundment through a concrete intake structure, which is protected by trash racks with 2-5/8 inch clear spacing. The intake structure connects to 16-foot-diameter concrete-lined tunnel that is approximately 3,850 feet long and connects to three penstocks that lead to the powerhouse (McKay Station). Flows diverted to the tunnel, penstocks, and powerhouse bypass a 0.75-mile-long river reach (Upper Gorge) of the West Branch. The 130-foot-long by 45-foot-wide powerhouse contains three vertical Francis-type turbines, each connected to a generator. The rated capacity of the three turbines is 38.6 MW, and the rated capacity of the three generators is 37.5 MW. Flow from the powerhouse is conveyed back to the West Branch via a 50-foot-long excavated bedrock tailrace.

The power generated at the Ripogenus Project is transmitted to the electric grid via three transformers and transmission lines that start at the substation at McKay Station and extend about 29.4 miles to GLHA's Millinocket Substation #4 (part of the Penobscot Mills Project). An additional 0.75-mile-long transmission line extends from the McKay Substation to Ripogenus Dam to supply backup power to the gate operators and to Ripogenus Village.

The Ripogenus Project also contains one utility-scale battery energy storage site that is part of a Battery Energy Storage System at the Projects (*see* Battery Energy Storage System description for the Penobscot Mills Project).

river. Umbazooksus Lake, therefore, provides no storage capacity to the Ripogenus Project.

[7] An ogee-shaped spillway contains a controlled weir and is S-shaped in profile.

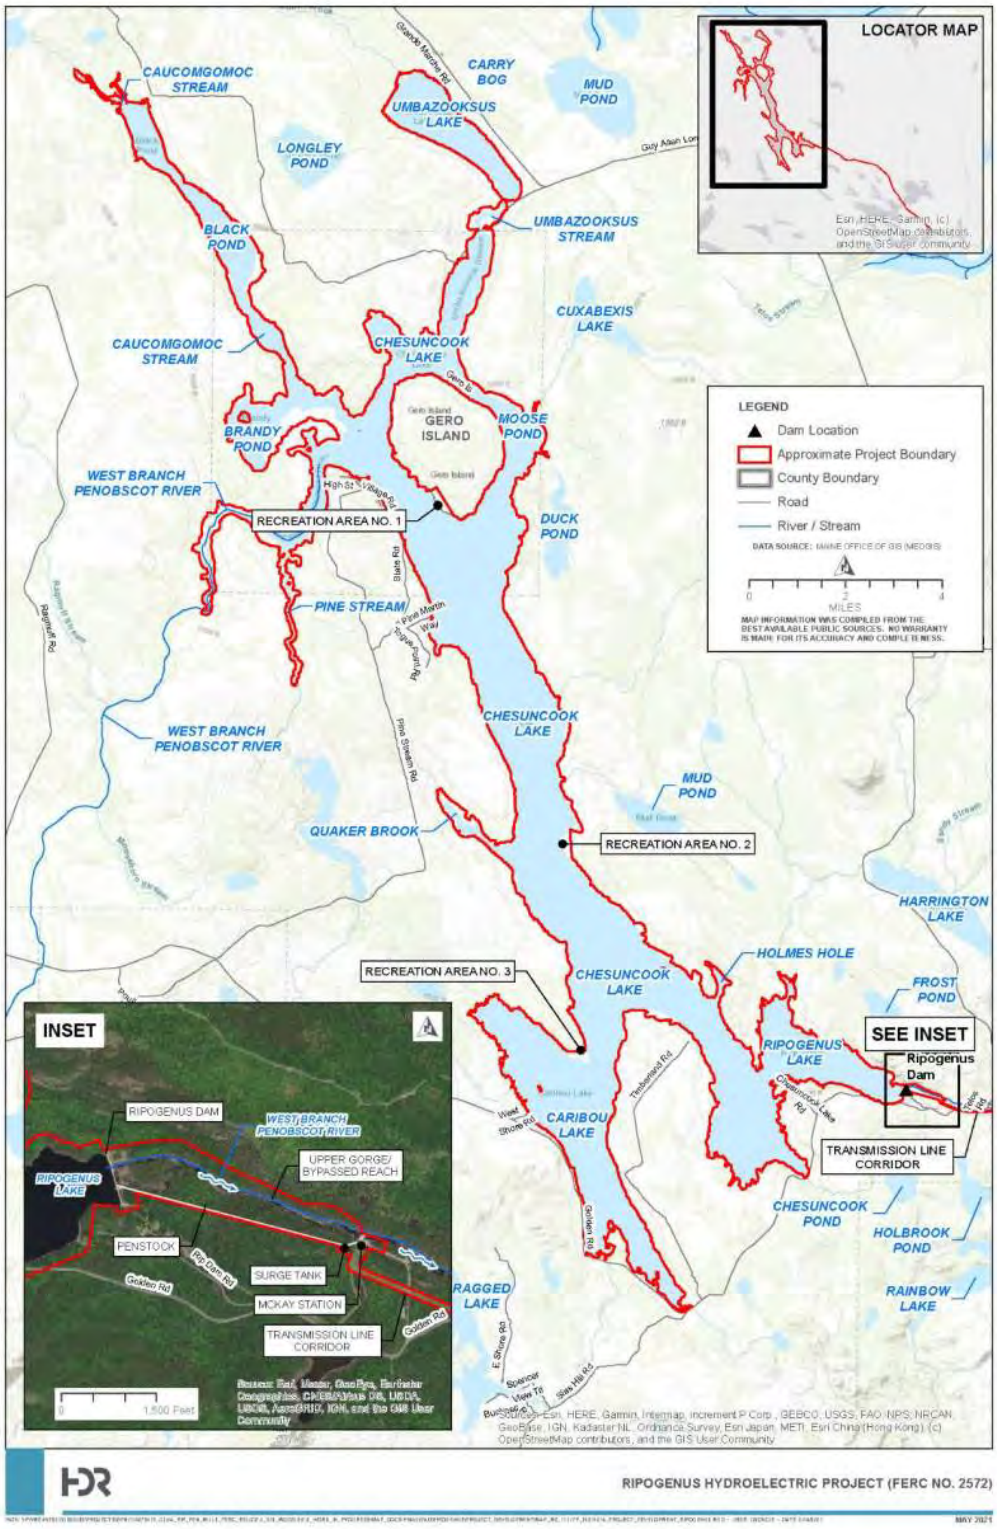

Figure 2. Ripogenus Hydroelectric Project facilities (source: PAD).

*PENOBSCOT MILLS PROJECT*

The Penobscot Mills Project consists of four hydropower developments (North Twin, Millinocket, Dolby, and East Millinocket; located between RM 15 and RM 2 on the West Branch of the Penobscot River) and one storage development (Millinocket Lake Storage Development; located on Millinocket Stream) (figure 3).[8] The primary features of the Penobscot Mills Project include five dams, five impoundments, and four powerhouses. The total installed capacity of the project is 67.9 MW.

The North Twin Impoundment is at the upstream end of the Penobscot Mills Project and receives flow from the Ripogenus Project (figure 3). Releases from the North Twin Development pass through three other developments and associated generation facilities of the Penobscot Mills Project, including the Millinocket, Dolby, and East Millinocket Developments. The Millinocket Lake Storage Development includes a pumping station through which water can be pumped to Ambajejus Lake (within the North Twin impoundment). Otherwise, water is discharged to Millinocket Stream, which enters the West Branch at Shad Pond (downstream from the Millinocket Development; *see* figure 6 below) and passes through the Dolby and East Millinocket Developments.

[8] *See* n. 4 *supra*.

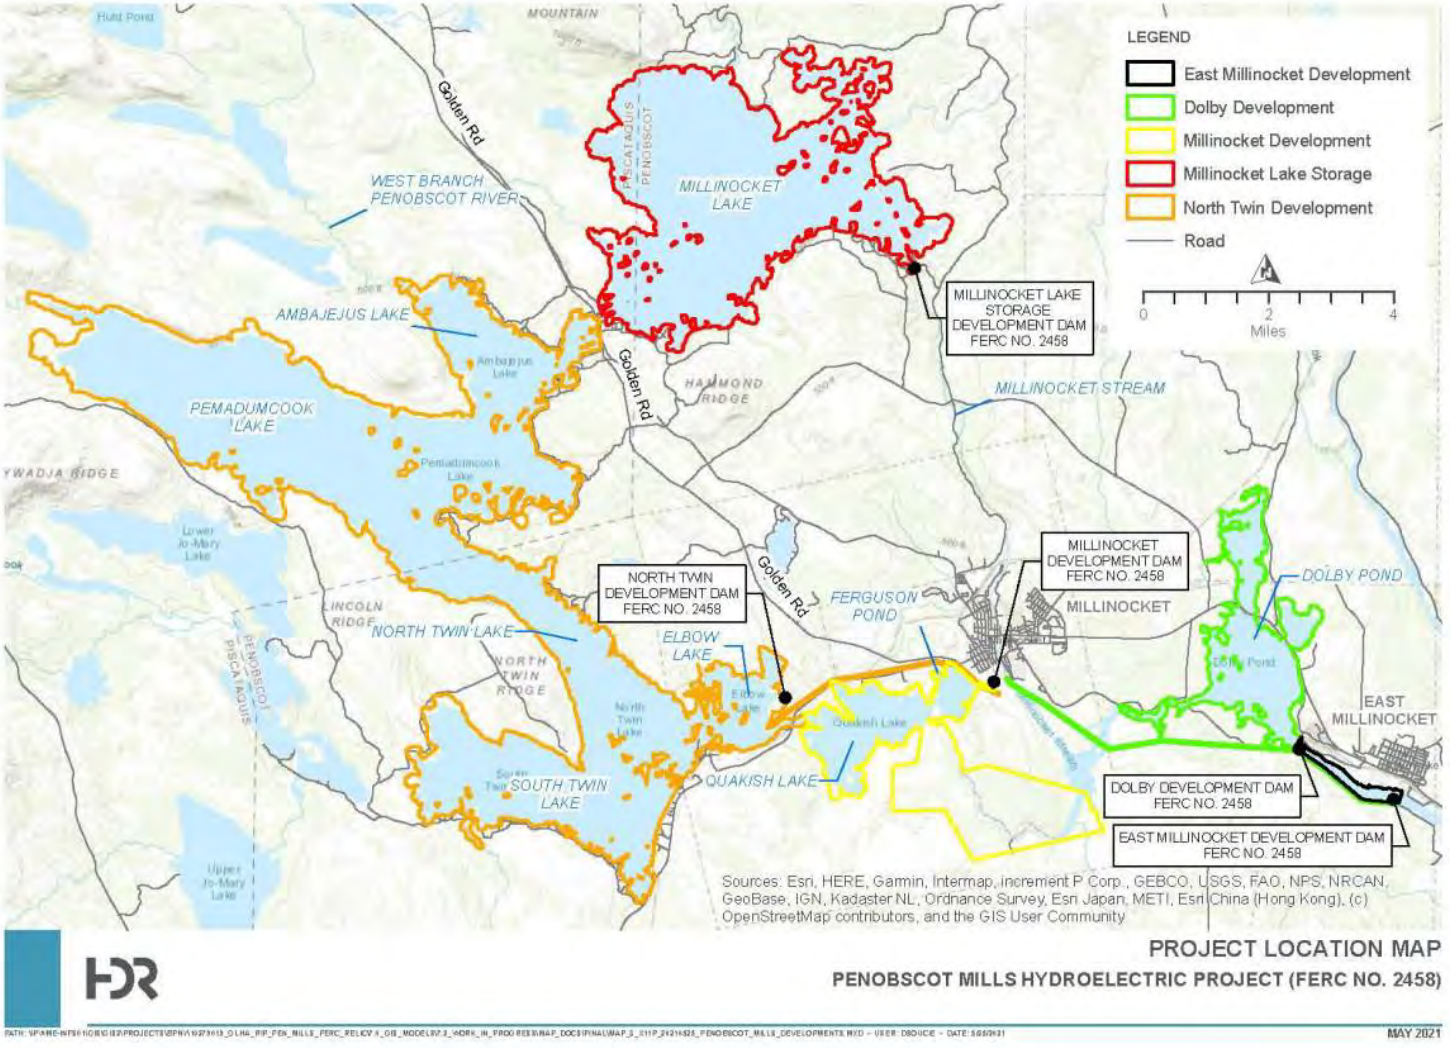

Figure 3. Penobscot Mills Hydroelectric Project Location Map (source: PAD).

**Millinocket Lake Storage Development (figure 4)** – Millinocket Lake has a normal full pond elevation of 480.0 feet, with a surface area of 8,640 acres. The lake has a mean depth of 23.6 feet. Usable storage of the lake is 45,370 acre-feet, with a 6.2-foot drawdown. Millinocket Lake is impounded by a 635-foot-long, concrete and earth-filled dam located on Millinocket Stream, at the outlet of Millinocket Lake. Millinocket Lake Storage Dam includes a 19-foot-long spillway section and an adjacent 58-foot-long gated section that contains four lift gates and one log sluice gate. The dam is located approximately 7.8 miles upstream of the Millinocket Development tailrace. The development's pumping station, which contains two pumps, is located on the west side of Millinocket Lake, about 6.2 miles from Millinocket Lake Storage Dam. Water is conveyed from the pumping station through two 544-foot-long, 4-foot, 6-inch-diameter steel pipes, which is then discharged to Ambajejus Lake through an outlet structure.

**North Twin Development (figure 5)** – The North Twin impoundment includes Elbow, South Twin, North Twin, Pemadumcook, and Ambajejus Lakes. The impoundment is about 11.8 miles long and has a surface area of approximately 17,790 acres at the normal full pond elevation of 491.92 feet. The impoundment's mean depth is 27.7 feet, and its usable storage is about 344,355 acre-feet with a drawdown of 22 feet. The North Twin impoundment is formed by North Twin Dam, which is a 1,051-foot-long concrete and earth-filled structure located at the outlet of Elbow Lake. The dam, which crosses the West Branch from southeast-northwest, includes a 500-foot-long, earthen dike; a 114-foot-wide intake structure and powerhouse; a 34-foot-wide fishway[9] section with two gated log sluices; a 117-foot-long Tainter gate section; and a 286-foot-long earthen embankment. In addition to the dam, there are six dikes, totaling 2,530 feet in length, retaining water.

Water flows from the North Twin impoundment through an intake structure to the powerhouse. The intake contains nine water passages, each 8 feet wide by 13 feet high and equipped with a steel gate to control the flow of water to the turbines. The intake is protected by trash racks with 2-5/8-inch clear bar spacing. The trash racks are cleaned with a trash rake. The 50-foot by 114-foot powerhouse, which is integral with, and located immediately downstream from the intake, contains two vertical fix-blade turbines and one vertical Kaplan turbine, each connected to a generator. The rated capacity of the three turbines is 7.0125 MW and the rated capacity of the three generators is 9.84 MW. Water exits the powerhouse through six tailrace bays and flows through a 104-foot-wide tailrace back to the West Branch.

[9] Flow to the 98-foot-long pool and weir fishway is controlled by three gates located at different depths upstream of the fishway. The upstream fishway provides passage for resident fish species (e.g., landlocked salmon).

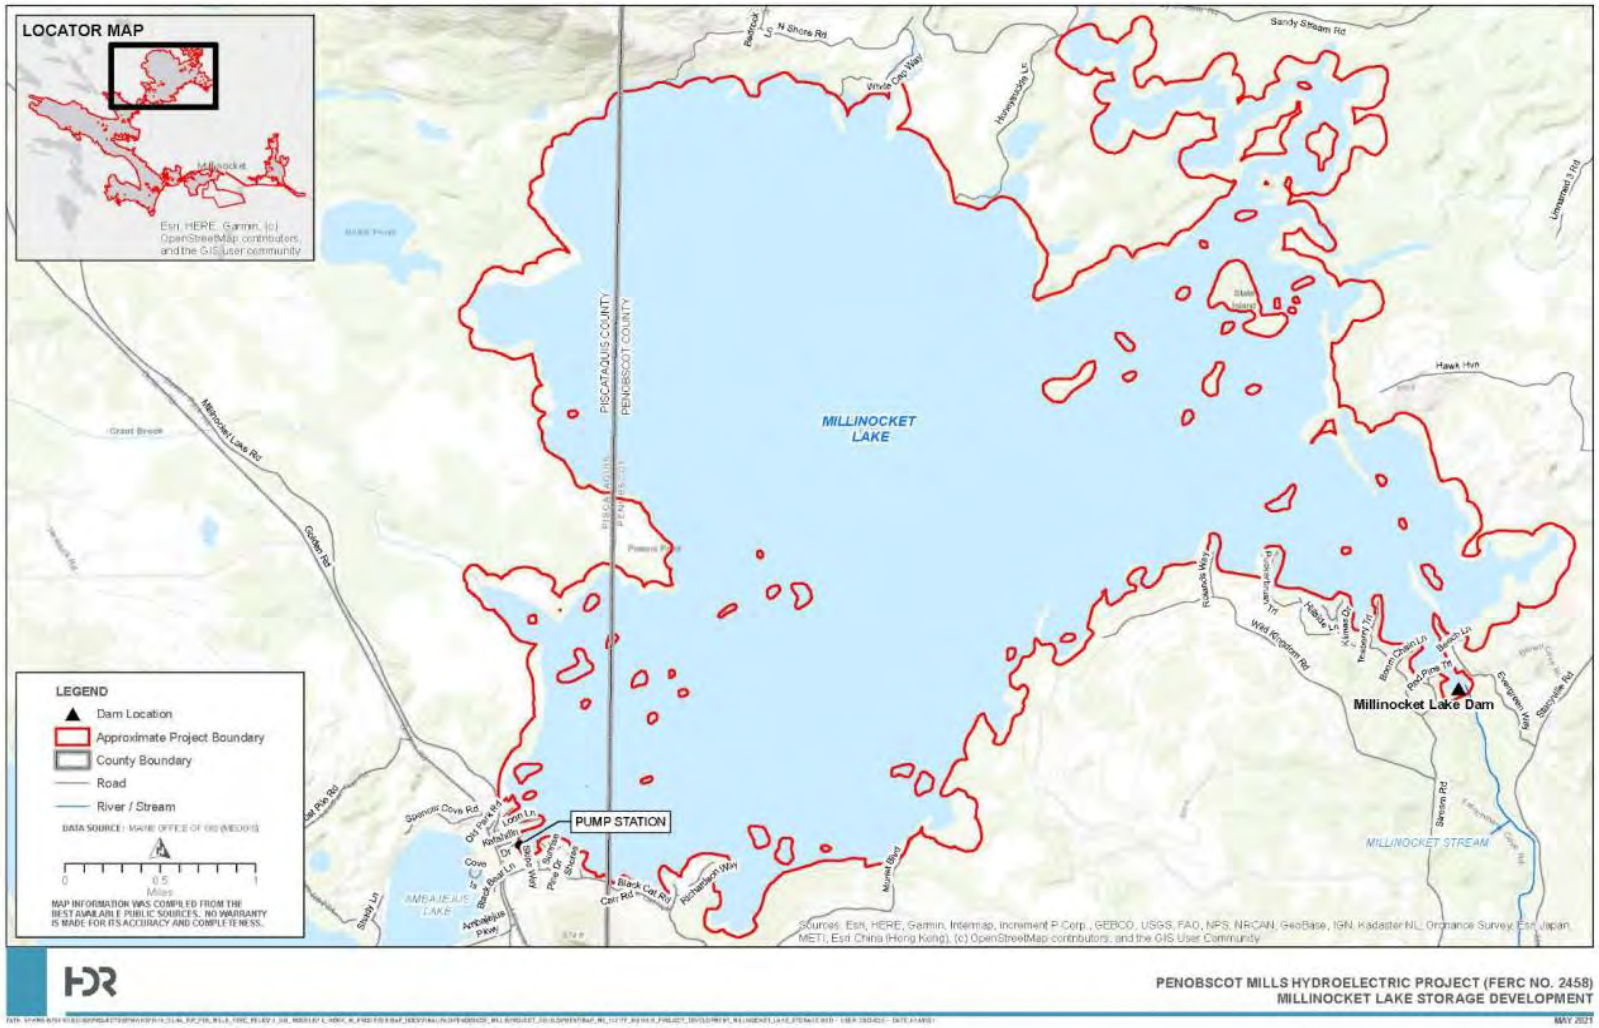

Figure 4. Millinocket Lake Storage Development facilities (source: PAD).

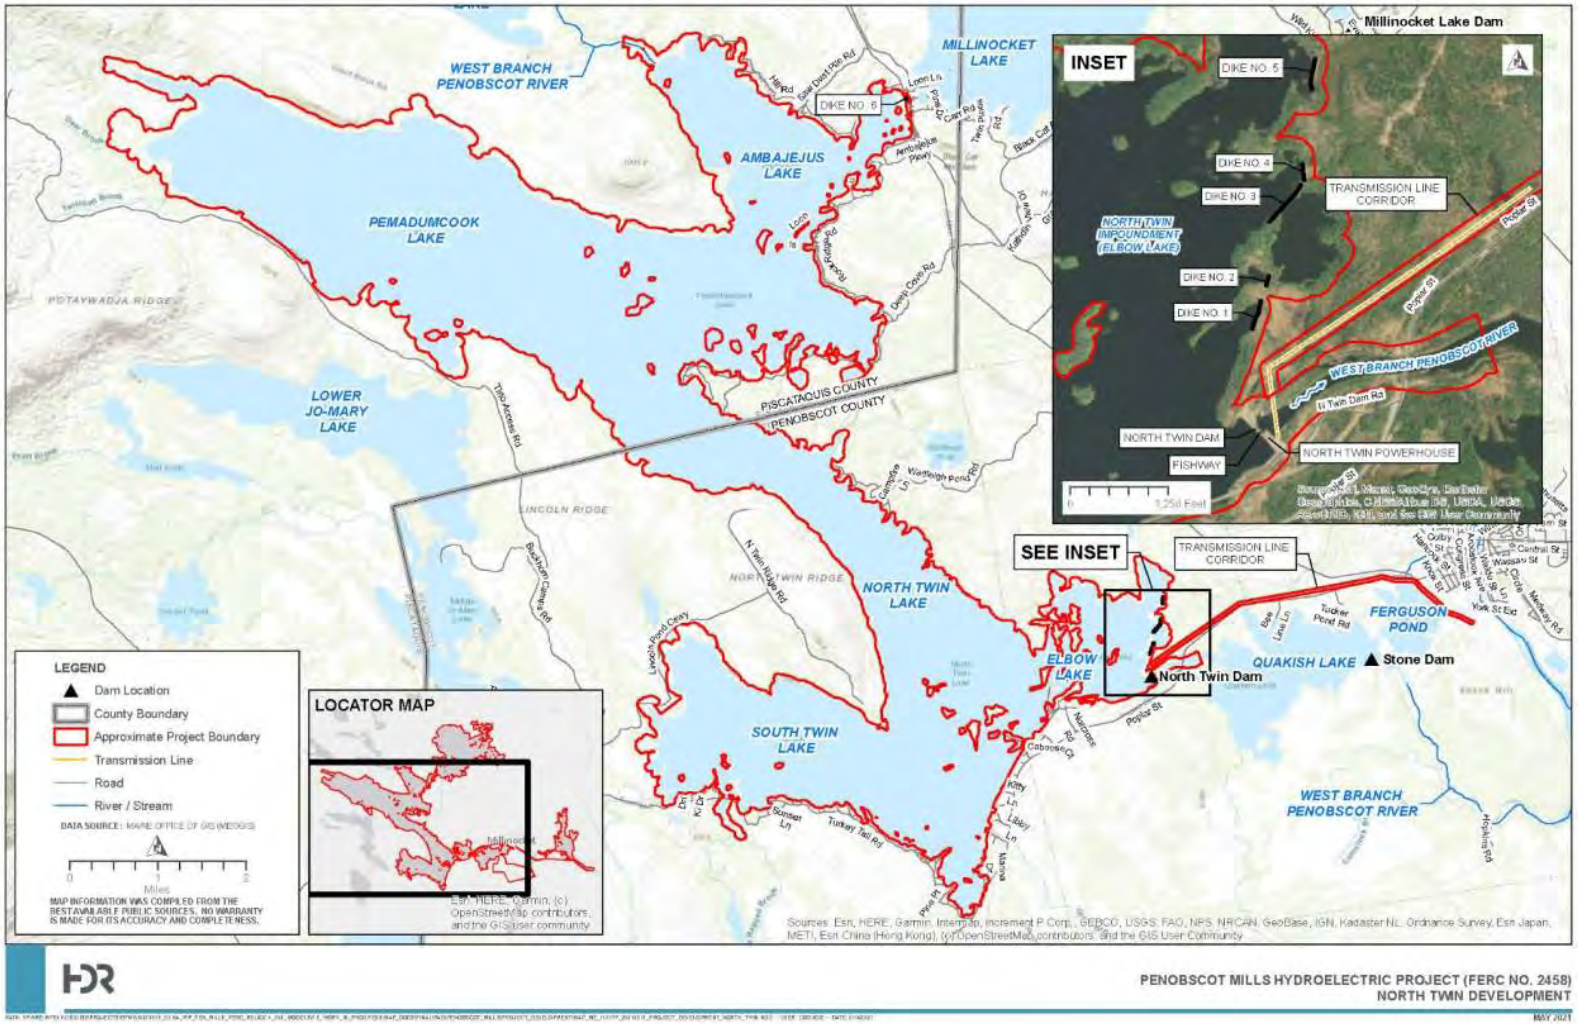

Figure 5. North Twin Development facilities (source: PAD).

The power generated by the North Twin Development is transmitted to the grid via an adjacent substation that contains six transformers and a 4.2-mile-long transmission line that extends to GLHA's Substation #4 located at the former Millinocket Mill.

**Millinocket Development (figure 6)** – The impoundment for the Millinocket Development consists of Quakish Lake and Ferguson Pond. The 8,600-foot-long Quakish Lake has a surface area of 1,344 acres at a normal full pond elevation of 458.7 feet. Quakish Lake and Ferguson Pond provide negligible storage. Stone Dam, a 1,262-foot-long, concrete structure, is located at the outlet of Quakish Lake. The dam directs water into the western canal, and consists of: (1) a 300-foot-long overflow spillway section with no flashboards; (2) a 358-foot-long spillway section with 30-inch-high flashboards; (3) a 52-foot-wide waste gate; (4) a 428-feet, 5-inch-long spillway with a 2-foot, 9-inch-high rubber, inflatable dam; and (5) a 124-foot-long gatehouse. In addition to Stone Dam, there are three dikes, with a total length of 1,854 feet, located along the north shore of Quakish Lake that retain water.

The gatehouse is integral with Stone Dam and is used to regulate flow into the 150-foot-wide by 1,400-foot-long western canal. The western canal conveys water from Quakish Lake to Ferguson Pond. Five earthen dikes, with a total length of 3,915 feet, are located along the perimeter of Ferguson Pond and are used to confine the area impounded by Ferguson Pond. From Ferguson Pond, water enters the 150-foot-wide by 1,300-foot-long eastern canal which conveys water from Ferguson Pond to an intake structure.

The intake structure contains seven gates. Six gates control flow into six 1,007-foot-long, 10-foot-diameter penstocks that lead to turbine-generator units in the 'Grinder Room.' The remaining gate controls flow into a 1024-foot-long, 11-foot-diameter penstock that leads to turbine-generator units in the 'Generator Room.' The 10-foot-diameter penstocks are protected by trash racks with 2-7/8-inch clear bar spacing, and the 11-foot-diameter penstock is protected by trash racks with 2-1/2-inch clear bar spacing. The 174.5-foot-wide by 210-foot-long Grinder Room contains five horizontal Francis turbine-generator units (Units 1, 3, 4, 5, and 6)[10] and the 52-foot-wide by 122-foot-long Generator Room contains two horizontal Francis turbine-generator units (Units 7 and 8). The rated capacity of the seven turbines is 37.3748 MW, and the rated capacity of the seven generators is 38.64 MW. Water exits the turbines through seven, 25-foot-wide tailrace bays that discharge directly to the West Branch.

[10] The Grinder Room also contains an inoperable turbine-generator unit (Unit 2), which does not contribute to the development's rated capacity.

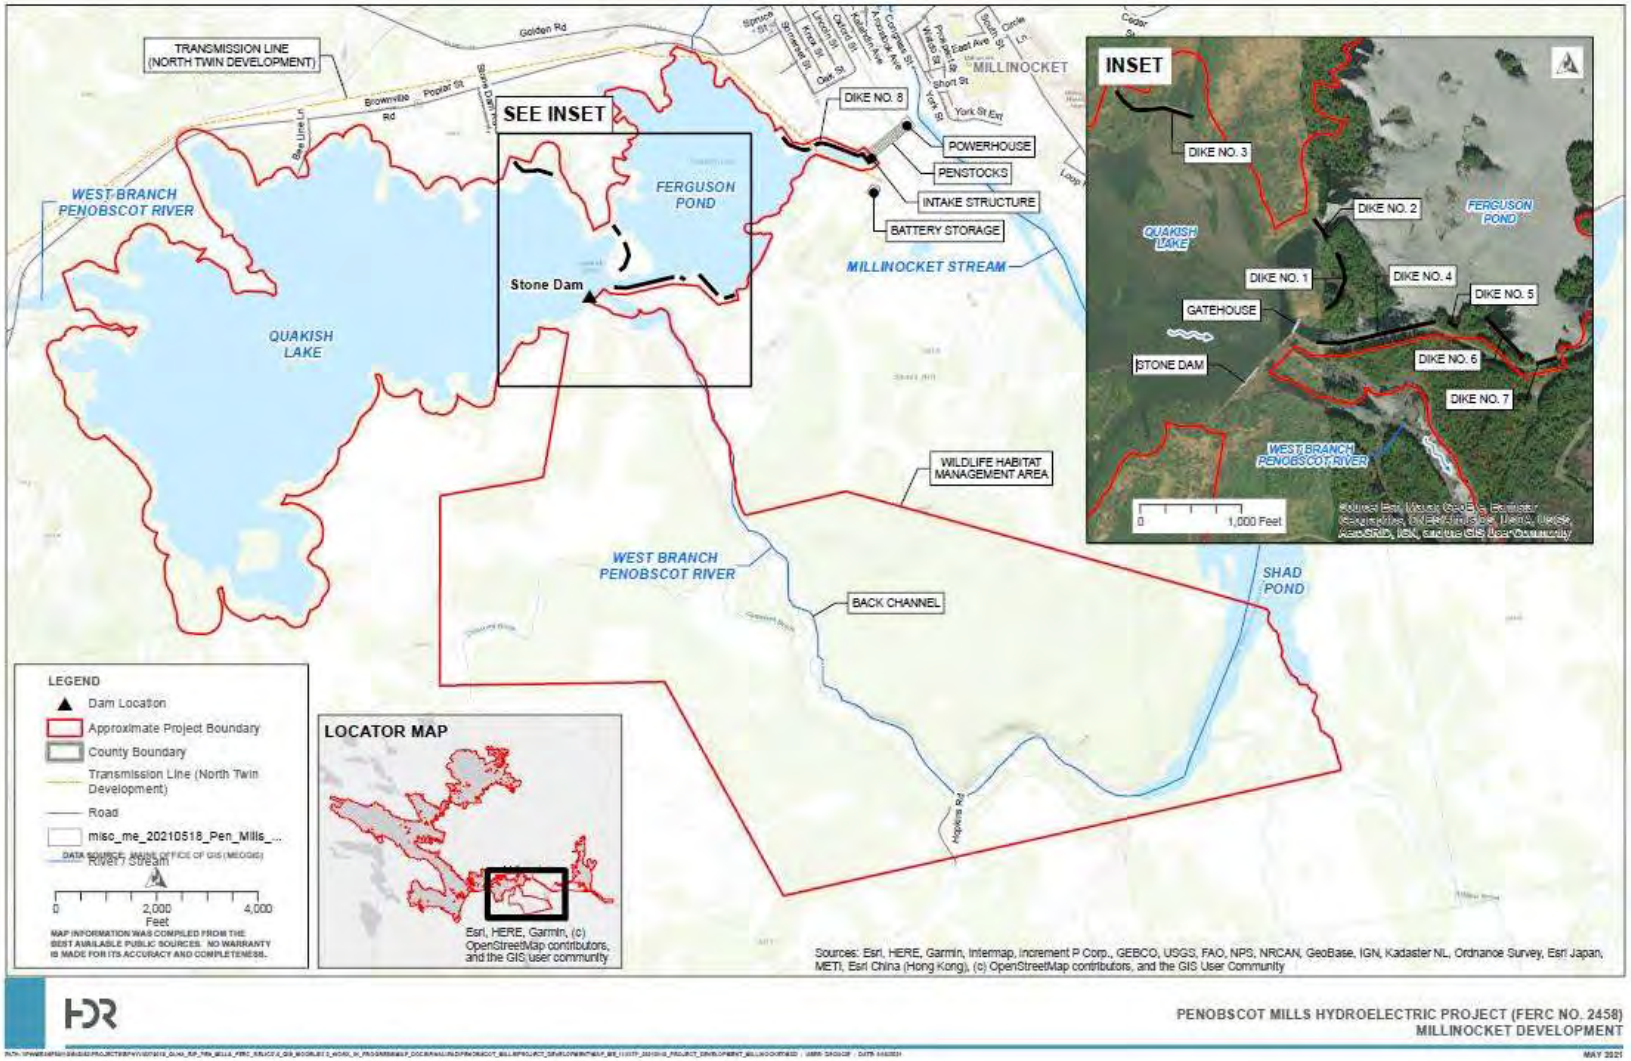

Figure 6. Millinocket Development facilities (source: PAD).

Power generated from Units 3, 4, 5, 6, and 7 is transmitted across Millinocket Stream via a 300-foot-long transmission line to a transformer in GLHA's Substation #1. Power generated from Units 1 and 8 is also transmitted across Millinocket Stream via a 300-foot-long transmission line to a second transformer in Substation #1.

**Dolby Development (figure 7)** – The 4.2-mile-long Dolby Pond has a surface area of 2,048 acres at a normal full pond elevation of 336.2 feet. Dolby Pond provides negligible storage. The 1,395-foot-long Dolby Dam is a concrete and earth-filled structure located at the outlet of Dolby Pond. The dam, which crosses the West Branch in a generally southwest-northwest direction, includes a 27-foot-long concrete abutment; four spillway sections with a total length of 521 feet; two 6-foot-long abutments; a 76-foot-wide waste gate; a 209-foot-wide intake with an integral powerhouse; and two contiguous earthen dikes, measuring 300 feet long and 250 feet long.

Water is withdrawn from Dolby Pond through a 23-foot-wide by 209-foot-long concrete intake structure with nine openings. Each opening is equipped with a headgate to control the flow of water to the turbines. Eight sets of trash racks, having a total length of 174 feet, extend across the upstream side of the intake. The trash racks for bays 2 through 4 have a clear bar spacing of 1-5/8 inches, and the trash racks for bays 5 through 8 have a clear bar spacing of 2-5/8 inches. The gate operators and trash rakes for bays 5 through 8 are housed in a 23-foot-wide by 121-foot-long concrete block building. Water flows from the intake to a 115-foot-wide by 167-foot-long powerhouse that houses four operable turbine-generator units (Units 5, 6, 7, and 8).[11] Three of the operable turbines are Inclined Kaplan units and one is a Fixed Blade unit, each connected to generators. The rated capacity of the four turbines is 17.049 MW, and the rated capacity of the four generators is 17.098 MW. Water exits the turbines through four tailrace bays and flows into a 189-foot-wide tailrace.

The power generated by the Dolby Development is transmitted to the grid via an adjacent substation that contains two transformers and a 2-mile-long transmission line that extends to GLHA's Substation #5.

[11] Units 1, 2, 3, and 4 in the Dolby Powerhouse are currently out-of-service, and do not contribute to the development's rated capacity.

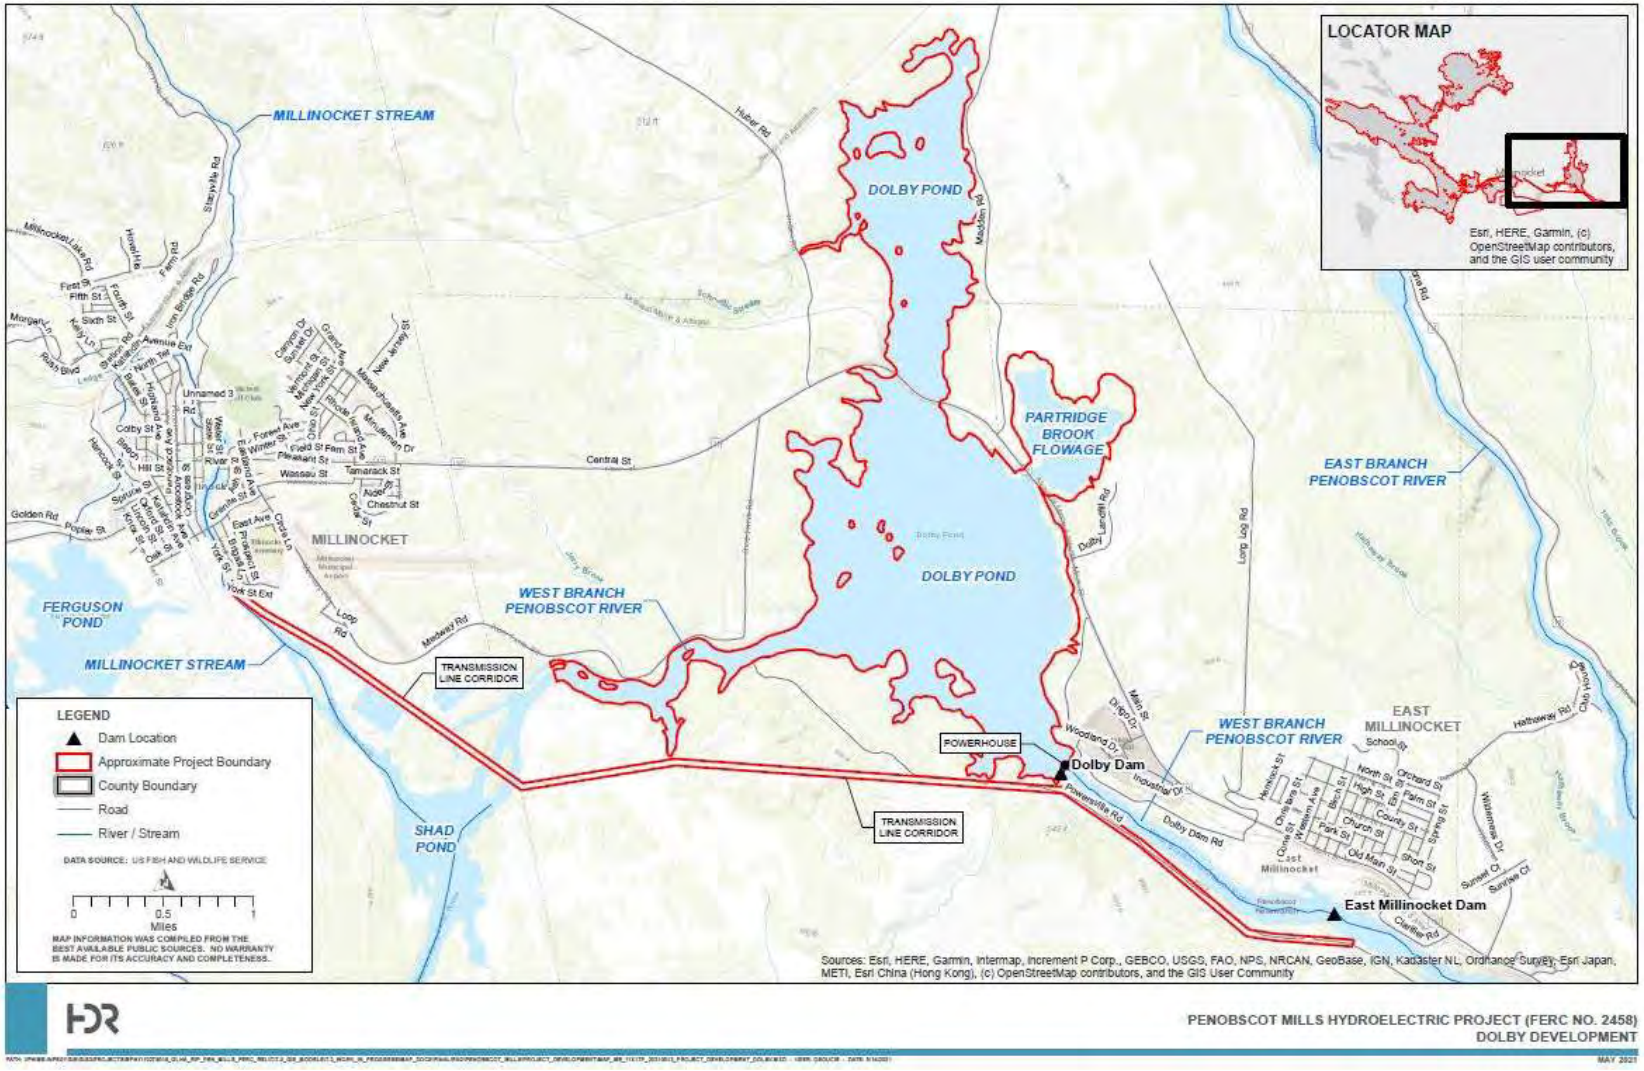

Figure 7. Dolby Development facilities (source: PAD).

**East Millinocket Development (figure 8)** – The East Millinocket Development is located at the former East Millinocket Mill, about 1.7 miles upstream of Black Bear Hydro Partners, LLC's Medway Hydroelectric Project No. 2666. The 1.9-mile-long East Millinocket impoundment extends upstream to the tailwater of the Dolby Development. The impoundment has a surface area of 128 acres at a normal full pond elevation of 287.2 feet and has negligible storage. The 717.5-foot-long East Millinocket Dam, which crosses the West Branch in a generally east-west direction, consists of a 116-foot-long earth embankment; a 212-foot-long spillway section; a 59-foot-wide waste gate; a 154-foot-long spillway section; a 7-foot-wide timber crib section; a 23-foot-wide sluice gate; and a 146.5-foot-wide intake structure integral with the powerhouse.

Water from the East Millinocket impoundment flows through a 146.5-foot-long by 54-foot-wide intake structure, containing 12, 9-foot by 11-foot gate openings. Each of 12 gate openings are equipped with a steel headgate connected to a hand-operated gate hoist that controls the flow of water into the intake. The intake is protected by trash racks that have a 1-1/4-inch clear bar spacing. From the intake, water flows into to six covered flumes in a 56-foot-wide by 146.5-foot-wide powerhouse. Each flume contains a horizontal Francis turbine connected to a generator. The rated capacity of the six turbines is 6.975 MW and the rated capacity of the six generators is 9.952 MW. Water exits the powerhouse and flows through a 1,050-foot-long tailrace (average width of 110 feet) to the West Branch.

The power generated by the East Millinocket Development is transmitted to the grid via two 6,900-volt buses, which are connected to a transformer that is part of Substation #3 located at the former East Millinocket Mill. From the transformer, power is transmitted to Substation #5 via a 2-mile-long transmission line.

**Battery Energy Storage System** – The Projects include two utility-scale battery energy storage sites that operate as a single Battery Energy Storage System. One of the battery storage sites is located at the Powersville Substation (within the transmission right-of-way for the Dolby and East Millinocket Developments). This battery storage site is sized at a capacity of 10 MW with a 2-hour duration (20 MWh total capacity). The second battery storage site is located within the Ripogenus Project's 115-kV (200-foot-wide) transmission line right-of-way adjacent to the Millinocket Substation #4 (partially within the Penobscot Mills Project boundary and partially within the Ripogenus Project boundary). This battery storage site is also sized at a capacity of 10 MW with a 2-hour duration (20 megawatt hours [MWh] total capacity). The Battery Energy Storage System has a total capacity of 20 MW for up to 2 hours (40 MWh total capacity).

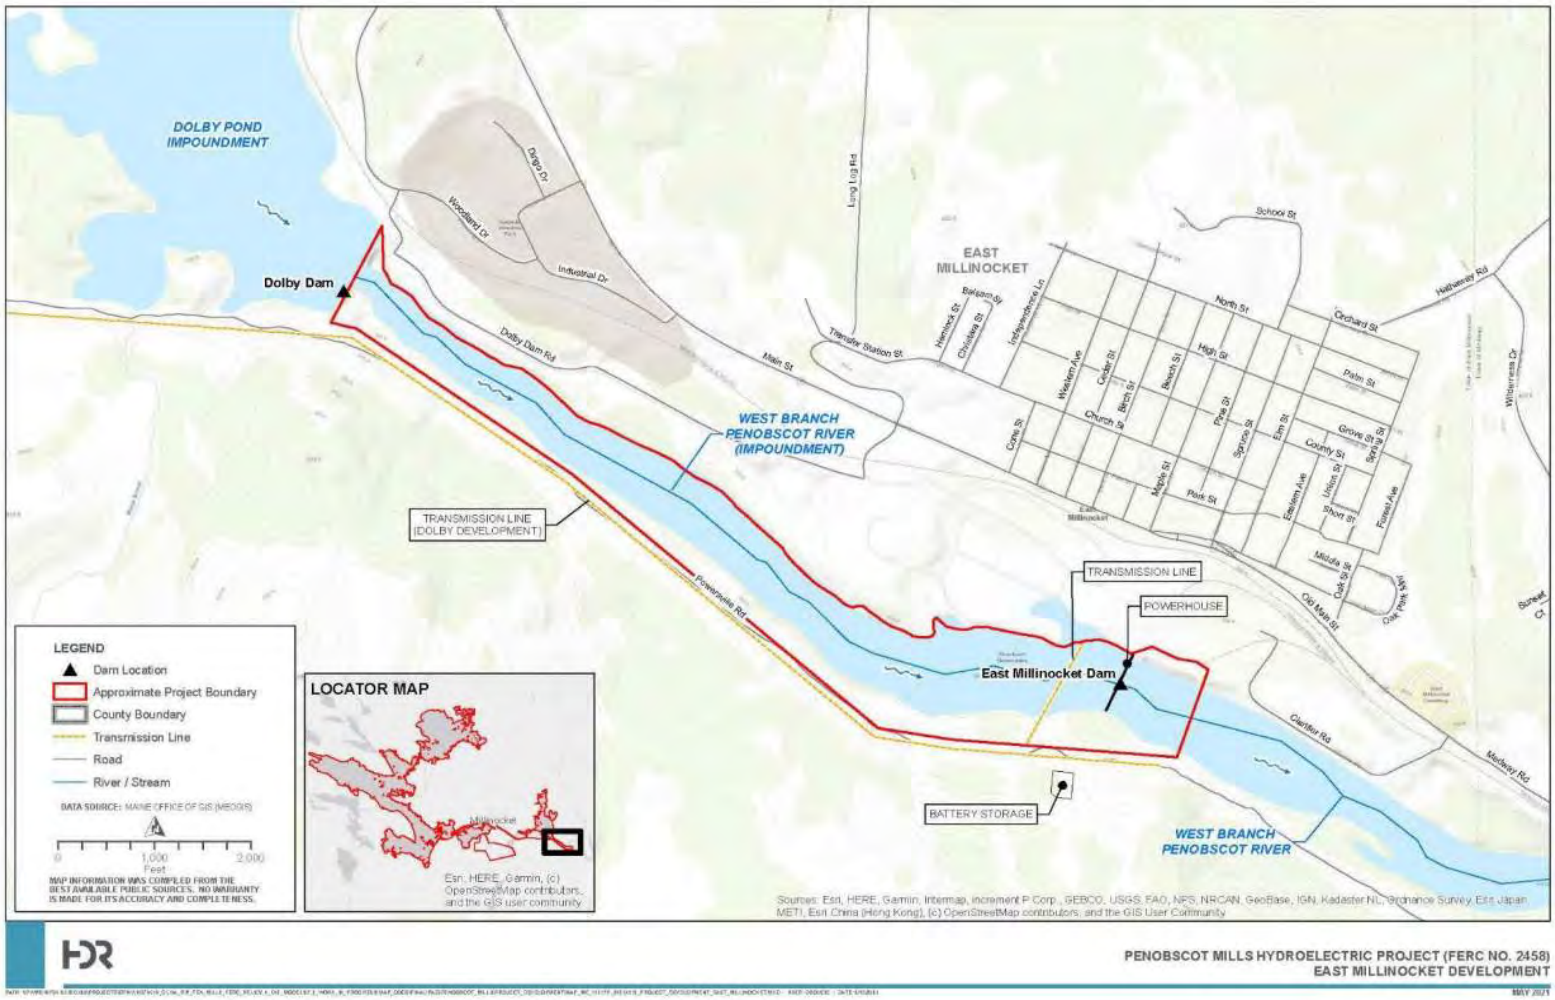

Figure 8. East Millinocket Development facilities (source: PAD).

### 3.1.2 Recreation Facilities

*RIPOGENUS PROJECT*

Ripogenus Project recreation facilities consist of a boat launch (Chesuncook Point Boat Launch), a boat put-in (Caribou Lake Put-In), 12 campsites (Chesuncook Lake Remote Campsites-10; Umbazooksus Stream Campsites-2), rafting put-in facilities (McKay Station Rafting Put-In Site), and a 0.75-mile-long trail (Upper Gorge Trail).

*PENOBSCOT MILLS PROJECT*

Penobscot Mills Project recreation facilities consist of six boat launches. The Millinockett Lake Public Boat Launch is located at the Millinocket Lake Storage Development. The Ambajejus Lake Boat Launch and South Twin Lake (Partridge Cove) Boat Launch are located at the North Twin Development. The Green Bridge Boat Launch is located at the Millinocket Development. The Dead Man's Curve Boat Launch and Dolby Pond (Flowage) Boat Launch are located at the Dolby Development.

### 3.1.3 Project Operation

*RIPOGENUS PROJECT*

The Ripogenus Project operates as a store-and-release facility with an annual seasonal drawdown that allows for management of water levels and flows downstream of the project. The normal full pond elevation of the Ripogenus impoundment is 941.6 feet, with a maximum drawdown of 44 feet (based on operational limitations of the project). During normal operation and normal inflow years, the Ripogenus impoundment elevation is held relatively stable at 941.6 feet during the summer months and is gradually drawn down starting in the fall, with a target low elevation of 913.6 feet by late winter, in anticipation of spring thaw and high flows. This operation results in a target seasonal drawdown of 28 feet. In the spring, the Ripogenus impoundment elevation rises based on inflows from the upstream Storage Project No. 2634, spring thaw, and precipitation, with the goal of reaching 941.6 feet by late spring. In coordination with the upstream Storage Project and the downstream Penobscot Mills Project, Ripogenus Project operators balance downstream flows and water levels to support flood control, public safety, dam safety, supplemental flows during seasonal low-flow periods, fish spawning and migration, recreation and whitewater boating, water quality, and generation needs.

GLHA also provides a minimum flow of 100 cubic feet per second (cfs) through sluice gates into the bypassed reach (Upper Gorge) from July 1 through September 30 and 12 cfs through leakage from Ripogenus Dam from October 1 through June 30. In

addition, the project provides seasonally variable minimum flows downstream of McKay Station into the West Branch, according to the schedule in table 1, to facilitate drawdown of the North Twin impoundment, protect landlocked salmon spawning, and provide whitewater recreation flows. During failure of the generating units, the project releases 400 cfs.

Table 1. Minimum flows released from McKay Station into the West Branch. (Source: PAD).

| Date range | Minimum flow released |
|---|---|
| **Facilitate North Twin impoundment drawdown** | |
| September 16 through October 14 | 1,000 cfs |
| **Landlocked salmon flows** | |
| October 15 through November 15 | At least 1,422 cfs, or inflow, but not less than 1,300 cfs at any time.[a] |
| November 16 through June 7 | Greater than 1,422 cfs.[a] |
| **Whitewater recreation flows** | |
| May 1 through September 15 (8:30 AM - 5:00 PM) | **Normal hydrologic year:**<br>2,300 cfs on Saturdays and Sundays<br>2,200 cfs on Mondays and Fridays<br>2,000 cfs on Tuesdays through Thursdays<br>**Wet or dry hydrologic year:**<br>2,200 cfs on Saturdays and Sundays<br>2,000 cfs on Mondays and Fridays<br>1,800 cfs on Tuesdays through Thursdays |
| September 16 to October 1 (8:30 AM - 5:00 PM) | **Normal hydrologic year:**<br>2,300 cfs on Saturdays and Sundays<br>**Wet or dry hydrologic year:**<br>2,200 cfs on Saturdays and Sundays |
| June 8 to October 14 (5:00 PM - 8:30 AM) | 1,000 cfs |

[a] Actual flows are established each year in consultation with the U.S. Fish and Wildlife Service and Maine Department of Inland Fisheries and Wildlife.

GLHA also uses the Ripogenus Project to provide flows that are diverted to the Holbrook Side Channel from the West Branch.[12] Two pipes are used for this purpose. One is equipped with a valve that can be opened or closed to increase or reduce flows from the West Branch into the channel; the other has no valve to control flow. Flows from the channel re-enter the West Branch about 1,000 feet downstream from the pipes. Flows into the channel range from about 35 cfs to 65 cfs during normal operating conditions, depending on the amount of flow in the West Branch. On about June 1, GLHA closes the valve to reduce flow into the channel to enhance conditions for landlocked salmon and brook trout fry emergence and production. On about October 15, GLHA opens the valve to increase flow into the channel to enhance conditions for landlocked salmon and brook trout spawning.

*PENOBSCOT MILLS PROJECT*

The five developments that compose the Penobscot Mills Project are operated as an integrated system, primarily making use of flows received from the Ripogenus Project. The two store-and-release developments (Millinocket Lake Storage and North Twin) are located upstream of the run-of-river developments (Millinocket, Dolby, and East Millinocket). The North Twin impoundment receives flow from the Ripogenus Project. Flow from the Millinocket Lake Storage Development is either pumped into Ambajejus Lake (part of the North Twin impoundment) or flows down Millinocket Stream and enters the West Branch downstream from the Millinocket Development.

**Millinocket Lake Storage Development** – GLHA operates the Millinocket Lake Storage Development solely as a storage development, with no hydropower facilities. The development is operated as part of the larger West Branch system to manage flows and water levels within the West Branch and downstream in the Mainstem Penobscot River. GLHA maintains the water level in Millinocket Lake between elevations 470.0 feet and 480.0 feet (normal full pond elevation) by either pumping water via the development's pumping station to the North Twin impoundment (typically to maintain required impoundment levels within the North twin impoundment), or by releasing water into Millinocket Stream. In addition, GLHA releases a minimum flow of 60 cfs from Millinocket Lake into Millinocket Stream from May 1 through October 15, and a minimum flow of 60 cfs or inflow, whichever is less, from October 16 through April 30.

**North Twin Development** – Consistent with the operation of the Millinocket Lake Storage Development and the Ripogenus Project, the North Twin Development is

[12] The Holbrook Side Channel is a 1,400-foot-long channel located adjacent to the West Branch approximately 1.7 RM downstream from Ripogenus Dam.

operated to support flow management and water levels in the West Branch and the mainstem Penobscot River. The North Twin Development operates as a store-and-release facility, with a normal full pond elevation of 491.92 feet. Pursuant to the current license, GLHA maintains the North Twin impoundment above elevation 488.42 feet (within 3.5 feet from normal full pond). From October 15 to the start of the spring freshet season, the impoundment elevation is gradually drawn down to an elevation of 479.42 feet (12 feet below normal full pond). However, during periods of high inflows, GLHA may use more than 12 feet of storage in the North Twin impoundment. From ice out to August 22, the impoundment is refilled and is maintained within plus or minus 0.5 foot of a target elevation of 490.42 feet (or within 1.5 feet from normal full pond elevation).

In addition to maintaining impoundment levels, GLHA releases a minimum flow of 3,000 cfs from the North Twin Development from August 22 through October 15, provided the impoundment elevation exceeds 488.42 feet. If the 488.42-foot elevation is not met, GLHA releases a minimum flow of 2,000 cfs from the North Twin Development to meet the 2,000-cfs minimum flow requirement at Shad Pond (located downstream from the Millinocket and Millinocket Lake Storage Developments).

The North Twin Development is equipped with a pool-and-weir fishway. GLHA maintains a stable impoundment elevation from May 1 through August 22 for recreation purposes, which also provides a suitable impoundment elevation for the fishway exit. In addition, GLHA provides an attraction flow of 3.5 cfs through an 8-inch-diamater gravity pipe that extends from the dam to the fishway entrance.

**Millinocket, Dolby, and East Millinocket Developments** – GLHA operates the Millinocket, Dolby, and East Millinocket Developments in a run-of-river mode, with typical impoundment fluctuations of 1 foot or less from the top of the flashboards when installed or crest of dam without flashboards. In addition, GLHA releases a minimum flow of 2,000 cfs through each development to the West Branch, as measured downstream from Shad Pond. Run-of-river operation and the minimum flows are accomplished through use of the developments' turbines. If use of the turbines is not possible, GLHA uses the inflatable, rubber dam at Stone Dam at the Millinocket Development and waste gates at the Dolby and East Millinocket Development to support run-of-river operations.

**Battery Energy Storage System** – In 2020, GLHA installed a utility-scale Battery Energy Storage System at the Projects. One battery storage site is located at the Millinocket Substation #4 and the other is located the Powersville Substation. The Battery Energy Storage System is connected to the Project's transmission lines and collects power from the Projects at 34.5 kV and delivers it to the grid at 115 kV. The two

battery storage sites can be isolated from the substations using breakers and switches, if necessary. The system only charges from the hydroelectric facilities, and not from the grid. The system has not, and would not, change how the Projects are operated.

### 3.1.4 Proposed Environmental Measures

GLHA proposes to continue to operate and maintain the Ripogenus Project and the Penobscot Mills Project as required by their current licenses. GLHA does not propose any new development or changes in project operation. The environmental measures that are currently proposed by GLHA are described below.

**Aquatic Resources**

- Continue to provide seasonally variable minimum flows from Ripogenus Dam into Upper Gorge and from McKay Station into the West Branch as described above in table 1.

- Continue to provide flows to the Holbrook Side Channel for landlocked salmon and brook trout spawning and rearing as describe above in table 1.

- Continue to provide the seasonal minimum flows described above from Millinocket Lake Storage Dam into Millinocket Stream.

- Continue to provide the minimum flows described above from North Twin Dam, as well as the Millinocket, Dolby, and East Millinocket Developments to the West Branch.

**Wildlife and Botanical Resources**

- Continue to deploy artificial nesting platforms for the Common Loon and other aquatic birds in the Ripogenus impoundment.

- Continue to implement and maintain the wildlife enhancement measures included in the Wildlife management Plan required by Article 412 of the current license for the Wildlife Management Area located adjacent to the Back Channel downstream from Stone Dam.

**Recreation Resources**

- Continue to operate and maintain the 11 recreation sites described above for the Projects.

- Continue to collect recreation use information every 6 years for the project recreation sites.

- Continue to provide whitewater boating flows downstream from McKay Station, as described above in table 1.

- Update the existing Recreation Plans for the Projects as part of the license applications.

**Cultural Resources**

- Develop updated Historic Properties Management Plans for the Projects.

## 3.2 DAM SAFETY

It is important to note that dam safety constraints may exist and should be taken into consideration in the development of proposals and alternatives considered in the pending proceedings. For example, proposed modifications to dam structures could impact the integrity of the dams' structures. As the proposals and alternatives are developed, the applicant must evaluate the effects and ensure that the Projects would meet the Commission's dam safety criteria found in Part 12 of the Commission's regulations and the Engineering Guidelines (http://www.ferc.gov/industries/hydropower/safety/guidelines/eng-guide.asp).

## 3.3 ALTERNATIVES TO THE PROPOSED ACTIONS

Commission staff will consider and assess all alternative recommendations for operational or facility modifications, as well as protection, mitigation, and enhancement measures identified by the Commission, the agencies, Native-American tribes, NGOs, and the public.

## 3.4 ALTERNATIVES CONSIDERED BUT ELIMINATED FROM DETAILED STUDY

At present, we propose to eliminate the following alternatives from detailed study in the NEPA document.

### 3.4.1 Federal Government Takeover

In accordance with § 16.14 of the Commission's regulations, a federal department or agency may file a recommendation that the United States exercise its right to take over a hydroelectric power project with a license that is subject to sections 14 and 15 of the FPA.[13] We do not consider federal takeover to be a reasonable alternative. Federal takeover of the Projects would require congressional approval. While that fact alone would not preclude further consideration of this alternative, there is currently no evidence showing that federal takeover should be recommended to Congress. No party has suggested that federal takeover would be appropriate, and no federal agency has expressed interest in operating the Projects.

### 3.4.2 Non-power License

A non-power license is a temporary license the Commission would terminate whenever it determines that another governmental agency is authorized and willing to assume regulatory authority and supervision over the lands and facilities covered by the non-power license. At this time, no governmental agency has suggested a willingness or ability to take over the Projects. No party has sought a non-power license for either project, and we have no basis for concluding that the Ripogenus and Penobscot Mills Projects should no longer be used to produce power. Thus, we do not consider a non-power license a reasonable alternative to relicensing the projects.

### 3.4.3 Project Decommissioning

As the Commission has previously held, decommissioning is not a reasonable alternative to relicensing in most cases.[14] Decommissioning can be accomplished in different ways depending on the project, its environment, and the particular resource needs.[15] For these reasons, the Commission does not speculate about possible

[13] 16 U.S.C. §§ 791(a)-825(r).

[14] *See, e.g., Eagle Crest Energy Co*., 153 FERC ¶ 61,058, at P 67 (2015); *Public Utility District No. 1 of Pend Oreille County*, 112 FERC ¶ 61,055, at P 82 (2005); *Midwest Hydro, Inc*., 111 FERC ¶ 61,327, at PP 35-38 (2005).

[15] In the unlikely event that the Commission denies relicensing a project or a licensee decides to surrender an existing project, the Commission must approve a surrender "upon such conditions with respect to the disposition of such works as may be determined by the Commission." 18 C.F.R. § 6.2 (2020). This can include simply shutting down the power operations, removing all or parts of the project (including the

decommissioning measures at the time of relicensing, but rather waits until an applicant actually proposes to decommission a project, or a participant in a relicensing proceeding demonstrates that there are serious resource concerns that cannot be addressed with appropriate license measures and that make decommissioning a reasonable alternative.[16] GLHA does not propose decommissioning, nor does the record to date demonstrate there are serious resource concerns that cannot be mitigated if the projects are relicensed; as such, there is no reason, at this time, to include decommissioning as a reasonable alternative to be evaluated and studied as part of staff's NEPA analysis.

# 4.0 SITE-SPECIFIC RESOURCE ISSUES

## 4.1 RESOURCE ISSUES

In this section, we present a preliminary list of environmental issues to be addressed in the NEPA document. We identified these issues, which are listed by resource area, by reviewing the PAD and the Commission's record for the Ripogenus Project and Penobscot Mills Project. The environmental issues identified apply to both projects, unless otherwise specified in the issue description. This list is not intended to be exhaustive or final, but contains those issues raised to date that could have substantial effects. After the scoping process is complete, we will review the list and determine the appropriate level of analysis needed to address each issue in the NEPA document.

### 4.1.1 Geologic and Soils Resources

- Effects of continuing to operate the Projects on shoreline erosion in the impoundments.

### 4.1.2 Water and Aquatic Resources

- Effects of continuing to operate the Projects (e.g., seasonal store-and-release operation of the Ripogenus Project and the Penobscot Mills Project's Millinocket Lake Storage and North Twin Developments) on

dam), or restoring the site to its pre-project condition.

[16] *See* generally *Project Decommissioning at Relicensing*; Policy Statement, FERC Stats. & Regs., Regulations Preambles (1991-1996), ¶ 31,011 (1994); *see also City of Tacoma, Washington,* 110 FERC ¶ 61,140 (2005) (finding that unless and until the Commission has a specific decommissioning proposal, any further environmental analysis of the effects of project decommissioning would be both premature and speculative).

water quantity and flow in the West Branch, including effects on impoundment water levels and flooding downstream.

- Effects of continuing to operate the Projects on DO concentrations and water temperature in the project impoundments and project-affected reaches downstream from project dams and powerhouses (e.g., Upper Gorge, Holbrook Side Channel, Back Channel, Millinocket Stream, and reaches of the West Branch).

- Effects of the drawdowns of the Ripogenus, North Twin, and Millinocket Lake impoundments on access to impoundment tributaries for resident fish (e.g., landlocked salmon and rainbow smelt).

- Effects of continuing to operate the Projects on aquatic habitat for resident fish and freshwater mussel species in the project impoundments and project-affected reaches downstream from project dams and powerhouses (e.g., Upper Gorge, Holbrook Side Channel, Back Channel, Millinocket Stream, and reaches of the West Branch).

- Effects of continuing to operate the Projects on upstream and downstream passage of American eels in the West Branch.

- Effects of continuing to operate the Projects on the movement of sea-run Atlantic salmon and alosines (American shad and river herring) in the West Branch and mainstem Penobscot River.

- Effects of continuing to operate the Projects on essential fish habitat for Atlantic salmon.

- Effects of continuing to operate the Projects on fish impingement, entrainment, and survival at the Projects' developments.

- Effects of continuing to operate the Projects on state-protected aquatic species (e.g., brook floater, yellow lampmussel, and tidewater mucket).

### 4.1.3 Wildlife and Botanical Resources

- Effects of continuing to operate the Projects on wetlands, as well as littoral and riparian habitat in, and along, the project impoundments.

- Effects of continuing to operate the Projects on state-protected wildlife and plant species (e.g., little brown bat, eastern small-footed bat, and wood turtle).

### 4.1.4 Threatened and Endangered Species

- Effects of continuing to operate and maintain the Projects on the federally threatened Canada lynx and its designated habitat, northern long-eared bat, and the federally endangered Gulf of Maine Distinct Population Segment Atlantic salmon and its designated critical habitat.[17]

### 4.1.5 Recreation and Land Use

- Effects of continuing to operate and maintain the Projects on the project recreation facilities and their use, as well as recreational opportunities on the West Branch.

- Adequacy of existing project recreational facilities to meet existing and future recreational demand and capacity requirements.

- Adequacy of existing whitewater flows and access on the West Branch downstream from McKay Station.

### 4.1.6 Cultural Resources

- Effects of continuing to operate and maintain the Projects on properties that are included in, or eligible for inclusion in, the National Register of Historic Places.

### 4.1.7 Developmental Resources

- Effects of proposed or recommended environmental measures on the Projects' generation and economics.

[17] This list is derived from our July 28, 2021 search of the U.S. Fish and Wildlife Service's ECOS-IPaC website.

## 5.0 PROPOSED STUDIES

GLHA's initial study proposals are identified by resource area for the Ripogenus Project (table 2) and the Penobscot Mills Project (table 3). Detailed information on GLHA's initial study proposals can be found in Section 6.2, *Proposed Studies and Information Gathering Associated with Identified Issues*, of the PAD. Further studies may need to be added to this list based on comments provided to the Commission and GLHA from interested participants, including Native-American tribes.

**Table 2**. GLHA's initial study proposals for the Ripogenus Project. (Source: PAD).

| Resource area | Proposed Study |
|---|---|
| **Aquatic Resources** | |
| *Water Quality* | Collect water quality data in project impoundment, Upper Gorge, and downstream of McKay Station to inform FERC relicensing and the water quality certification process. |
| *Macroinvertebrate Community* | Conduct a survey to characterize the macroinvertebrate community downstream from McKay Station. |
| **Recreation, Land Use, and Aesthetics** | |
| *Recreation Facilities* | Characterize the existing recreation facilities in the project boundary, including their condition. |

**Table 3**. GLHA's initial study proposals for the Penobscot Mills Project. (Source: PAD).

| Resource area | Proposed Study |
|---|---|
| **Aquatic Resources** | |
| *Water Quality* | Collect water quality data in the impoundments and riverine/tailwater areas of each development to inform FERC relicensing and the water quality certification process. |

| Resource area | Proposed Study |
|---|---|
| *Macroinvertebrate Community* | Conduct a survey to characterize the macroinvertebrate community in each of the tailwater and riverine reaches. |
| *Aquatic Habitat* | Map and characterize aquatic and riparian mesohabitat types in the Millinocket Development's Back Channel under the existing flow regime. |
| **Recreation, Land Use, and Aesthetics** | |
| *Recreation Facilities* | Characterize the existing recreation facilities in the project boundary, including their condition. |

## 6.0 REQUEST FOR INFORMATION AND STUDIES

We are asking federal, state, and local resource agencies, Native-American tribes, NGOs, and the public to forward to the Commission any information that will assist us in conducting an accurate and thorough analysis of the project-specific effects associated with relicensing the Ripogenus Project and the Penobscot Mills Project. The types of information requested include, but are not limited to:

- information, quantitative data, or professional opinions that may help define the scope of the analysis, and that helps identify significant environmental issues;

- identification of, and information from, any other EA, EIS, or similar environmental study (previous, on-going, or planned) relevant to the proposed relicensing of the Ripogenus Project and the Penobscot Mills Project;

- existing information and any data that would help characterize environmental conditions and habitats and in the assessment of project effects on environmental resources;

- the identification of any relevant federal, state, or local resource plans, documentation showing why any resources should be excluded from further study or consideration; and

- study requests by federal and state agencies, local agencies, Native-American tribes, NGOs, and the public that would help provide a framework for collecting pertinent information on the resource areas under consideration necessary for the Commission to prepare the NEPA document for the Projects.

All requests for studies filed with the Commission must meet the criteria found in Appendix A, *Study Plan Criteria*.

The requested information, comments, and study requests should be submitted to the Commission no later than October 9, 2021. All filings must clearly identify the following on the first page: **Ripogenus Hydroelectric Project (P-2572-133)** and/or **Penobscot Mills Hydroelectric Project (P-2458-247)**. Scoping comments may be filed electronically via the Internet. *See* 18 C.F.R. 385.2001(a)(1)(iii) and the instructions on the Commission's website at http://www.ferc.gov/docs-filing/efiling.asp. Commenters can submit brief comments up to 6,000 characters, without prior registration, using the eComment system at http://www.ferc.gov/docs-filing/ecomment.asp. You must include your name and contact information at the end of your comments. For assistance, please contact FERC Online Support at Mailto:FERCOnlineSupport@ferc.gov, or toll free at 1-866-208-3676, or for TTY, (202) 502-8659. In lieu of electronic filing, you may submit a paper copy. Submissions sent via the U.S. Postal Service must be addressed to: Kimberly D. Bose, Secretary, Federal Energy Regulatory Commission, 888 First Street NE, Room 1A, Washington, DC 20426. Submissions sent via any other carrier must be addressed to: Kimberly D. Bose, Secretary, Federal Energy Regulatory Commission, 12225 Wilkins Avenue, Rockville, Maryland 20852.

Register online at http://www.ferc.gov/esubscription.asp to be notified via email of new filings and issuances related to these or other pending projects. For assistance, please contact FERC Online Support at Mailto:FERCOnlineSupport@ferc.gov.

Any questions concerning the scoping meetings or how to file written comments with the Commission should be directed to Allan Creamer at (202) 502-8365, or allan.creamer@ferc.gov. Additional information about the Commission's licensing process, as well as the Ripogenus Project and the Penobscot Mills Project, may be obtained from the Commission's website, www.ferc.gov.

## 7.0 INITIAL PROCESSING SCHEDULE

The decision on whether to prepare and EA or EIS will be determined after the license application is filed and we fully understand the scope of effects and measures under consideration. The NEPA document will be distributed to all persons and entities on the Commission's service and mailing lists for the Ripogenus Project and the

Penobscot Mills Project. The NEPA document will include our recommendations for operating procedures, as well as environmental protection and enhancement measures that should be part of any license issued by the Commission. The comment period will be specified in the notice of availability of the NEPA document.

A copy of GLHA's process plan for developing the license application is attached as Appendix B to this SD1.

## 8.0 COMPREHENSIVE PLANS

Section 10(a)(2) of the FPA, 16 U.S.C. Section 803(a)(2)(A), requires the Commission to consider the extent to which a project is consistent with federal and state comprehensive plans for improving, developing, or conserving a waterway or waterways affected by a project. The staff has preliminarily identified and reviewed the plans listed below that may be relevant to the Projects. Agencies are requested to review this list and inform the Commission staff of any changes. If there are other comprehensive plans that should be considered for this list that are not on file with the Commission, or if there are more recent versions of the plans already listed, they can be filed for consideration with the Commission according to 18 CFR 2.19 of the Commission's regulations. Please follow the instructions for filing a plan at http://www.ferc.gov/industries/hydropower/gen-info/licensing/complan.pdf.

The following is a list of comprehensive plans currently on file with the Commission that may be relevant to the Projects:

Atlantic States Marine Fisheries Commission. 1999. Amendment 1 to the Interstate Fishery Management Plan for shad and river herring. (Report No. 35). April 1999.

Atlantic States Marine Fisheries Commission. 2000. Interstate Fishery Management Plan for American eel (*Anguilla rostrata*). (Report No. 36). April 2000.

Atlantic States Marine Fisheries Commission. 2000. Technical Addendum 1 to Amendment 1 of the Interstate Fishery Management Plan for shad and river herring. February 9, 2000.

Atlantic States Marine Fisheries Commission. 2008. Amendment 2 to the Interstate Fishery Management Plan for American eel. Arlington, Virginia. October 2008.

Atlantic States Marine Fisheries Commission. 2009. Amendment 2 to the Interstate Fishery Management Plan for shad and river herring. Arlington, Virginia. May 2009.

Atlantic States Marine Fisheries Commission. 2010. Amendment 3 to the Interstate Fishery Management Plan for shad and river herring, Arlington, Virginia. February 2010.

Atlantic States Marine Fisheries Commission. 2013. Amendment 3 to the Interstate Fishery Management Plan for American eel. Arlington, Virginia. August 2013.

Atlantic States Marine Fisheries Commission. 2014. Amendment 4 to the Interstate Fishery Management Plan for American eel. Arlington, Virginia. October 2014.

Maine Atlantic Sea-Run Salmon Commission. 1984. Strategic plan for management of Atlantic salmon in the State of Maine. Augusta, Maine. July 1984.

Maine Department of Agriculture, Conservation, & Forestry. Maine State Comprehensive Outdoor Recreation Plan (SCORP): 2014-2019. Augusta, Maine.

Maine Department of Conservation. 1982. Maine Rivers Study-final report. Augusta, Maine. May 1982.

Maine Department of Marine Resources. Maine Department of Inland Fisheries and Wildlife. 2008. Strategic Plan for the Restoration of Diadromous Fishes to the Penobscot River. Augusta, Maine. March 2008

Maine Department of Marine Resources. Maine Department of Inland Fisheries and Wildlife. 2008. Operational Plan for the Restoration of Diadromous Fishes to the Penobscot River. Augusta, Maine. July 2, 2009.

Maine State Planning Office. 1987. Maine Comprehensive Rivers Management Plan Vols 1-3. Augusta, Maine. May 1987.

Maine State Planning Office. 1992. Maine Comprehensive Rivers Management Plan. Volume 4. Augusta, Maine. December 1992.

National Marine Fisheries Service. 1998. Final Amendment #11 to the Northeast Multi-species Fishery Management Plan; Amendment #9 to the Atlantic sea scallop fishery Management Plan; Amendment #1 to the Atlantic salmon Fishery

Management Plan; and Components of the Proposed Atlantic herring Fishery Management Plan for Essential Fish Habitat. Volume 1. October 7, 1998.

National Marine Fisheries Service. 2018. Recovery Plan for the Gulf of Maine Distinct Population Segment of Atlantic Salmon. Hadley, Massachusetts. January 2019.

National Park Service. 1993. The Nationwide Rivers Inventory. Department of the Interior, Washington, D.C.

U.S. Fish and Wildlife Service. 1989. Atlantic salmon restoration in New England: Final environmental impact statement 1989-2021. Department of the Interior, Newton Corner, Massachusetts. May 1989.

U.S. Fish and Wildlife Service. n.d. Fisheries USA: the recreational fisheries policy of the U.S. Fish and Wildlife Service. Washington, D.C.

U.S. Fish and Wildlife Service. Canadian Wildlife Service. 1986. North American waterfowl management plan. Department of the Interior. Environment Canada. May 1986.

## 9.0 MAILING LISTS

The lists below, in this scoping document, are the Commission's official mailing lists for the Projects. If you want to receive future mailings for these proceedings and are not included in the lists below, please send your request by email to efiling@ferc.gov, or by mail to: Kimberly D. Bose, Secretary, Federal Energy Regulatory Commission, 888 First Street, N.E., Room 1A, Washington, DC 20426. Submissions sent via any other carrier must be addressed to: Kimberly D. Bose, Secretary, Federal Energy Regulatory Commission, 12225 Wilkins Avenue, Rockville, Maryland 20852. All written and emailed requests to be added to the mailing lists must clearly identify the following on the first page, as appropriate: **Ripogenus Hydroelectric Project (P-2572-133)** and/or **Penobscot Mills Hydroelectric Project (P-2458-247).** You may use the same method if requesting removal from the mailing lists below.

Register online at http://www.ferc.gov/docs-filing/esubscription.asp to be notified via email of new filings and issuances related to these Projects or other pending projects. For assistance, please contact FERC Online Support at Mailto:FERCOnlineSupport@ferc.gov, or toll free at 1-866-208-3676, or for TTY, (202) 502-8659.

**APPENDIX A**
**STUDY PLAN CRITERIA**
**18 CFR Section 5.9(b)**

Any information or study request must contain the following:

1. Describe the goals and objectives of each study proposal and the information to be obtained;

2. If applicable, explain the relevant resource management goals of the agencies or Indian tribes with jurisdiction over the resource to be studied;

3. If the requester is not a resource agency, explain any relevant public interest considerations in regard to the proposed study;

4. Describe existing information concerning the subject of the study proposal, and the need for additional information;

5. Explain any nexus between project operations and effects (direct, indirect, and/or cumulative) on the resource to be studied, and how the study results would inform the development of license requirements;

6. Explain how any proposed study methodology (including any preferred data collection and analysis techniques, or objectively quantified information, and a schedule including appropriate filed season(s) and the duration) is consistent with generally accepted practice in the scientific community or, as appropriate, considers relevant tribal values and knowledge; and

7. Describe considerations of level of effort and cost, as applicable, and why proposed alternative studies would not be sufficient to meet the stated information needs.

## APPENDIX B
## RIPOGENUS PROJECT AND PENOBSCOT MILLS PROJECT PROCESS PLAN AND SCHEDULE

Shaded milestones are unnecessary if there are no study disputes. If the due date falls on a weekend or holiday, the due date is the following business day. Early filings or issuances will not result in changes to these deadlines.

| Responsible Party | Pre-Filing Milestone | Date | FERC Regulation |

Stephen Condren, Boxborough, MA.
Iâ€™ve been fishing the West Branch of the Penobscot for 20 years, most during relatively high flows, greater than 2,400 cfs. During the past 2 years, following reduced snow cover and drought conditions, the flows have been lower at times, 1,700 to 2,200. Iâ€™ve seen large sections of river bottom exposed along the banks and noticed reduce insect activity. Anecdotal and without studies to back it up, but I believe the low flows and exposed river bottom areas have adversely impacted the aquatic lifeforms of the insects. Any relicensing should address minimum flows that ensure a healthy environment for all river life.

Room 1A
Washington DC 20426

Project: MHPC# 1049-21 FERC 2572-133 Ripogenus Hydro; FERC 2458-257 Penobscot Mills Hydro
Scoping Document

Town: Various, ME

Dear Secretary Bose:

I am writing in response to the FERC's "Scoping Document 1 for the Ripogenus Hydroelectric Project (P-2572-133) and Penobscot Mills Hydroelectric Project (P-2458-247)" which was received in our office on August 19, 2021.

In my opinion, the FERC's scoping document does not adequately address cultural resources including archaeological sites around the impoundment margin and any architectural resources within the impoundment area. We have previously commented that a Phase I and possibly subsequent archaeological studies are necessary to determine site presence/absence, effect on sites from erosion, and possible National Register eligibility.

Our office stands by our June 29, 2021 recommendations for architectural and archaeological surveys (see attachment).

Please contact Megan Rideout at (207) 287-2992 or megan.m.rideout@maine.gov if we can be of further assistance in this matter.

Sincerely,

Kirk F. Mohney

Project: MHPC #1049-21 Great Lakes Hydroelectric; Ripogenus FERC 2572; Penobscot Mills FERC 2458
NOI License Application

Town: Various, ME

Dear Ms. Russell:

In response to your recent request, I have reviewed the information received June 14, 2021 to initiate consultation on the above referenced project in accordance with Section 106 of the National Historic Preservation Act of 1966, as amended.

The area of potential effect as noted on page 5-252 is "defined as all lands and waters within the Project Boundary.... This includes the area where Project operations or Project-related recreation activities or other enhancements may cause changes in the character or use of historic properties." Based on this definition of the APE, it is unclear from the discussion in Section 5.10.2 as to whether the entire Project Boundary was surveyed for architectural resources during the prior re-licensing effort. If such a survey was not conducted, or if it needs to be updated to identify other properties that are now 50 years of age or older, the Commission recommends that the applicant undertake further studies to identify all properties in the APE that may be eligible for listing in the National Register of Historic Places.

An architectural survey is recommended to identify and record information on all resources within the area of potential effect (APE) that are at least 50 years old. Survey must be completed according to our "Revised Above Ground Cultural Resource Survey Manual Project Review Specific." All surveys must be submitted electronically via our on-line CARMA database. See our website for more information: https://www.maine.gov/mhpc/quick-links/forms-instructions

A list of historic preservation consultants who are qualified to conduct architectural survey and have been trained in the use of the CARMA database may be found at the following page of our website: https://www.maine.gov/mhpc/programs/survey/approved-consultants/carma-trained-consultants

The archaeological resources section of the PAD (pp. 5-254 through 5-268 for Ripogenus and 5-265 through 5-268 for Penobscot Mills) accurately summarized archaeological mitigation work to date on the sites listed in the HPMP for the October 1996 license. No further Phase I or Phase II archaeological survey is necessary. Mitigation archaeological work not yet completed for the 1996 license should be brought forward for an HPMP for the 2026 license. Continued analysis and reporting on excavated sites (e.g. p5-261 and 5/262) should be a priority. Attempts to access the sites that have been difficult to access because of water levels or landowner permissions should continue.

After the 1996 license, a major archaeological collection (the Dan Hurld collection) primarily from the Penobscot Mills project area was acquired by the Maine State Museum. This collection consists of over 1000

stone tools and several hundred pieces of Native American ceramics, recovered during periods of low water on the Penobscot Mills lakes by Dan Hurld between about 1930 and 1955. The artifacts are marked by site location and can be attributed to specific archaeological sites by site number. This collection will provide a major increase in cultural context (age of occupation, types of artifacts at each site) when combined with existing information from the Phase I, II and mitigation work. We request that a professional analysis of the Dan Hurld collection, and integration of the information contained within it to the known site information be undertaken and funded as part of the HPMP for the 2026 license, or as work in advance of license issuance. This is appropriate mitigation for the effects of the raised water levels on the Penobscot Mills impoundments on scores of archaeological sites around the impoundment.

If you have any questions regarding archaeology, please contact Dr. Arthur Spiess of this office at Arthur.Spiess@maine.gov.

Please contact Megan M. Rideout of our staff at 287-2992 or megan.m.rideout@maine.gov if you have any questions regarding above ground resources.

Sincerely,

Kirk F. Mohney

Kirk F. Mohney
State Historic Preservation Officer

Amanda Swanberg, Damariscotta, ME.
The Restorative Justice Institute of Maine (RJIM) supports the Penobscot Nation in their efforts to be reinstated as the rightful stewards of the West Branch of the Penobscot River. We acknowledge the Penobscot Nation as a sovereign nation which should have the rights to manage land, water, and fisheries resources on their native lands. We agree with the Penobscot Nation’s assessment that the West Branch ecosystem is adversely impacted by dams now owned by Brookfield and that decommissioning and removal is the only way to begin to restore the health of the river. We trust the Penobscot Nation to be stewards of this waterway for the benefit of their people, the people of Maine, and the ecosystems that depend on it. We believe transferring the rights of the river back to the Penobscot Nation is a necessary step in the decolonization of Maine’s natural resources. It is RJIM's mission to work with individuals and communities to promote community healing, and that healing past harms that have happened to the land and water is directly connected to this collective healing.

Ripogenus Hydroelectric Project and
Penobscot Mills Hydroelectric Project
Great Lakes Hydro America, LLC

Project Nos: 2572-133, 2458-247

Thursday, September 9, 2021

SCOPING SESSION - TELECONFERENCE

Thursday, September 9, 2021

The Virtual Scoping Meeting, pursuant to notice, convened at 6:30 p.m.

P R O C E E D I N G S

6:30 p.m.

OPERATOR: Welcome and thank you for standing by. All participants will be in listen only, and I'm going to pass to Mr. Allan Creamer of FERC.

MR. CREAMER: Thank you very much. I apologize for the delay here. We just had some technical difficulties getting everything up and running. But welcome everyone to the Federal Energy Regulatory Commission's Virtual Scoping Meeting to for the Ripogenus Hydroelectric Project Number 2572, and the Penobscot Mills Hydroelectric Project Number 2458.

My name is Allan Kramer and I work in the Office of Energy Projects Division of Hydropower Licensing at FERC. And I am the project coordinator for these proceedings. Several other FERC staff are joining me today along with representatives of Great Lakes Hydro America, these folks are available to listen to you as you provide comments during our scoping session.

The purpose of scoping is to seek input on the specific concerns or environmental issues related to relicensing the projects, and to identify all projects that should be considered in our environmental document. And we'll begin by going over important meeting notes, and will continue with a short introductory to the licensing process

and schedule.

Great Lakes Hydro America will then provide a FERC presentation on the projects and their operation. Following Great Lakes Hydro America's presentation we will begin taking your comments. As we all know these virtual meetings are not routine for the Commission. It is in fact the first instance for hydro licensing. I thank everyone now for your patience while others are being heard.

As a point of clarification there will be no summary at the end of our meeting. You are finished after providing your comments, and you will be disconnected from the call. For those of you wishing to speak we have a Court Reporter in each of our virtual breakout rooms to transcript this evening's meeting.

This transcript will serve as part of the Commission's record in these proceedings. When prompted we ask that you please state and spell your name clearly, and provide information on any affiliation or group for which you are speaking before commenting.

After Commission staff's introduction to the licensing process and Great Lakes Hydro America's introductory to the project, you will be invited to the breakout rooms in the order we received your call. Please remain on hold until it is your turn to speak at which time you will be provided with five minutes. At the end of your

time the operator will disconnect you, and then we'll move to the next in line based on the order in which we were called in.

While during these meetings you cannot listen to other commentors as is typical in normal times at a scoping. I reminder you that a transcript of this scoping meeting will be placed on the Commission's website and E-Library. In advance, I want to advise the organizers of the call as well as Court Reporters that there may be times that we have no callers, and that is to be expected. However, we will keep the call open for the general public the entire duration of the meeting.

If you prefer not to speak today, wish to file comments for any other reasons, or if you have technical difficulties during the call, you can file written comments with the Commission by October 9, 2021. Instructions for filing written comments are on page 2, Paragraph O of our office sent 2021 notice. We encourage you to e-file your written comments.

For those of you who wish to be on FERC's official mailing list, please see the instructions on page 34 of our scoping document 1 also issued on August 10, 2021. Finally, we recommend that you go to FERC's website at www.FERC.gov and e-subscribe to the projects using Project Number E-2572 and/or E-2458 which are the project numbers

for the Ripogenus Project 2572, and the Penobscot Mills Project 2458.

During this you are notified of any filings with the Commission, or of any issuances by the Commission related to these projects. I'll now switch gears and introduce the licensing process and the schedule, and will then turn it over to Great Lakes Hydro for its introductions to the project.

Great Lakes Hydro America has chosen to relicense the Ripogenus and Penobscot Mills projects using the integrated licensing process, or ILP. The ILP is the Commission's default licensing process. The process is driven by process plans with defined timelines and deadlines for all participants, including Commission staff.

The first step in the process is the development of a preliminary application document which is prepared by the applicant after gathering information from resource agencies and other sources. The process is marked by early scoping as well as study plan development and resolution as any study disagreement.

The city criteria are used to develop focused and appropriate studies and a Commission approved study plan is developed in consultation with the stakeholders -- the specific criteria represented in Appendix A of scoping document one. There are two years of study which gives us

an opportunity to review study results and make adjustments to the study plan based on specific criteria.

Towards the end of the prefiling process the applicant is required to develop a preliminary licensing proposal, or draft license application that includes his proposal for relicensing the project. The process is defined to integrate stakeholder processes such as Commission's licensing process, the Maine Department of Environmental Protections, water quality certification process, consultation under the Endangered Species Act, and the federal agency inspection 18 prescription process, thereby improving the overall efficiency of the licensing process.

But where are we in the relicensing process with the Ripogenus and Penobscot Mills? The relicensing process begins with an applicant filing its notice of intent in a preliminary application document. Great Lakes Hydro America filed these documents on June 11, 2021.

Commission staff issued a scoping document one for the project, and the Commission issued a public notice for the proceeding on August 10, 2021. Commission staff is holding virtual public scoping meetings, and Great Lakes Hydro America is conducting a virtual environmental site scoping process today, September 9, 2021.

Stakeholders then have an opportunity to file

comments on this project on a preliminary application process, as well as file study requests by October 9, 2021. Once the comment periods ends Great Lakes Hydro America will prepare a proposed study plan which is due on November 23, 2021.

There will be a meeting to discuss the proposed study plan on or around December 23, 2021. This represents an informal opportunity to resolve this agreement with studies. Comments on the preferred study plan are due by February 21, 2022, after which Great Lakes Hydro America will file a revised study plan.

The Commission will issue its study plan determination by April 22, 2022. If necessary there has been a formal dispute resolution process that follows issuance of the study plan determination. The ILP provides for two years of studies which for these projects occur in 2022 and 2023. Great Lakes Hydro America will file an initial study report by April 21, 2023, and a final study report by April 21, 2024.

Meetings will be held for each report. Great Lakes Hydro America will then file a preliminary licensing proposal or, PLP, by May 3, 2024. Stakeholder comments on the PLP are due by August 1, 2024. The refiling part of the process wraps up the Great Lakes Hydro America's filings. License application must be filed by September 30, 2024.

I know I have gone through a lot of information in a short period of time. What I presented is intended to be an overview of the process and the schedule. The details can be found in Appendix B of scoping document one. Also, as you can see, this is a fast-moving process, especially in the first 10 months, and it is a process that provides for stakeholder involvement throughout.

At this point I'm going to turn the meeting over to representatives from Great Lakes Hydro America for a short introduction to the projects.

MR. DORMAN: Thank you Allan. Good evening everyone. Thank you for dialing in tonight. My name is Randall Dorman for GLHA, and I'll be in charge of leading the relicensing of the west branch projects, Penobscot Mills and Ripogenus license projects.

I'm going to provide a very brief overview of these two projects, but it's worth noting that they are very large, and they're very complex, and so it's going to be hard to convey all of the relationship between these components over the phone.

And so I strongly urge anyone who hasn't had the opportunity to take a look at our preapplication document. Allan eluded to this in his introduction. This was something we had filed back on June 11. It's available on FERC's website. And what this document does is it gives an

overview of our project facilities, our project operations, and it summarizes everything we could find on resources associated with the project.

So anything affected by the project is summarized in the reapplication document. We tried very hard to provide as clear an through a description of our project facilities and operations, and I'm hoping that when you get a chance to take a look at it it's a helpful guide for you.

So with that said on to the description of the project. These facilities are licensed under two separate FERC licenses, so we have Ripogenus which is licensed in Project Number 2572, and then we have Penobscot Mills which is licensed as Project 2458. And although they are separate licenses and will file separate license applications for them, they both have the same expiration dates.

They are right above each other on the west branch, and so we elected to relicense them essentially as a single unit in order to pick up some efficiencies and reduce paperwork and the amount of meetings. So that was why we've chosen to do this the way we have.

So what I will do now is I'm just going to walk through a very high level overview of the project. I'm going to stop at the top of our system and I'm going to work down through each of the facilities and so we'll start with the Ripogenus Project, and we have one kind of interesting

development which is part of the project. It is a wetlands mitigation project that came out of the last licensing, but it's not a functioning working reservoir, so we aren't manipulating flows up there to affect the project.

The water is just flowing out of that naturally run of river because it's like I said, it's a run of river mitigation project that we had established. But water runs down from the Misoukis [ph] into the Ripogenus impoundment. And the Ripogenus impoundment has several sub-bases within it that are part of that larger impounded, you have Ambajejus Lake, you have Caribou Lake, you have Chesuncook Lake, you have Blue Span, Brandy Pond, and Black Pond, all of these are part of that Ripogenus impoundment which is created by the Ripogenus span.

There are no generating facilities at the dam itself. Water is diverted down to the McKay Station, which is the generating station associated with Ripogenus. So McKay is a 37.5 megawatt generating facility. Water goes into McKay, it's dispersed back into the west branch, and then that is largely the end of project's features associated with the Ripogenus. If you saw a map you could see the footprint of it.

You can look at the size, it's pretty enormous. We've got almost 30,000 acres of impoundments. But it's primarily those two facilities, Ripogenus and McKay Station.

There is a very long transmission line that is part of the project, but in terms of river frontage really we don't go much below McKay Station as part of Ripogenus.

So that's it for that project. And now I'll talk a little bit about the Penobscot Mill Project which is much more complicated because it has many more moving pieces so to speak. So I'll start at the top of Penobscot Mills Project with the North Twin impoundment. And again the North Twin impoundment like Ripogenus is composed of these separate sub-basins that are part of that.

North Twin includes Elbow Lake, North Twin Lake, South Twin Lake, Pemadumcook Lake, and the Ambajejus Lake. So water from McKay goes down the west branch, to reach these North Twin impoundments. We also have as part of this system Millinocket Lake which we can pump water from into North Twin if we need augment flows.

From North Twin water then flows to North Twin generating station, that's a 6.9 megawatt facility. Water from North Twin is then cast down into Millinocket Lake, and again Millinocket consists of Quakish Lake and Ferguson Pond. And at Millinocket Lake we have two components there. We have Stone Dam, and then we have Millinocket Station. So most of the water is diverted by a stone dam into Millinocket Station, that's a 37.4 megawatt station.

From Millinocket it arches back downstream,

enters that pond which is actually outside of the project boundary. That pond the water travels to Dolby impoundment, and from Dolby the water runs through Dolby Station a, 16.5 megawatt station, pass from Dolby back into the west branch, follows the river down to the East Millinocket impoundment. This is our smallest impoundment in this system.

And then from East Millinocket goes to East Millinocket Station, which is a 7 megawatt station, and then from there goes back into the west branch, and that's the bottom of our project. So there are some very helpful illustrations, some maps, all of the maps of these projects in that pad, as well as a very handy diagram.

I'm not going to kid you I'm looking at this diagram as I'm going through this description. This facility, it very clearly lays out where the water is going. It also has specific details on how much water and when some of these operating requirements we have are in place. So again, I'll make my last pitch for the preapplication document here, because I just really think it will be a useful reference document for you to look at.

And with that Allan, I think that concludes my overview of the project there.

MR. CREAMER: Thank you Randy. That's it Julie, we are ready to begin our comments.

OPERATOR: Thank you. One moment.

(Plays recording.) Written comments are given equal consideration.

We will go ahead and place you in your break-out rooms. Just to confirm where did Steve go?

UNIDENTIFIED SPEAKER: Steven, place him over in Room 1.

OPERATOR: Room 1, okay. All right.

MADDISON: My name is Maddison and I'll be recording your break out room today. Just let me know when everybody is ready to speak to our first person.

MR. GIBSON: Yes good evening, this is Jim Gibson. Also here, this is Kevin Bernier.

MS. BLY: And Wendy Bly with Quantra Associates, I'm good.

MS. PHILIP: Christine Philip with FERC, I'm good.

MR. TERHAAR: Monte with FERC I'm good.

OPERATOR: Okay perfect. Okay thank you. I will be giving the -- there for spelling correct, they won't be doing this --

We're waiting for them to spell it themselves, spell it and announce themselves.

UNIDENTIFIED SPEAKER: I think that's brilliant. A question for the Court Reporter. Is there a preference there?

REPORTER: I'm sorry would you say that again?

OPERATOR: Yes would you like us to -- the operator, would you like me to acknowledge and spell the name for each person, or would you prefer them to announce and spell their own name?

REPORTER: Sure if you can like saying the next speaker, the name and if you spell it out that would be nice if you can.

OPERATOR: Okay perfect, thank you.

REPORTER: You're welcome.

OPERATOR: Our first participant is Sarah, S-A-R-A-H, S-I-N-G-O. Hello, and thank you for participating. You are now in the room to provide your comments to the Court Reporter. You will have five minutes to speak. I will give you a warning when you have 30 seconds remaining. You may begin, thank you.

And it looks like we have Sarah disconnected, so Sarah is no longer with us. Ms. Singo is no longer in the room. I will let you know when we have another person in the room.

REPORTER: Okay.

OPERATOR: Thank you.

We have Angela Reed, A-N-G-E-L-A R-E-E-D. Hello, you are now in the room to provide your comments to the Court Reporter. you will have five minutes

to speak. I will give you a warning when you have 30 seconds remaining. Please state and spell your name for the record, and state if you are on behalf of a group of an affiliation. You may begin.

MS. REED: Hello Thank you for taking my comments. My name is Angela Reed, A-N-G-E-L-A R-E-E-D. I am just representing myself as a private citizen. My first comment is I know that you guys have to do this virtually, but it seems like with the technology today we could have had an ability to see documents online, have some kind of visual component as well as maybe an question an answer session.

The second thing is I'm wondering if there will be studies done. I think there needs to be studies done on the reliability of options of getting better fish passage at the very least on these projects, and whether we still need these projects. Do we need to still have dams given the increase in other renewable power projects that there are coming up throughout the world, but certainly also in Maine?

I think that we need to not be forsaking the entire west branch. It seems like the Penobscot River is somewhat of a misleading thing to say nowadays, but that these dams it ends up being a very long chain of lakes thrown together by some stone, -- and water. That is not a natural river eco-system, it's scarily managed, and does not

represent at all what organisms or people evolved with for thousands of years on this continent prior to the impoundments.

So it is my sincere desire that we do both some ecological analysis of both getting better fish passes released again, as the Commission stands, but also not only ecological, but financial analysis of how much hydropower do these -- how much power, excuse me, do these contribute to the overall scenario, and what would happen if we didn't have them? What would the result be?

I think the history of this is Penobscot Mills is obviously very different in this day and age. It needs to be considering that people are coming here to recreate, and more so nowadays, and that may be extra benefitted by not having as many of these kinds of dams in the area as there are, but I think we need to do some kind of analysis on what are the options, and really you guys need to do a better job of getting the word out to the public, and putting it in a more understandable way, and allowing people to ask questions and give more opportunity for people to really understand the impacts that are such a huge component of when you really talk about for Maine, the way life should be, and vacation land.

I think we need to really give people an honest perspective on what happens to the "natural resources" of

the state, and how we are going to protect them for the future. I'm done. I know I probably haven't taken up my five minutes, but I think I'm done.

FERC: Thank you for your comments. We will include your comments in the public record for this project. And they will be considered in the review for this project. You may now end the call.

MS. REED: Okay thanks.

OPERATOR: Okay perfect. And I will let you know when our next participant is in here.

MR. PAONE: Yes I am here.

OPERATOR: Our next participant is Charles Paone. C-H-A-R-L-E-S P-A-O-N-E. Hello, and thank you for participating. You are now in the room to provide your comments to the Court Reporter. You will have five minutes to speak. I will give you a warning when you have 30 seconds remaining. Please state whether you are speaking on behalf of a group, or affiliation when you begin your comments. Thank you. You may begin.

MR. PAONE: Yes. My name is Charles Paone, and I am making these comments as a property owner on Caribou Lake. A review of this filing raises concerns regarding the impact, the annual drawdown of Ripogenus impoundment has on the water levels with Caribou Lake.

By early to mid-summer Caribou Lake often

experiences a significant reduction in water levels, even beyond the last two drought years. This reduction in water level and exposures of the lake beds make it very difficult for access to the lake from the many houses located on it.

Further, with such low-levels of water navigation has become very hazardous, and access to Chesuncook and Ripogenus Lakes from Caribou Lake is almost impossible, and likely to be impossible by the end of this month. The Caribou boat launch is frequently made useless due to the law water levels in the summer.

The preapplication document states that the full pond elevation during normal times is 941.6 feet. It further states during normal operation in normal in-flow years, the Ripogenus impoundment elevation is held relatively stable at 941.6 feet during summer months, and is gradually drawn down in the fall with a target low elevation of 913.6 feet by late winter in anticipation of the spring thaw and high flows.

I have been on Caribou Lake since 1968, and it frequently seems significant reductions of water and increases in the lake bed exposure during summer months often in excess of 50 to 60 feet. In paragraph 3.1.4 proposed environmental measures, GLHA proposes to continue to operate and maintain certain environmental measures.

These measures include certain recreational

resources such as white water boat flows operate and maintain 11 recreational sites. A commitment to continue to collect recreational use information during -- I'm sorry, use information every six years. However, none of these measures addresses adequate water levels at Caribou Lake, and the impact it has on the recreational use of the landowners and homeowners on Caribou Lake, all of whom have made a significant financial commitment to the area.

Since this license would establish the criteria for operation for the next 50 years, and given the obvious rapidly changing climate conditions that we have documented, or have been documented and well-established by many governmental agencies throughout the world, including NOAA, there needs to be a periodic review process to ensure that the critical assumptions -- I emphasize the critical assumptions used in developing the water usage criteria reflect today's environment and are adjusted in the future as necessary to reflect changing environmental conditions.

Assumptions such as normal water level in the impoundment, and normal inflows need to be continually monitored in order to determine what the appropriate outflow requirements should be. Certainly it is unrealistic to assume the water level requirements that were established some time ago will continue to be appropriate in the next 50 years, given the serious climate changes we are all

experiencing.

It would be helpful to better understand these issues if the following information could be provided. Number one, in what year was the normal full pond elevation of Ripogenus impoundment of 941.6 feet established? Number two, in paragraph 3.1.3 it is stated that Ripogenus impoundment elevation is held relatively stable at 941.6 feet during the summer months, and it's gradually drawn down starting in the fall.

OPERATOR: Excuse me, you do have 30 seconds left.

MR. PAONE: A review of studies and/or data for the last 10 years for the Ripogenus impoundment showing the actual normal elevation at the start of the summer per year, the actual elevation starting at the beginning of the fall per year, the actual maximum draw down per year, the actual low elevation by late winter per year.

Number three, is there any data for Caribou Lake regarding water levels, recreational impacts, or navigational issues.

OPERATOR: And excuse me, that is your five minutes.

MR. PAONE: Thank you.

FERC: Thank you for your comments, we will include your comments in the public record for this project,

and they will be considered in the review of the project. You may now end your call.

MR. PAONE: Thank you.

OPERATOR: Next we have Clayton Cole. C-L-A-Y-T-O-N C-O-L-E. Hello, and thank you for participating. You are now in the room to provide your comments to the Court Reporter. You will have five minutes to speak. I will give you a warning when you have 30 seconds remaining. Please state whether you are speaking on behalf of a group, or affiliation and then begin your comments. You may begin, thank you.

MR. COLE: I am here representing the Penobscot River Traveling Trail. We are an organization that has created a series of campsites starting in Midway every 10 miles to Tidewater into Bucksport and even beyond. Our campsites are available at no charge for river travels in paddled, manually propelled watercraft.

I have an interest in this relicensing process as it seems that it would affect how our paddling trail will work. We are concerned about river sustainability with respect to the Penobscot Nation. Also with managing regular close or river travel, and especially with wildlife and fish life.

I don't have a strongly held opinion at this time, but am very concerned about how the process will play

out. For now that is my comment.

FERC: Thank you for you comments. We will include your comments in the public record for this project, and they will be considered in the review for the project. You may now end the call. Thank you.

MS. BLY: This Wendy Bly. Is anybody else still in this meeting room?

MR. GIBSON: Yeah Wendy this is Jim.

MS. BLY: Okay just checking.

OPERATOR: And this is the operator. We currently don't have anybody dialed in to make comments, so I will let you know when we have somebody join in, but you'll hear the tone when they join as well, but currently we just don't have anybody dialed in. Thank you.

MR. GIBSON: And I get the impression the other room is the same way right now. I received a similar message from Kate.

MS. BLY: Yep. They're exactly the same. Everybody comes into like a main room, and then the main operator Julie, she divvies them up between the two rooms, so there's nobody dialed in at all currently. We're both kind of at a standstill.

MR. GIBSON: Thank you.

MS. BLY: You're welcome.

MR. GIBSON: While we have a moment is it

possible to read off the names again of the three speakers so far?

MS. BLY: Yes. We did have Sarah Singo, but they disconnected, that was the very first one. Our first one who actually spoke was Angela Reed.

MR. GIBSON: Okay.

MS. BLY: And then our next one was Charles Paone.

MR. GIBSON: Okay yep.

MS. BLY: And then our last one that just spoke was Clayton Cole.

MR. GIBSON: Thank you very much.

MS. BLY: You're very welcome.

OPERATOR: Next we have Stephen Bishop. S-T-E-P-H-E-N B-I-S-H-O-P. Hello, and thank you for participating. You are now in the room to provide your comments to the Court Reporter. You will have five minutes to speak. I will give you a warning when you have 30 seconds remaining. Please state whether you're speaking on behalf of a group or affiliation, then begin your comments. You may begin. Thank you.

MR. BISHOP: Thank you very much. Hi. Again my name is Stephen Bishop. I'm actually the President of the Penobscot Lot Owners Association, so I do have property on Ambajejus Lake, and I work with a lot of the Association,

with other people who have lots on Lake Ambajejus.

I am aware of the current process underway for reapplying for a license for Ripogenus Dam and other projects in 2024. I would just like to say I support the relicensing of the dams for the following reasons. While the dams generate electricity from Brookfield to sell, they also control water levels on the west branch in the connecting lakes.

Many people live on the lakes both in-season and year around. Many people make their living working on the lakes and rivers, rafters, flying service, main guides, game wardens, campgrounds, restaurants, and general stores to name a few. Additionally, many people who have live in Millinocket, East Millinocket and Midway work hard to make a living and support their families in jobs connected to the tourist industry supported by the local watershed.

These are the same people who lost their jobs when the mills closet. Would there be a consideration to decommission any of the dams along this watershed, or shut down any of these associated projects, I hope there's a study undertaken that examines the impact a closure will have on the livelihoods of people who depend on the watershed for their livelihood. Thank you very much.

OPERATOR: Thank you for your comments. We will include your comments in the public record for this project,

and they will be considered in the review of the project. You may now end your call. Thank you.

MR. BISHOP: All right thank you very much.

OPERATOR: And we don't have anybody else dialed in currently, sorry. He went through the prompts super quickly, so he came through, but currently we don't have anybody else, and I will let you know when we have somebody else dial in.

OPERATOR: Just to let you know we do have somebody dialed in. I'm pretty sure they will go to room one since we got the last person, but just to let you know.

OPERATOR: Next we have Ed Spear, E-D S-P-E-A-R. Hello, and thank you for participating. You are now in the room to provide your comments to the Court Reporter. You have five minutes to speak. I will give you a warning when you have 30 seconds remaining. Please state whether you're speaking on behalf of a group or affiliation and then begin your comment. You may begin, thank you.

MR. SPEAR: Good evening. My name is Ed Spear and I'm not affiliated. I was a biologist with -- internet interference Great Northern Paper and I went to work on the west branch in 1977 and concluded when Brookfield Green Lakes Hydro, a licensee took over. I was retiring.

I think my comments should be considered expert testimony, and I intend to eventually submit some written

comments. So we'll start with one general comment. The scoping document basically talks about how good things are, and I would like to remind FERC that when they issued the license back in 1996, they talked about how good everything was, including the salmon fishing.

And nothing can be farther from the truth. We looked right to the top location in 1992, and onto the town the EIS and the FEIS license was issued, it was then Great Northern Paper Company, and the river operated at I believe the EIS says relatively stable mode, and things would change.

Brookfield, Great Lakes Hydro, the licensee has gone into a peaking mode, and the results have been disastrous for the fish and the aquatic communities. The salmon fishing in the west branch lower McKay is generally now compressed to about a mile, a mile and half.

The salmon fishing flow, not Twin Dam, and the middle one, the Grinder one, I think it's now Mill one, Millinocket mill or something, has disappeared. And those are very likely results of the peaking operation. Peaking, and the literature was replete with this, is very, very tough on the fish and devastating on the aquatic communities, so.

I believe that if you look in the big A application and possibly in the -- application, you'll find

when Norman Go did a survey of macroinvertebrates and those studies are easily duplicated, that I'd like to also mention that Article 406 of the license talks about the whole brook side show, and the whole goal there was to provide -- try basically, and mostly try, and it was identified as a limiting factor that he took and with the present operation including today, even though I did move up, 1,000 or 100 depending how you take it.

Port workers basically do audits. Article 406 is moot. The evidence and the ramifications of peeking on juvenile salmon up and down the river is also especially in the Fry kind of damming, so those are the matrix you should really look into.

We should go back now and talk about what was formally called the rule tariff, which you might possibly call the Lake Water Management Plan, and as near as I can make out, there's no more water management plan. The water management plan is a time series of target zones for elevation in Rip Lake, and to some degree, a lesser degree in the Twin impoundment where you insure that you wouldn't run out of water in the winter, and at the rate we're going now there will be no water to meet any goals this winter.

So something has to be done to ensure that there's flows to meet environmental needs all the way through April 1, April 15. Some sort of water management

plan. People out west in the hydro projects stay out there, revisiting their water use plans. That can be a lot of different things.

So anyhow, the other thing which I would like to bring up is when I read the license. It seems to infer that someone is supposed to keep count of how power lake elevation generation. I'm sure that's happening.

OPERATOR: You do have 30 seconds left.

MR. SPEAR: Okay. I believe the slow data is on a computer somewhere but in an era of transparency, it's like looking for a black hole. FERC really needs to make the flow elevation -- the hourly flow and elevations for all the impoundments available to the public, and I'll let you go at that. I'll submit my written comments eventually, and thank you very much for your patience and good luck with what will surely be a long process.

OPERATOR: Thank you for your comments. We will include your comments in the public record for this project, and they will be considered in the review of the project.

MR. SPEAR: Thank you.

OPERATOR: You may now end the call thank you.

(Whereupon the meeting concluded at 8:41 p.m.)

CERTIFICATE OF OFFICIAL REPORTER

This is to certify that the attached proceeding before the FEDERAL ENERGY REGULATORY COMMISSION in the Matter of:

Name of Proceeding:
Ripogenus Hydroelectric Project and
Penobscot Mills Hydroelectric Project
Great Lakes Hydro America, LLC

Docket No.: Project Nos: 2572-133, 2458-247
Place: Virtual
Date: Thursday, September 9, 2021

were held as herein appears, and that this is the original transcript thereof for the file of the Federal Energy Regulatory Commission, and is a full correct transcription of the proceedings.

Virtual Scoping Meeting

Ripogenus Hydroelectric Project and

Penobscot Mills Hydroelectric Project

Great Lakes Hydro America, LLC

Project Nos: 2572-133, 2458-247

SCOPING SESSION - TELECONFERENCE

Thursday, September 9, 2021

The Virtual Scoping Meeting, pursuant to notice, convened at 6:30 p.m.

P R O C E E D I N G S

OPERATOR: Welcome, and thank you for standing by. All participants will be able to listen-only.

I would now like to turn your conference over to Mr. Allan Creamer. Sir, you may begin.

MR. CREAMER: Thank you very much.

I apologize for this delay here, we've had some technical difficulties getting going this morning.

Welcome, everyone to the Federal Energy Regulatory Commission's Virtual Scoping Meeting for the relicensing of the Ripogenus Hydroelectric Project, No. 2572, and the Penobscot Mills Hydroelectric Project, No. 2458.

My name is Allan Creamer, and I work in the Office of Energy Projects, Division of Hydropower Licensing at FERC, and I am the project coordinator for these proceedings. Several other FERC staff are joining me today, along with representatives of Great Lakes Hydro America and Brookfield Renewable, will listen to you as you provide comments during our scoping session.

The purpose of scoping is to seek input on the specific concerns or environmental issues related to relicensing the projects and to identify alternatives that should be considered in our environmental document.

I will begin by going over important meeting

notes, and will continue with a short introduction to the licensing process and schedule. Great Lakes Hydro America will then provide a short presentation on the projects and their operation.

Following Great Lakes Hydro America's presentation, we will begin taking your comments. As we all know, these virtual meetings are not routine for the Commission; it is in fact the first instance for hydro licensing. I thank everyone now for your patience while others are being heard.

As a point of clarification, there will be no summary at the end of our meeting. You are finished after providing comments; you will be disconnected from the call.

For those of you wishing to speak, we have a court reporter in each of our virtual breakout rooms to transcribe this evening's meeting. This transcript will serve as part of the Commission's record in these proceedings. When prompted, we ask that you please state and spell your name clearly, and provide information on any affiliation or group for which you are speaking or commenting.

After Commission Staff's introduction to the licensing process and Great Lakes Hydro America's introduction to the project, you will be invited to breakout rooms in the order in which we received your call. Please

remain on hold until it is your turn to speak; at which time you will be provided with five minutes. At the end of your time the operator will disconnect you and will move to the next in line, based on the order in which you had called in.

During these meetings you cannot listen to other commenters, as is typical in scoping. I remind you that a transcript of the scoping meeting will be placed on the Commission's website in eLibrary.

In advance, advisors that organizes this call, tell the court reporter that there may be times that we have no callers, and that is to be expected. However, we will keep the call open for the general public the entire duration of the meeting.

If you prefer not to speak today, or wish to file comments for any other reason, or if you have technical difficulties during the call, you can file written comments with the Commission by October 9th, 2021. Instructions for filing written comments are on page 2, paragraph O of our August 10, 2021 notice. We encourage you to eFile your written comments.

For those of you who wish to be on the FERC mailing list, official mailing list, please see the instructions on page 34 of our Scoping Document 1, also issued on August 10th, 2021.

Finally, we recommend that you go to FERC's

website, at www.ferc.gov and eSubscribe to the project using Project Nos. P-2572 and/or P-2458, which are the project numbers for the Ripogenus Project, 2572, and the Penobscot Mills Project, 2458. Doing this will ensure that you are notified of any filings with the Commission or of any issuances by the Commission related to these projects.

I'll now switch gears and introduce the licensing process and our schedule, and we'll then turn it over to Great Lakes Hydro for its introduction to the projects.

Great Lakes Hydro America has chosen to relicense the Ripogenus and Penobscot Mills Projects using the Integrated Licensing Process, or ILP. The ILP is the Commission's default licensing process. The process is driven by a process plan with defined timelines and deadlines for all participants, including Commission staff. The first step in the process is development of a Preliminary Application Document which is prepared by the applicant after gathering information from resource agencies and other sources.

The process is marked by early scoping as well as study plan development and resolution of any study disagreements. Specific criteria are used to develop focus and appropriate studies, and a Commission-approved study plan is developed in consultation with the stakeholders. The specific criteria are presented in Appendix A of Scoping

Document 1.

There are two years for studies, so there is an opportunity to reduce study results and make adjustments to the study plan based on specific criteria. Towards the end of the prefiling process, the applicant is required to develop a preliminary licensing proposal, or draft license application that includes a proposal for relicensing the project.

The process is designed to integrate stakeholder processes such as the Commission's licensing process, the Maine Department of Environmental Protection's water quality certification process, consultation under the Endangered Species Act, and the Federal agencies Section 18 process. Thereby improving the overall efficiency of the licensing process.

So where are we in the relicensing process for Ripogenus and Penobscot Mills? The relicensing process begins with an applicant filing a Notice of Intent and a Preliminary Application Document. Great Lakes Hydro America filed these documents on June 11, 2021. Commission Staff issued its Scoping Document 1 for the projects, and the Commission issued a public notice to proceed on August 10th, 2021.

Commission Staff is holding virtual public scoping meetings, and Great Lakes Hydro America conducted a

virtual environmental site review of the project today, September 9th, 2021.

Stakeholders then have an opportunity to file comments on Scoping Document 1 and the Preliminary Application Document as well as file study requests by October 9th, 2021. Once the comment period ends, Great Lakes Hydro America will prepare a proposed study plan which is due by November 23rd, 2021. There will be a meeting to discuss the proposed study plan on or around December 23rd, 2021. This represents an informal opportunity to resolve disagreements with the studies.

Comments on the proposed study plan are due by February 21st, 2022. After which Great Lakes Hydro America will file a revised study plan. The Commission will issue a study plan determination by April 22nd, 2022.

If necessary, there is a formal dispute resolution process that follows issuance of the study plan determination. The ILP process provides for two years of studies, which for these projects occur in 2022 and 2023. Great Lakes Hydro America will file an initial study report by April 21st, 2023 and a final study report by April 21st, 2024. Meetings will be held for each report. Great Lakes Hydro America will then file a Preliminary Licensing Proposal, or PLP, by May 3rd, 2024. Stakeholder comments on the PLP are due by August 1st, 2024.

The prefiling part of the process, Great Lakes Hydro America filing license applications for the two projects by September 30th, 2024.

I know I've gone through a lot of information in a short period of time. What I presented was intended to be an overview of the process schedule. The details can be found in Appendix D of Scoping Document 1.

Also, as you can see, this is a fast process, especially in the first eight to ten months, and it is a process to provide for stakeholder involvement.

At this point I'm going to turn the meeting over to a representative of Great Lakes Hydro America for an introduction to the projects and their operations.

MR. DORMAN: Thank you, Allan. Good morning, everyone. Thank you for dialing in tonight. My name is Randall Dorman, I'm the Licensing Manager for GLAJ, and I'll be managing the relicensing of the two West Branch projects, Penobscot Mills and Ripogenus license project.

I'm going to provide a very brief overview of these two projects; but it's worth noting that they are very large and they're very complex; and so it's going to be hard to convey all of the relationships between these components over the phone.

And so I'd strongly urge anyone who hasn't had the opportunity to take a look at our Pre-Application

document. Allan alluded to this in his introduction as something we had filed back on June 11th. It's available on FERC's website.

And what this document does, it gives an overview of our project facilities, our project operations, and it summarizes everything we could find on resources associated with the projects. So anything affected by this project is summarized in that Pre-Application Document.

We tried very hard to provide as clear and thorough a description of our project facilities and operation. I'm hoping that when you get a chance to take a look at it, it's a helpful guide for you.

So with that said, on to the description of the project. These facilities are licensed under two separate FERC licenses. We have Ripogenus, which is licensed as Project 2572; and then we have Penobscot Mills, which is licensed as Project 2458. And although they're separate licenses, we will file separate license applications for them, they both have the same expiration date; they are right above each other on the West Branch. And so we elected to relicense them essentially as a single unit in order to pick up some efficiencies and reduce paperwork, and the amount of meetings. So that's why we had chosen to do this the way we have.

So what I will do now, I'm just going to walk

through a very high level overview of the projects. I'm going to start at the top of our system, I'm going to work down through the facilities. So we'll start with the Ripogenus Project, and we have one kind of interesting development, Umbazookssus, which is -- it's part of the project. It is a wetlands mitigation project that came out of the last license. But it's not a functioning, working reservoir. So we aren't manipulating flows up there to affect the project; the water is just flowing out of that, naturally run-of-river. Because like I said, it's a run-of-river mitigation project that we have established.

But water runs down from Umbazooksus into the Ripogenus impoundment, and the Ripogenus impoundment has several sub bases within it that are part of that larger impoundment. So you have Ripogenus Lake, you have Caribou Lake, Chesuncook Lake, you have Moose Pond, Brandy Pond and Black Pond -- all of these are part of that Ripogenus impoundment which is created by the Ripogenus Dam.

There's no generating facility at the dam itself. Water is diverted down to McKay station, which is the generator station associated with Ripogenus. So McKay is a 37.5 megawatt generating facility. Water goes into McKay, discharges back into the West Branch, and then, that is largely the end of the project features associated with the Ripogenus. What you saw was the footprint of it. You look

at the size of it, it's pretty enormous. We've got almost 30,000 acres of impoundment.

But it's primarily those two facilities; Ripogenus Dam and McKay station. There is a very long transmission line that is part of the project, but in terms of river -- really we don't go much below the station as part of rivertine.

So that's it for that project. And now I'll talk a little bit about the Penobscot Mills Project, which is much more complicated because it has many more moving parts, so to speak. I'll start at the top of the Penobscot Project with the North Twin impoundment, and again the North Twin impoundment, Ripogenus is composed of separate sub-base that are a part of that.

So North Twin, Elbow Lake, North Twin Lake, South Twin Lake, Pemadumcook Lake, and Ambajesus Lake. So water from McKay comes down the West Branch, reaches North Twin impoundment.

We also have, as part of this system, Millinocket which we can pump water from into North Twin when we need to augment flow. From North Twin, water then goes to North Twin generating station; that's a 6.9 megawatt facility. Water from North Twin casts down into Millinocket Lake; and then Millinocket, Quakish Lake and Ferguson Pond.

At Millinocket Lake we currently have two

components there. We have Stone Dam and when we have Millinocket station. So most of the water is diverted via Stone Dam to Millinocket station. That's a 37.4 megawatt station.

From Millinocket it discharges back downstream, enters Chaz Pond, which is actually outside the project boundary. Chaz Pond, the water travels to Dolby impoundment, and from Dolby the water runs through Dolby station; that's a 16.5 megawatt station. Passes from Dolby back into the West Branch, follows the river down to the East Millinocket impoundment. This is our smallest impoundment in the system.

And then from East Millinocket it goes to East Millinocket station, which is a 7 megawatt station; and then from there it goes back into the West Branch, and that's the bottom of our project.

There are some very helpful things, some maps, high level maps of these projects from that PAD, as well as this very handy diagram. I'm not going to kid you, I'm looking at the diagram as I'm going through the description of the facilities. It very clearly lays out where the water is going; it also has specific details on how much water and when some of these operating requirements we have are in place.

So again, my pitch for the Pre-Application

Document here, because I just really think it will be a useful reference document for you to look at.

And with that, Allan, I think that concludes my overview of the projects here.

MR. CREAMER: Okay, thank you, Randy.

I think, Julie, we are ready to begin our comments.

OPERATOR: Thank you. One moment.

VOICE: ..via FERC.gov or by mail. Written comments are given equal consideration...

OPERATOR: We'll go ahead and place you in your breakout room. Just to confirm, where should Speed go?

MR. CREAMER: Place them in Breakout Room 1.

OPERATOR: Room 1, okay. That's good.

All right. You're moving now.

MR. CREAMER: Thank you.

(Pause)

MR. CREAMER: Hello.

VOICE: Hey, Allan.

VOICE: Who do we have in this breakout room?

VOICE: This is Steven.

VOICE: So just us?

VOICE: Welcome, and thank you for participating. You are now in the room so that you make your comment to the court reporter. You will have five minutes to speak. I

will give you a warning when you have 30 seconds remaining. Please state, tell your name for the record and whether you're speaking on behalf of a group or an affiliation.

And you may begin your comment.

VOICE: Hey, Allan?

MR. CREAMER: Yes.

VOICE: I think I heard -- that may have been tape coming in. Did you hear that?

VOICE: Oh, this is Cate Russel at HDR. I've been --

MR. CREAMER: Oh, you are here. Okay. All right.

(Pause)

VOICE: Hello and thank you for participating. You are now in the room to provide your comment to the court reporter. You will have five minutes to speak. I will give you a warning when you have 30 seconds remaining. Please state and spell your name for the record and whether you're speaking on behalf of a group or an affiliation.

MR. OUELLETE: Yes, my name is Richard R R-i-c-h-a-r-d O-u-e-l-l-e-e-t-e. And I am the President of the [static] Association on South Twin Lake. We have roughly 200 members on the Lake, and we are very pleased with the operation that Brookfield has been providing over the years.

They have maintained a water level at recreational levels very well. We haven't had any issues where we've had major flow increases or decreases, especially this year with the drought conditions that we've had. I feel that they have done an excellent job of maintaining water flow for both the rafting people on the West Branch as well as the camp owners and homeowners on South Twin Lake.

The number of camps on the lake has grown over the years, and we have been there for roughly 24 years; and within the last 5 years a number of instances of camps being turned over and replaced by yearly residents.

So we feel that it's stewardship of the fields, that they have done an excellent job, and we would be happy to have their license renewed for the, whatever number of years; I'm not sure if it's ten years or twenty years or what have you.

That's my comment.

MR. CREAMER: Thank you for your comment.

VOICE: Thank you. We will include your comments in the public record for this project and they will be entered into consideration for the project.

You may now --.

One moment.

(Pause)

VOICE: Hello and thank you for participating.

You are now in the room to provide comment to the court reporter. You will have five minutes to speak. I will give you a warning when you have 30 seconds remaining. Please state your name and spell it for the record, and whether you're speaking on behalf of a group or affiliation.

MR. FORTI: Okay, good evening, everybody. My name is Peter Forti, F-o-r-t-i. I am a local landowner up on Tarifee Lake, Lake Caribou, and I was listening to this morning's presentation, and all I heard was the thought of, "Well, we don't know. You'll have to find out about this; we're missing documents" and then it shifted to water flows. Which doesn't really address any of these issues.

One thing I would like to address, and I'm going to make this short and sweet -- is the water levels north of your dam. You go up to Lake Caribou right now, it looks like a testing site for NASA for future Mars programs. It's a barren lake, there's nothing in there. And as a landowner for so many years, I've seen progressively the water levels continue to drop year after year after year. And as a taxpayer, I get my taxes raised every year, and my water levels get reduced.

So it's not fair to the recreational people that have places north of Rip Dam and use the upper lake for recreational purposes. So I just ask the Board to consider, when they're going through this to do something

about maintaining the water levels at least on Lake Caribou. All right? There's no reason why that lake has to be a barren pit.

That's all I have to say.

VOICE: Thank you for your comment. We will include your comments in the public record for this project and they will take -- in the review of the project.

You may now --

MR. FORTI: Thank you.

VOICE: Please stand by for the next speaker.

Hello, and thank you for participating. You are now in the room to provide your comments to the court reporter. You will have five minutes to speak. I will give you a warning when you have 30 seconds remaining. Please state, tell your name for the record and whether you're speaking on behalf of a group or an affiliation.

And you may begin your comment.

(Pause)

VOICE: Hello, and thank you for participating. You are now in the room to provide your comments to the court reporter. You will have five minutes to speak. I will give you a warning when you have 30 seconds remaining. Please state and spell your name for the record and whether you're speaking on behalf of a group or affiliation.

You may begin.

MS. SCHMIDT: Katheryn Schmidt. I am a resident of the Penobscot River watershed. I am here to speak on behalf of, we run Atlantic salmon and other fish. The Ripogenus and Penobscot Mills project should not be relicensed unless they provide upstream and downstream passage for fish that migrate between the West Branch Penobscot River and the ocean.

Historical records tell us that sea run salmon came all the way up the West Branch, past Chesuncook and Spednic Lake, into the North and South Branches of the Penobscot River. There was a time on the West Branch with excellent salmon habit.

According to fisheries biologist Charles Atkins, writing in 1874, quote: Of the tributaries in this part of the Penobscot, the Millinocket, Nanacasa, Oagna, Caribou and Cocomgama Stream are particularly well-suited to be the breeding grounds for salmon. End quote.

In 1866, Edward G. Masterman of Greenville told Charles Atkins that quote: In August and September of any year, he can catch young salmon from 6 to 12 inches long at Ripogenus Falls. And Joel Lane reported that one night in November 1838 he speared nine large salmon on Ripogenus Falls. Joe Francis, Maine Fish Commissioner Charles Atkins made of Penobscot -- saw them in Penobscot Brook, the headwaters of the West Branch.

The removal of West Branch from Atlatic Salmon habitat began during the 19th Century when loggers transformed the landscape in order to move trees to the downstream sawmill. By the middle of the 20th Century, pollution from paper mills on the West Branch prevented any salmon that survived from getting past the dam, whether built for log driving, holding loss for generations.

As they disappeared from the river, fish habitat and map salmon restoration. It is not clear why this, but the result has been that, for more than a century, the West Branch is sacrificed for electricity generation that is not as necessary nor as renewable as it was once believed to be. The costs are too great. Salmon are on the endangered species list and we, all of us -- not just the Penobscot Nation or NOAA, or U.S. Fish and Wildlife Service, are obligated to prevent their extinction.

Right now these dams are preventing recovery of Atlantic salmon, and it is time the West Bank be included in restoration efforts. Otherwise, we can continue to violate the return of the species.

I hope that effective fish passage be required as part of the studies in consideration for these relicensings. Thank you for the opportunity to comment.

VOICE: Thank you for your comment. We will include your comments in the public record for this project

and they will be considered in the review of the project.

You may now end the call.

MS. SCHMIDT: Thank you.

(Pause)

VOICE: Hello and thank you for participating. You are now in the room to provide your comments to the court reporter. You will have five minutes to speak. I will give you a warning when you have 30 seconds remaining. Please state and spell your name for the record and whether you are speaking on behalf of a group or affiliation.

And you may begin.

VOICE: Is there somebody there?

VOICE: Yes. I was just hoping to kind of listen if I called.

VOICE: If you don't have any comments to make, I don't think that that's what we were planning to do. I mean, people are moved into the room to provide comments, and that's it.

VOICE: Oh, okay. I didn't have any comments necessarily prepared.

VOICE: That's fine. If there are any comments that you would like to make, you can have time to do that, five minutes. Actually less than that now.

VOICE: Yeah, I don't have any. I'll send something in writing. Okay. Thank you.

(Pause)

VOICE: Hello and thank you for participating. You are now in the room to provide your comments to the court reporter. You will have five minutes to speak. I will give you a warning when you have 30 seconds remaining. Please state and spell your name for the record and whether you are speaking on behalf of a group or affiliation.

And you may begin.

MS. RUSSEL: This is Cate Russel. Allan, are you still on?

MR. CREAMER: Yes, I'm here.

MS. RUSSEL: Okay. I just wanted to make sure my line didn't go dead.

(Pause)

VOICE: How many people were here and what kind of participation?

MR. CREAMER: You know what? I'm not really sure if -- I was just thinking about that myself, whether I can ask Julie how many people we had total that were transferred over at the end. I mean, she was managing all of the name transfers, as I understand it.

What's that?

VOICE: We had a good turnout this time.

MR. CREAMER: Yes.

(Pause)

VOICE: ...sounds like they have three comments on the other line as well.

(Pause)

VOICE: This is the conferencing operator. I wanted to let you know that right now we don't have anyone queued up for comment at this time. So we stand by.

MR. CREAMER: Okay. Thank you.

(Pause)

VOICE: Hello and thank you for participating. You are now in the room to provide your comments to the court reporter. You will have five minutes to speak. I will give you a warning when you have 30 seconds remaining. Please state and spell your name for the record and whether you are speaking on behalf of a group or affiliation. Then begin your comment.

And the caller has disconnected.

(Pause)

[Staff chatter]

MR. CREAMER: Well, it's interesting, because our Verizon person was in a different place, with a voice over last time, when we thought we had somebody on.

I was thinking to myself, "Huh, can we combine rooms already?"

VOICE: That's -- yes, I was wondering.

MR. CREAMER: Because I was wondering if that's

possible.

OPERATOR: Excuse me, this is the operator, by the way. I just took over for a short time while A was on break.

MR. CREAMER: Okay.

OPERATOR: So sorry about that, guys.

(Long Pause)

VOICE: Hello and thank you for participating. You are now in the room to provide your comments to the court reporter. You will have five minutes to speak. I will give you a warning when you have 30 seconds remaining. Please state and spell your name for the record and whether you are speaking on behalf of a group or affiliation.

And you may begin.

MS. HOPPER: My name is Siona S-i-o-n-a Hopper, -p-e-r, and I am speaking on behalf of myself, though I do work for the Portland Public Schools. And in my role at the Portland Public Schools, I am the District Wabanake studies coordinator, and I have had the great fortune of working with many Penobscot people as well as meeting leaders from other Wabanake tribes. And I am not a natve person, but I have been increasing my own education and understanding of impacts of dams on rivers.

I live in the watershed of the Penobscot River which, like many rivers including the West Branch of the

Penobscot, has been really devastated by daming, and many other severe impacts to the ecosystem.

And so I am speakng in hopes that the West Branch of the Penobscot River will have dams removed and the stewardship of that river will be returned to the Penobscot Nation. I really hope that there have been many people speaking on behalf of the river tonight. It is critical for the Penobscot Nation and of course everybody who lives in the land. It is a huge watershed and a vibrant ecosysem, and all of us have a responsibility to ensure that that ecosystem can regenerated and passed on for generations.

As far as the economics of it go, I don't pretend to be an expert in that area, but we know that that whole entire region is a destination for wildlife and and wilderness lovers, and I would imagine that there's a huge opportunity with the restoration of the ecosystem of the West Branch, usher in positives, go tourism related to development hopefullly led by local communities and by the Penobscot Nation.

And I would also just say as an educator and a teacher that having ecosystems intact so that students can learn direct from the watersheds around them is critically important and also part of students learning to be responsible for the places in which they live.

So I would urge FERC to make sure that they're

taking all of the information that has been presented by those who came from the Penobscot Nation, take all of that into consideration, and think about the long term impacts of potential inaction and make the right decision to decommission and remove all of the dams in the West Branch. Thank you.

VOICE: Thank you for your comment. We will put your comments in the public records for this project, and they will be considered and be reviewed by the project team.

You may end the call.

MS. HOPPER: Thank you very much.

(Pause)

[Staff chatter]

[Whereupon, at approximately 8:30 p.m., the comment session concluded.]

CERTIFICATE OF OFFICIAL REPORTER

This is to certify that the attached proceeding before the FEDERAL ENERGY REGULATORY COMMISSION in the Matter of:

Name of Proceeding:

Ripogenus Hydroelectric Project and

Penobscot Mills Hydroelectric Project

Great Lakes Hydro America, LLC

Docket No.: Project Nos: 2572-133, 2458-247

Place: Virtual

Date: Thursday, September 9, 2021

were held as herein appears, and that this is the original transcript thereof for the file of the Federal Energy Regulatory Commission, and is a full correct transcription of the proceedings.

SCOPING SESSION - TELECONFERENCE

Thursday, September 9, 2021

The Virtual Scoping Meeting, pursuant to notice, convened at 9:00 a.m.

P R O C E E D I N G S

OPERATOR: Welcome, and thank you for standing by. All participants will be able to listen-only until the question and answer portion of today's conference. At that time you may press *1 on your phone to ask a question.

I would now like to turn your conference over to Mr. Allan Creamer. Sir, you may begin.

MR. CREAMER: Thank you. Welcome, everyone to the Federal Energy Regulatory Commission's Virtual Scoping Meeting for the relicensing of the Ripogenus Hydroelectric Project, No. 2572, and the Penobscot Mills Hydroelectric Project, No. 2458.

My name is Allan Creamer, and I work in the Office of Energy Projects, Division of Hydropower Licensing at FERC, and I am the project coordinator for these proceedings. Several other FERC staff are joining me today, along with representatives of Great Lakes Hydro America and Brookfield Renewable, will listen to you as you provide comments during the scoping process.

The purpose of scoping is to seek input on the specific concerns or environmental issues related to relicensing the projects and to identify alternatives that should be considered in our environmental document.

I will begin by going over important meeting notes, and will continue with a short introduction to the

licensing process and schedule. Great Lakes Hydro America will then provide a short presentation on the projects and their operation.

Following Great Lakes Hydro America's presentation, we will begin taking your comments. As we all know, these virtual meetings are not routine for the Commission; in fact, it's the first instance for hydro licensing. I thank everyone now for your patience while others are being heard.

For those wishing to speak, we have a court reporter to transcribe today's meeting. This transcript will serve as part of the Commission's record in these proceedings. When prompted, we ask that you please state and spell your name clearly, and provide information on any affiliation or group to which you are speaking before beginning your comments.

After Commission Staff introduction to the licensing process and Great Lakes Hydro America's introduction to the project, you will be invited to speak in the order we received your call. With the setup for this meeting, we will all listen together as comments are presented by each of you. Please follow directions from our Verizon operator during this time to provide comments.

Nearing the end of your allotted time, the operator will prompt you to finish, and will then move to

the next in line. After providing the comments, you can remain on the line, and we will finish the meeting with a Q&A session.

If you prefer not to speak today, or wish to file comments for any other reason, you can file written comments with the Commission by October 9th, 2021. Instructions for filing written comments are on page 2, paragraph O of our August 10, 2021 notice. We encourage you to eFile your written comments.

For those of you who wish to be on the FERC mailing list, official mailing list, please see the instructions on page 34 of our Scoping Document 1, also issued on August 10th, 2021.

Finally, we recommend that you go to FERC's website, at www.ferc.gov and eSubscribe to the project using Project Nos. P-2572 and/or P-2458, which are the project numbers to the Ripogenus Project, 2572, and the Penobscot Mills Project, 2458. Doing this will ensure that you are notified of any filings with the Commission or any issuances by the Commission related to these projects.

I'll now switch gears and introduce the licensing process and our schedule, and we'll then turn it over to Great Lakes Hydro for its introduction to the projects.

Great Lakes Hydro America has chosen to relicense the Ripogenus and Penobscot Mills Projects using the

Integrated Licensing Process, or ILP. The ILP is the Commission's default licensing process. The process is driven by a process plan with defined timelines and deadlines for all participants, including Commission Staff. The first step in the process is development of a Pre-Application Document which is prepared by the applicant after gathering information from resource agencies and other sources.

The process is marked by early scoping as well as study plan development and resolution of any study disagreements. Specific criteria are used to develop focus and appropriate studies, and a Commission-approved study plan is developed in consultation with the stakeholders. The study criteria are presented in Appendix A of Scoping Document 1.

There are two years for studies, so there is an opportunity to reduce study results and make adjustments to the study plan based on specific criteria. Towards the end of the prefiling process, the applicant is required to develop a preliminary licensing proposal, or draft license application that includes a proposal for relicensing the project.

Process is also designed to integrate stakeholder process with respect to the Commission's licensing process, the Maine Department of Environmental Protection's water

quality certification process, consultation under the Endangered Species Act, and the Federal agencies fishways process. Thereby improving the overall efficiency of the licensing process.

So where are we in the relicensing process for Ripogenus and Penobscot Mills? The relicensing process begins with an applicant filing a Notice of Intent and a Preliminary Application Document. Great Lakes Hydro America filed these documents on June 11, 2021. Commission Staff issued its Scoping Document 1 for the projects, and the Commission issued a public notice of the proceeding on August 10th, 2021.

Commission Staff is holding virtual public scoping meetings including Great Lakes Hydro America's virtual environmental site review of the project today, September 9th, 2021.

Stakeholders then have an opportunity to file comments on Scoping Document 1 and the Pre-Application Document as well as file study requests by October 9th, 2021. Once the comment period ends, Great Lakes Hydro America will prepare a proposed study plan which is due by November 23rd, 2021. There will be a meeting to discuss the study plan on or around November 23rd, 2021. This represents an informal opportunity to resolve disagreements with the studies.

Comments on the proposed study plan are due by February 21st, 2022. After which Great Lakes Hydro America will file a revised study plan, and the Commission will issue a study plan determination by April 22nd, 2022.

If necessary, there is a formal dispute resolution process that follows issuance of the study plan determination. The ILP process provides for two years of studies, which for these projects occurs in 2022 and 2023. Great Lakes Hydro America will file an initial study report by April 21st, 2023 and a final study report by April 21st, 2024. Meetings will be held for each report. Great Lakes Hydro America will then file a Preliminary Licensing Proposal, or PLP, by May 3rd, 2024. Stakeholder comments on the PLP are due by August 1st, 2024.

The prefiling part of the process, the Great Lakes Hydro America filing license applications for the two projects by September 30th, 2024.

I know I've gone through a lot of information. what I presented was intended to be an overview of the process. Details can be found in Appendix D of Scoping Document 1.

Also, as you can see, this is a fast track process; actually in the first eight to ten months, and it is a process to provide for stakeholder involvement throughout.

At this point I'm going to turn the meeting over to Randy Dorman of Great Lakes Hydro America, talking about this project and their operations.

MR. DORMAN: Thank you, Allan. Good morning, everyone. I'm Randall Dorman, I'm Licensing Manager for Great Lakes Hydro, and I'll be managing the relicensing of the West Branch relicensing. This is going to include Penobscot Mills and Ripogenus.

As Allan said, I'm going to be giving a very brief overview of these projects; but really these are very large and very complex facilities; there are multiple types. And so I'd really urge anyone who hasn't already to take a look at our Pre-Application document. You can find that on the FERC website.

We tried very hard to prepare a fair and thorough discussion of our project facilities and operations. In addition to that we are also going to be holding a virtual site review this afternoon at 1:30. And we are going to have some video and PowerPoint, I think, to better illustrate these projects. So if you wish to sign up and you haven't done so already, you can send an e-mail to Cate Russel at HDR, Inc.com. And that's Cate with a C. Cate.Russell@HDRInc.com. That's to sign up for the virtual site review at 1:30 this afternoon.

So on to the project. These facilities are

licensed under two separate FERC licenses. We have Ripogenus, Project 2572, and then Penobscot Mills, which is Project 2458. Although they're separate, they have the same expiration dates and we elected to relicense them essentially as a single unit just in order to gain some efficiencies, cut down on paperwork, and the number of meetings. So that's why we're proceeding this way.

So let me do just a very quick walk-through over these projects. I'll start at the top of the system with Ripogenus. And we have Umbazookssus, which is a reservoir that flows into the Ripogenus impoundment, and the Ripogenus impoundment actually consists of several smaller bodies of water; so that's Ripogenus Lake, Caribou Lake, Chesuncook, Moose Pond, Brandy Pond, Black Pond -- those are all within Ripogenus, and there's no generating facility at the dam itself. Water is passed from the dam down to the McKay (ph) station; the generating of Ripogenus -- that's a 37.5 megawatt station.

McKay discharges into the left branch, and that, all of the Ripogenus facilities talking about, these are all associated with the Penobscot Mills, which actually has quite a few more components to it.

So we'll start the overview of Penobscot Mills with the north impoundment, which like Ripogenus consists of several smaller bodies of water; so we've got Elbow Lake,

North Twin Lake, South Twin Lake, Pemadumcook Lake, Ambajesus Lake.

Water comes into North Twin from the West Bank below a station, or Millinot, which is also part of Penobscot Prospect. So from North Twin the water at North Twin Station, that's a 5.9 megawatt station; and then discharges from there down to Millinocket impoundment. That includes two water bodies, Quakish Lake and Ferguson Pond. That in turn flows to Millinocket Lake, that's a 37.4 megawatt station.

That again, below that is Shad Pond, which is not actually in the project boundary, but continues down from Shad Pond to the Dolby Impoundment and Dolby Station. Dolby Station is 15.5 megawatts. That in turn goes back into West Branch to the East Millinocket station with 7 megawatts, and then that goes back into West Branch, and that is the lowermost facility that we'll be talking about today.

Allan, I think that's it for my overview of the project.

MR. CREAMER: Okay, thank you, Randy.

At this point I would ask if there were any specific questions with regard to what we've covered on the licensing process schedule and the facilities.

So Julie, if you want to go to the lines for that.

OPERATOR: Thank you. If you would like to ask a question or make a comment, please press star-one. You will be prompted to record your first and your last name with affiliation. To withdraw your question, press star-two.

And once again, to ask a question, make a comment, it is star-one. One moment, please.

We do have a question or comment. One moment.

Our first question or comment comes from Casey Clark, with NBMR.

Your line is open.

MR. CLARK: Thank you. My question was just about the scope of the project. You said it was complex; I was wondering if either FERC or Great Lakes Hydro intends to have it for a longer process, licensing. That's the end of my question.

MR. CREAMER: Thank you. This is Allan Creamer with FERC. The process is designed, they have to file their application by November 30, 2024. They've got a defined timeline to get to that point, and they're up to that point.

After that, we will process the application according to the timelines that we will post when the applications are filed, and typically we do try to issue new licenses within two years before the expiration. Doesn't always happen that way, but that's what our goal is.

So I think along the way, the path of trying to

complete these in the time frame that the ILC provides for. At this point we're not expecting to do anything beyond that time frame.

OPERATOR: Once again, to ask or make a comment, it is star-one. Our next question/comment comes from Jeff Murphy with National Marine Fisheries Service.

MR. MURPHY: Hi. Can you all hear me?

MR. CREAMER: Yes.

MR. MURPHY: Oh, great. Thank you.

First, I would echo concerns that given the complexity of the projects, it's going to be extremely difficult, perhaps even impossible to navigate all these issues in two years. So I would urge the Commission to consider those concerns.

But my question is, when these projects were first constructed, power was exclusively for the people, you know, of the Millinocket market regions. And the power, even by state law, had to be used exclusively for paper production.

So I suspect that when the Great North Paper Company owned and operated these projects, they were operated very differently than they are today. So I think it would be helpful for everyone on the call if Great Lakes Hydro could explain to folks how these projects were first used and operated, to today when they are used for ISO New

England; and how those operations they have changed over the past, those many years. Thank you.

MR. DORMAN: Is Mike Osborne -- he is our water management operations person. And if he's on, Jeff, I think he'd be in the best position maybe to talk at very high level in the time we have about this.

If not, I think we would probably want to hope, that's something we could potentially talk about during the site review this afternoon.

OPERATOR: Mr. Osborne, if you are on, please press star-zero. Once again, Mr. Osborne, if you are on, please press star-zero.

One moment. He has signaled.

MR. OSBORNE: Hello. Can everybody hear me?

MR. DORMAN: Yes.

MR. CREAMER: Yes, we can hear.

MR. OSBORNE: So essentially the paper mill, after hard times, economic downturn, multiple ownership changes and what not, the East Millinocket mill went down in 2013, the Millinocket mill went down in 2008. However, there are ongoing economic development efforts with the towns of Millinocket, East Millinocket, other nonprofit entities and how other stakeholders to try and bring businesses back to those mill sites and utilize some of this hydropower to support that.

MR. MURPHY: Thank you.

OPERATOR: Once again, to ask a question or make a comment, it is star-one. One moment, please.

(Pause)

OPERATOR: We do have another question or comment. One moment. A. Murphy with National Marine Fisheries Service.

MR. MURPHY: Hi. Can you hear me again?

MR. CREAMER: Yes.

MR. MURPHY: I promise not to take over these calls.

For the record, National Marine Fisheries Service will be submitting formal comments on the application documents, and will file a study request.

But could you start with the PAD itself, and some of the assumptions in the PAD? I note that there are few if any proposed studies in the document, the ecological additions that are in the project areas. And from my perspective, primarily fisheries, that Great Lakes Hydro is proposing to update with the fisheries resources areas. The fisheries resources, the project areas.

Forty years ago, I know the extent and the effort that we engaged in in documenting the fisheries resources in areas, and I think that what the licensee is assuming is that in particular fisheries resources are the same as they

are today, and that's true.

You may recall in the previous license, fishways weren't installed because certain species, in particular small mouth bass, but we know today that small mouth bass are the dominant fishery than the fish that has invaded, probably non-native, maybe even in the Upper Wash area.

I believe that the project is operated differently than it was in the Eighties when all the power was consumed by paper production; and there was more or less a constant demand for power. And what we're seeing today is peak, peak in operation of these stations, twins.

I think if we continue down this path that the fisheries resources today are the same as they were in the Eighties, it will be fundamentally flawed because fisheries resources are significantly different. And not only fisheries, but most environmental resources are different today than they were in the Eighties.

So I would suggest, given that the only have, perhaps even just two years to gather this information, that the licensee should immediately start re-documenting the environmental baseline position for all environmental resources, in particularly fisheries resources in the project area.

I know that the Great Northern Company did a number of mark and recapture, age and grow populations,

spawning survey. All those studies have to be repeated because the conditions today are not the same conditions that they were in the Eighties. The condition under NEPA analysis, assuming conditions today are the same as they were in the Eighties, that they will be fundamentally different from the onset.

So again, my recommendation is that the licensee, even this fall, start to re-document things like fisheries resources in the project area. Thank you.

MR. CREAMER: Thank you, Jeff.

OPERATOR: Our next question-comment comes from Robert Nesbur. Your line is open. With American Whitewater.

MR. NESBUR: Thank you. I have a couple of questions or comments on this section.

First, the PAD always deals with the battery storage component here. Are we going to be addressing that issue today as well? And I'd like some clarification on how the battery storage is used. Is that just for environmental mitigation? Or to take advantage of spot markets or other peaking opportunities? That's my first question.

JIM: Randy, this is Jim. I'd be happy to take that question if it's helpful.

MR. DORMAN: Go for it, Jim.

JIM: So Bob, the battery -- and this is addressed in the PAD and we'll talk about this tomorrow at

1:30. But the two battery disburse facilities that have been established, they are not a mitigation measure, and they change no aspect of project operation.

What they do, as compared to peaking, what they do is they provide grid stability for ISO New England. So as ISO New England needs grid stability in this part of the state, the battery systems that we're dispensing help support that effort.

MR. NESBUR: That's helpful, thank you.

The second question is, the PAD describes different developments that are either peaking or run-of-river. And I guess I'm a little confused by that.

Would it be accurate to say that being both projects are, both Ripogenus and Penobscot Mills, are both influenced, the flows are influenced by the peaking operation at Ripogenus, so that all of the Penobscot Mills project, generate based on the peaking inflows from Ripogenus?

JIM: Randy, I can touch upon that as well, if it's helpful. And once again, we kind of outline this in the PAD.

So I give our predecessors a lot of credit and foresight in terms of -- that this system, the Ripogenus impoundment, the North Twin impoundment, Millinocket Lake, working in conjunction with the upstream storage project,

and what those ponds collectively do is they provide that constant base flow down through the remainder of the West Branch; and then when the West Branch converges with the East Branch, and then further downstream.

So those base spawning flows, those base fishery flows, everything that we see downstream starting downstream of North Twin, that is coming from the fluctuation, the allowances that are allowed at Ripogenus, North Twin, and Millinocket Lake.

So Bob, to your question, those ponds are being used to manage really the larger watershed, and then you -- to your point, you do get into a series of run-of-river facilities at the Millinocket development, the Dolby development, the East Millinocket development -- which are the ones that Randy referred to earlier --and then we go further downstream to Medway, Madacina, West Enfield, and further downstream. Yes, those are all run-of-river facilities based on the ace flow being provided by the upstream facilities.

BOB: But I take it it wouldn't be accurate to describe it as a natural hit by the upstream fluctuation, correct?

JIM: That's exactly correct. Especially if you look like a year at, like today, this year. If that fluctuation flexibility did not exist, as we look further

down on the West Branch and then obviously on the main stem, you wouldn't have those flows that are established throughout the system.

So once again, those North Twin impoundment, Millinocket Lake and Ripogenus impoundment, they act as the, kind of the base water that feeds the rest of the system.

BOB: Thank you.

OPERATOR: Once again, if you would like to ask a question or make a comment, please press star-one.

One moment, please.

Our next question or comment comes from Chaz Murphy with National Marine Fisheries Service. Your line is open.

MR. MURPHY: Hi. Thanks again. I apologize for all my questions, but.

Just in response to Jim's statement, as I mentioned earlier, I believe the projects were significantly operated differently than they were in the Eighties, and particularly the operations at McKay station and North Twin that flow throughout the summer and into the fall, very high water, a magnitude of probably from, flows from 18 to 2800 at McKay station during the day. And you'll see similar operations at North Twin as peaking.

As I mentioned, actually very curiously the license to contrast operations, done only outflows at the

project; track daily outflows, days in the 1980s but also impoundment level. But in any event, given that we know the case is operated in run-of-river mode, and is North Twin, and the projects operate in tandem with North Twin. That while they are licensed as run-of-river facilities, their inflow equals outflow, they are in fact, in a sense, peaking themselves, as inflow on a daily basis causing a change from North Twin and McKay station.

So just want to make sure that's a correct, clear that while those lower projects may be licensed as run-of-river facilities, they are not, there's no -- it's not a steady state of outflows from those projects, so we need to be very clear about that; that that's how they are operated.

Thank you.

OPERATOR: Our next question or comment comes from Casey Clark with MPMR. Your line is open.

MR. CLARK: Yes, thank you. Also following up on that question about operations at the projects, and I noted that in the PAD in Section 5.3 you provide summaries, tables, river flows, as the project starts the year, and I was going to ask if you're intending to provide more detailed information, and that would be something along the lines of turbine operation or something else we can actually see river flow as a -- no, there's no USGS gauging or any other way for us to have an external way to review how

these projects are operated except for that one summary table, more data would be important.

JIM: I guess, this is Jim again -- I think that would be a logical conversation to have in the context of the study to be performed, provide such information. So yeah, I think if that comes in as a study request, it would be logical information at that time.

OPERATOR: Once again, to ask your question or make a comment, please press star-one.

One moment, please.

We do have another question or comment. One moment.

Our next question or comment comes from Julie Ann Rosset with U.S. Fish and Wildlife Service. Your line is open.

MS. ROSSET: Good morning, this is Julie Ann.

I just had a question to follow up on Casey's, I just want to make sure that I'm understanding. So there is no data related to the flows exiting these facilities that are available to the agencies? It's only Brookfield that is able to view that information?

Can you confirm that that's correct?

JIM: Randy, this is Jim. I think we have to talk with Mike or someone in terms of what data is readily available to others. Obviously, it kind of gets back to

Jeff's earlier comment.

There are the prescribed whitewater flows coming out of McKay station. There's obviously the 2000 cfs requirement. There's a number of flow requirements throughout the system. I think to Casey and Julie Ann's question, actual flows, we're going to have to check with just what's available and in what format it exists.

[MR. DORMAN:] I think that's correct, Jim. I think the executive summary probably is, in the absence of USGS gauges, the data is not readily available to agencies or the public, for that matter.

MS. RUSSET: Okay, thank you for clarifying.

OPERATOR: Our next question or comment comes from Casey Clark with MDMR. Your line is open.

MR. CLARK: Yes, sorry I need to comment on this, and then to clarify your response there, Jim.

I would see this as a data request, not as an actual study. I would ask you to estimate flows or really cleaning up the data and providing it so we have access to it; and I would expect that we really need that soon so that we can base our study requests upon it. Thank you.

OPERATOR: Once again, to ask a question or make a comment, please press star-one [*1].

If you have a question or comment. From Steven Hines of Trout, Unlimited. Your line is open.

MR. HINES: Yes. This kind of builds on the DMR and the National Marine and Fisheries Service comments. There is a lot of reference to prior studies that are, have aged out, and I guess, you know, when I think we're faced with is a process problem, because if we rely on, if we're going to rely on these studies, we need to know what's in them and most of these are so old, I don't have copies of them, and I don't know how to obtain copies of some of it.

So I guess what I would ask and propose is that there be a mechanism set up where if Brookfield is going to be using these studies, you know, as part of their license application, that we're given access to them and then at least 60 days to review them. You know, what we're going to be up against is -- you know, it's kind of like, kind of a "trust us, these studies are good" we may not be able to get access to them, and then when the deadline comes for submission of the study plans next month, you know where are we then?

I mean, I guess this is really a process question. I hope Mr. Creamer would address this.

MR. CREAMER: Okay, so at this point in time we're - we do need to look at what data is available and what the quality of that data is. And I guess that's -- I mean, that's where we are, and moving forward then we decide what data gaps need to be filled, and that becomes what the

study plan is.

So to the extent that there's, you know, the previous studies are out there, you know -- I know they're summarized in the PAD, but it probably would be helpful if those studies were available somewhere, whether they're in the record at the Commission on eLibrary, which is preferable. But I know we've talked about this before, the possibility of a relicensing website where things can be deposited and available for people to look at.

But it does make sense; I mean if you're looking at what studies need to be done, you need to know what's there now. And if the stakeholders don't have that opportunity to know what current studies say, that does become a bit of a problem.

MR. HINES: Well, thanks for acknowledging that, Allan. So what I'm asking is, can we set up a mechanism -- you know, Brookfield perhaps put this in some cite out on the cloud and then can we have -- I mean, if they're not going to use any of these studies, it doesn't matter; we don't care. If we're starting from zero, then it just doesn't matter.

But if we are going to be using studies going forward, we need to know what's in them so that we can have those study requests to fill in the gaps by next month. And as has already been noted, this is a huge administrative

undertaking. I mean, when you look at all of the dams and the waters that are affected by these two relicensings, it's much bigger than anything that happens in the State of Maine and in the FERC relicensing world.

So if we just kind of pretend that this is OPS-normal, I really don't think we're going to get an outcome that's going to be a good one. So is that something that you can take for action, sir?

MR. CREAMER: Well, it's something that we can certainly look at and try to figure out where, you know, the best place, this information is taking place. You know, we have had, like I said, a conversation with Brookfield, so -- with possibility of setting up a relicensing website.

I don't know where they area on that; but certainly if -- you know, the information that's in the PAD is based on those prior studies. So somewhere along the way, the PAD's in the record, the supporting documentation for the PAD must be there as well.

Whether or not it's in -- on a relicensing website that Brookfield sets up, it's still information that should be available on eLibrary in this office for these projects.

MR. HINES: I agree --

MR. CREAMER: Those old study reports and things of that nature should be available in the public domain.

MR. HINES: I agree, and I would just ask that until they are, it's going to take us at least 60 days -- you know, just based on what's in the PAD, it looks like Brookfield intends to use substantial amounts of information that was collected quite a while ago.

I think some of the most recent data is about 15 year old, and some more than 30. And once again, given the size of the project, it's really problematic. So I would hope that we would have 60 days from when this stuff is made available to us to be able to submit study requests. Because until we know what is going to be used, this is going to put us behind the power curve and really behind the eight ball, as far as my experience goes with the FERC process.

So I really hope that something can be done to address this. Thank you, sir.

MR. CREAMER: Okay.

JIM: Steve, this is Jim --.

MR. CREAMER: From the standpoint of the process plan itself, the only way that we can change the process plan is we get requests to change the process plan. And then we all would have to agree that those changes are necessary.

So I mean it's not something that we're going to do necessarily right off the bat. We would have to look at

whatever, you know, on a case-by-case basis, and whether or not change, and that those deadlines are appropriate.

But in the meantime we can certainly have conversations with Brookfield, Great Lakes Hydro folks about those studies, and what's available and trying to find a place where it is publicly available.

[STEVE:] Right. We're facing deadlines to have study plans presented by-- you know, in early next month. So time is of the essence.

MR. CREAMER: Yes, Steve. I understand. So are we. We're stakeholders in this just like you. So we're in the same position.

VOICE: I guess Steve and Allan just put their case -- I think what we're hearing is, there are some reasons these studies are in the PAD. Folks are looking for the original reports.

VOICE: Correct.

MR. CREAMER: Yes, that's what I hear. That seems to be what I'm hearing.

VOICE: Okay.

VOICE: I mean, we did go through and we analyzed them, and thought we were synthesizing it, and bringing information together which we thought was helpful, but -- we hear the request for the actual reports.

MR. CREAMER: I would say we can certainly

discuss this. You know, as soon as the reports are available --. We can talk about that process and how best to make it happen, but I do think it would be the sooner the better that they are available.

OPERATOR: We do have another question or comment from Jeff Murphy with National Marine Fisheries Service.

Your line is open.

MR. MURPHY: Hi. Great conversation. And I would just suggest for the record that commentary on the PAD be extended until after all these studies, given the reliance on past studies be extended to review all those studies, if in fact the intention is to base the entire relicensing on those studies done 40 years ago. So I would certainly hope that FERC would immediately grant an extension to allow us to fully absorb all that information. Thank you.

MR. CREAMER: Jeff, as I said before, you're going to have to request, or parties are going to request, stakeholders are going to have to request an extension.

If it's your desire to have had an extension to a specific deadline, then the best thing I could advise is file that request for an extension.

MR. MURPHY: Thank you, Allan.

OPERATOR: Once again, to ask a question or make a comment, please press star-one. One moment.

(Pause)

OPERATOR: I'm showing no questions at the moment.

(Pause)

MR. CREAMER: This is Allan Creamer with FERC.

The one thing I would be interested in, let's throw this out there, is the scoping document. I would like to hear some opinions, comments with regard to the scope of issues that we identified, and I would also ask if anybody has any comment that they would want to make at this time, feel free to do so. Or we can discontinue the question and answer session.

OPERATOR: We do have a question or comment from Robert Nestur with American Whitewater.

MR. NESTUR: Thank you. With regard to the scoping document, my question is whether project decommissioning is being looked at as an alternative at any of the projects; and I'm specifically interested in knowing whether that's being looked at at the two lower projects, East Millinocket and Dolby as it relates to fish passage.

MR. CREAMER: Thank you, Robert.

As of now, the way we address dam decommissioning, if you were to read the scoping document. Up until that time, we had no information to suggest that it was an alternative that people wanted to look at.

And so the scoping document right now identifies dam decommissioning as an alternative considered but eliminated from detailed review.

MR. NESTUR: So if the organizations or agencies wanted that to be considered as an alternative, they would include that in their comments by the upcoming deadline for submitting study requests?

MR. CREAMER: You can comment on the scoping document, and the alternatives, and the issues; that would be the place to do it.

MR. NESTUR: Thank you.

OPERATOR: Our next question/comment comes from Casey Clark with MDMR. Your line is open.

MR. CLARK: Yes, thank you.

Specific, the sections on data in the PAD, I will note that there are a couple of pieces that are missing from that; both species of River Herring would be Blueback Herring and Alewives, Sea Lamprey, and we do believe that lamprey are likely present within this project area currently. And then the section on American eel implies that eels are able to enter these projects without any impact. That is absolutely false, and we will be pursuing a request for actual eel counts as part of our formal comments.

OPERATOR: Our next question or comment comes

from Jeff Murphy of the National Marine and Fisheries Service.

MR. MURPHY: Thank you. I do have a comment on Section 4.1.2 in Scoping Document 1, on water and aquatic resources.

FERC proposes to assess the effects of continuing projects, given seasonal release operation of the Ripogenus and Penobscot Mills projects, on fisheries resources -- I think that is updated -- to assess the effects of daily peaking on fisheries resources.

I don't think seasonal storm release adequately portrays that actual operation of the project. Thank you.

MR. CREAMER: Okay, thank you.

OPERATOR: Once again, to make a question or comment, please press star-one [*1].

We have a question or comment.

Our next question comes from Daniel McCaw, Penobscot Indian Nation.

MR. McCAW: Thank you. Good morning.

My name is Daniel McCaw, and I have the pleasure to work for the Indian Nation as a fisheries resource manager, fisheries program manager. And I just want to say my thanks to the Federal Energy Regulatory Commission on the line today, and my thanks to both the Great Lakes Hydro and Brookfield for their time in looking at the issues with

regards to the license.

As you may know, or may not, Penobscot has inhabited the Penobscot watershed since time immemorial. I would personally like to thank the Penobscot elders, both past, present and future, for my ability to be here on this landscape that is their ancestral home. It's traditional in Indian country to say things like that, and I'm glad that I can bring them to these proceedings today.

I just have a few comments that I'd like to make rather quickly with regard to goals and issues that the Penobscot nation has identified with these relicensings. As my colleagues, both federal and state have expressed very eloquently, and Mr. Hines. This is a very complex project, and it will take a lot of hard work by a lot of parties in order to execute this relicensing process.

The Penobscot Nation will be involved in every step of the way. The Penobscot Nation was involved in these relicensings in the 1990s. I think it is accurate and important to remember that hydro relicensings are not strictly issues, they're not strictly habitat issues or wildlife or flow issues. Hydro licensings are social issues.

We, the peoples of the State of Maine and our friends and visitors, we live here. This is our home. It used to be the home of the Atlantic salmon. It is our

home, too, and so the social concerns given, need to be certainly looked at and explored and understood by all parties. Mr. Murphy was correct in saying that the last relicensing was vastly different than today's. Great Northern Paper was the largest employer in Penobscot County; it was the second largest employer in the State of Maine at the time of the last relicensing.

Dozens and dozens of state legislators wrote FERC comment letters during the relicensing process, pleading with the FERC to consider the economic effect on the entire region, as thousands of people, thousands of small businesses were linked into and dependent for their living on the mills that operated in Millinocket, East Millinocket -- not just the people who worked at the mills, but the entire community that supported those mills, and provided for those people.

The social landscape has changed, dramatically. Now we have an energy investment company; I don't know if that affects current owners, but we have an energy development company who is Ace in a foreign country, and the energy today is generated -- it's not to support an entire region, what was known today, still known today at least to Colonial folks, is the Katadonry (ph), the entire region. But it's not sustained today, and I'm hopeful that the PAD, although it does have some excellent information in it, the

PAD seems to be a document that looks at the entire picture by looking at a one-by-one inch frame in the corner, and the rest of it is not seen or mentioned.

And I am hopeful that through the comments on the PAD and through the FERC's diligence and fiduciary responsibility as a stakeholder, that we can shine a light on this relicensing that we will also experience only once in our career. Mr. Creamer, you may have participated last time, and my boss, John Banks, did it last time. But there's very few who will participate in the next one on this call today.

I'm hopeful that we can consider this not as a fish issue, not as an eel issue or a salmon issue, although they are all intertwined; this is a watershed issue, a people issue and a social issue and an energy issue. And in the face of climate change, which is the greatest threat to human health - greater than the pandemic -- we must make the right decisions today not only for our tribal brothers and sisters but for all people in the State of Maine and all people in the United States.

And I thank you for the opportunity to speak today, and I look forward to participating in future calls on this most important subject. Thank you.

MR. CREAMER: Thank you very much for your comments.

Yes, I was around and did see the original, or the licensing back in the 1990s. As a matter of fact, I did work with the applications. That's as far as I went with it, but as I was around to see it.

OPERATOR: Once again, if you have a question or to make a comment, please press star-one.

We do have another question or comment, one moment.

Our next question comes from Dean Vopane with Ambajejus Lake Y Owners Association. Your line is open.

MR. VOPANE: Good morning. Thank you for the opportunity to speak. Not only am I on this call, but I participated in the original relicensing in the 1990s, and I've probably forgotten more about this project than I learned this time around.

I am President of the Ambajesus Lake Lot Owners Association. We have over 200 members. We are part of the hundreds of recreational and terminate year-round residences on these impoundments. And one big change from the last time to this time is that at the first relicensing, these recreational and full time year round residences were on leased land. Since that time, the vast majority have purchased their property and have a tremendous investment. And any changes in operation, especially to lake levels, has to take into account the impact on the hundreds of Maine

citizens.

Even though the entities have been devastated by the loss of the paper industry, Brookfield remains the largest taxpayer, town of Millinocket and in the town of East Millinocket. And any talk of decommissioning has to consider the impact on the entity, or any act of that nature.

Thank you. That's all I have to say this morning.

MR. CREAMER: Thank you for your comment.

OPERATOR: Once again, ask a question or make a comment, please press star-one.

One moment.

(Pause)

We do have a question coming from Steven Hintz with Trout, Unlimited. Your line is open.

MR. HINTZ: Yes. There have been a number of flow occursion, excursion events over the last ten years; instances where minimum flows have not been -- generally they've been through the weather events. Can you tell me just how often these have been happening and when the last flow excursion occurred?

JIM: Randy, this is Jim. I think that's information we could probably -- but Steve, I don't think we have that information at our fingertips at this time.

MR. HINTZ: From looking back, it looks to me like there's about, at least ten instances of this. This has happened with some frequency over the years. Can you say at least that much?

JIM: Just for clarification, you're talking about ten times over the last ten years?

MR. HINTZ: Yes.

JIM: We can confirm that.

MR. HINTZ: Okay. Thank you, sir.

OPERATOR: Our next comment comes from Robert Ander
with American Whitewater. Your line is open.

MR. ANDER: Is this a meeting where we can comment on our general concerns or interest in particular resources? Or is that at a later time in today's agenda?

MR. CREAMER: No, you can comment on that now if you'd like.

MR. ANDER: Just very briefly, I just want to flag a few issues for you. We are, many of you may know, a national Whitewater River Conservation and Recreation organization. We have a great interest in the Penobscot River. It's a very important whitewater recreation resource, and we certainly have been appreciative of the whitewater releases from the -- station. It's important throughout the whole Northeast Region and the recreation

economy; certainly in the Millinocket areas, folks travel up to that area for really some unique whitewater boating there.

But the relicensing raises a couple of issues that I want to flag. Obviously it's an opportunity, a once-in-a-generation opportunity to look at the use of the resource for recreation currently; what opportunities may exist in the future that we should be exploring.

There are three that I'd like to identify, and of course we will follow them up with written comments and study requests. At the Ripogenus project, we have a great interest in the bypass reach below the dam; I believe it's a three quarter mile reach there, with fishing gradients that provide whitewater recreation opportunity. We'll be looking at -- have put together a boating study, look at appropriate flows below the dam, directly below the dam, between there and McKay station.

We believe that pictures of flow, access to the Penobscot River below the dam as well as flow information are the issues that we expect to explore. We'll also be looking at issues of flow access information at the powerhouse currently, and ways in which that can be improved if necessary.

At the Penobscot Mills project, there are several issues that we are looking at. The Millinocket Lake

storage, there are upflows, Millinocket stream, my understanding is that there is a minimum flow there, but we believe that that's essential for whitewater recreation or other types of recreation for the Millinocket Stream that are being influenced by project operations and the use of those waters for the hydropower operations that might alternatively be used to provide whitewater recreation. Issues of flow access and information are all ones that we would expect to address in our comments and study requests.

Lastly, the issue that I want to highlight; I believe it's the Millinocket project, the natural river channel or bypass reach there, does potentially provide an additional opportunity for whitewater recreation if sufficient flow access and information is provided there.

So it's really these three bypass reaches that are drawing our attention, and we expect to file some study requests to better understand the project operation; studies to identify minimum acceptable and optimal flows in each of those bypass reaches, and how that opportunity might be improved through relicense. Thank you.

MR. CREAMER: Thank you, Robert.

OPERATOR: Our next question or comment comes from Daniel McCaw with the Penobscot Indian Nation. Your line is open.

MR. McCAW: Thank you. Hi, this is Daniel McCaw

again with the Penobscot Nation.

Mr. Creamer, I have two questions that I'm hoping you can help me with. The first question is: In light of climate change and the dramatic changes that have been documented in our global environment, a lot of federal agencies have received guidance in many forms with regard to how they should update, change or manipulate their operations and decision-making processes to incorporate those decisions under the lens of climate change.

And I'm curious, has the FERC, the regulatory commission, received any guidance in any form with regard to climate change and how to adapt their processes under that lens?

MR. CREAMER: We generally, we look at things on a case-by-case basis. Climate change is not specifically looked at; however, if there are objects, we might look at it to some extent. But we don't -- it's not a normal practice.

MR. McCAW. I see, thank you. And to your knowledge, Mr. Creamer, has there been any guidance from any federal agency or within the FERC itself to incorporate a new standard and/or new processes with regard to climate change?

MR. CREAMER: The only thing that we are operating under right now are the new NEPA regulations.

Those are the only ones that I'm aware of that we are doing. There are also some new regulations concerning water quality certification and how that works into our process.

Those are the only two that I'm aware of where we have recently updated our practice in terms of how we look at things.

MR. McCAW: Excellent. Thank you, sir. I appreciate your answers and your knowledge on the subject.

The other question I have for you, Mr. Creamer, and again I appreciate your time today. Back in July of 2018 in the U.S. Court of Appeals in the District of Columbia Circuit Course, there was a case settled between American Rivers and the Alabama Rivers Alliance against the FERC and the Alabama Power Company. My understanding is that the decision made on that day in 2018 reprimanded the FERC for not considering the baseline position during their environmental analysis as the original, un-damed position.

And I'm curious, if that decision in 2018 has had any affect on FERC operations or if there's been any guidance passed down through the FERC to folks like yourself who handle these projects to take into consideration the decision that was made that day in 2018?

MR. CREAMER: You know, the only thing that I will say in regards to that, and then I believe we have, our staff attorney is on the call, too, and I might ask them to

jump in. But I am fully aware of that court case and that decision; that was a case that I was involved in, and we do -- our baseline is the current conditions. And it's my understanding of that court case where it's talking about the baseline, we were asked to look at the baseline as it pertained to I think threatened and endangered species. And how we went through our Endangered Species Act consultation.

I think there was also some discussion relative to that set. So obviously it's been three years since then, and the way we do things now has been adjusted. You know when a court case comes out, adjustments are made in how we handle projects. So to say that we didn't make some adjustments, I would probably not be telling you the truth. There have been adjustments made but not just solely for that reason.

Is Abigail out there on the line? And can she be moved over?

OPERATOR: Yes. Abigail, if you could please press star-zero.

One moment, she has signalled.

MR. CREAMER: Okay, thank you.

OPERATOR: Abigail has joined.

MR. CREAMER: Hey, Abigail. I was kind of hoping you could touch a little bit about on the people aspect of the 2018 case involving Alabama Power and the FERC, and how

that has affected what we do.

ABIGAIL: I think you've covered it well, actually, Allan. Anything further, and it would be best if it was a written discussion.

MR. CREAMER: Okay, that's fine. You know, I tried to keep it general.

ABIGAIL: Yes. No, I appreciate that. Thank you.

MR. CREAMER: I just wanted to give you a chance to weigh in or comment on that aspect.

ABIGAIL: That's what I'm comfortable saying. Thank you.

MR. CREAMER: Okay. I guess that constitutes our answer to that question.

ABIGAIL: Yes.

MR. McCAW: Well, thank you, Mr. Creamer. I appreciate that, and Attorney Abigail, I'm sorry, I missed your last name, but thank you for your time today. It's certainly something that I know the stakeholders here in Maine are concerned about.

Would it be appropriate with comments to the PAD or with the Notice of Intent, Scoping Document 1, those kinds of things -- would that be an appropriate venue to ask for additional information to understand the guidance that the FERC is currently under? And if so, the challenge that

I would find if that is the case, is that in preparing study requests I think it would behoove us to know what the current guidance is for the FERC with regard to that court case.

So would it be possible for me to submit a written request today and try to get some information for myself, the Penobscot Nation, and my stakeholders?

MR. CREAMER: My response to that would be certainly you should submit a request for clarification with those things, and then anything that we would provide would also be in the public record.

MR. McCAW: Excellent. Thank you, sir, for your time.

OPERATOR: Once again, to ask a question or make a comment, please press star-one.

If you have a question or a comment. Steven Hintz, your line is open.

MR. HINTZ: Yes, a question. In different places in the PAD, it talked to access in terms of both project and non-project use recreation sites. I know, and this is something I do myself, I do get access to the West Branch there below the powerplant on down to the Falls, and so do other people, there are pull-off sites where people park.

This, you know, as far as I can remember going back at least 25 years, there's always been access allowed.

But just looking back through the PAD, I'm not seeing anything where this is formalized in any way; it appears that it's only discretionary, and I don't see it as a prior license condition.

It would seem like at this point there would almost be an easement established by the user; but I'm unsure. Would someone from Brookfield just describe if the allowed access fishing point is discretionary, or is it a license condition, or what is it?

[Brookfield] I don't believe it's a license condition.

MR. DORMAN: Yes. And I think, Steve, you've brought up a great point, and that is throughout this system you have a mix of different entities and recreation sites. So obviously there's the one. We highlight -- those that are (inaudible) -- but then between the Penobscot River, between woods, there's another tab; let's say managerial rights on these lands.

So we try to in the Pre-Application Document to explain that as well as possible. If there are questions, I think those would be the type of questions to include in a letter and we would address those over the course of the proceeding.

MR. HINTZ: I mean, we can certainly put that in a request for information as part of our PAD comments, but

as I just wondered if there was -- you know, it seems like there'd be an easy answer. You know, if it's discretionary it's discretionary. Is it?

I mean, the reason why I'm asking is there have been areas near a project, a number of Maine projects that Brookfield is the licensee where the access has been fenced off for different reasons so -- that are Brookfield's reasons. Like for instance below the powerhouse, that could be used.

In years past could be, climb down on the rocks below where the water comes out and fish from there and get some fish. And that's all fenced off now, has been for years.

It's things like that are what is prompting my question.

VOICE: Randy, we may need to pull someone else in. I mean, I think you bring up a great point in certain areas. From a public safety perspective and a security perspective, there are some areas that have been fenced off.

My only hesitation is there are those defined areas where formal recreation sites have been established. I think there's going to be areas around each of the facilities that have public access. It's just that there's some areas where, in the private land and managed by others. It's just hard to say without looking at a map and talking about specific areas.

MR. BURNS: Kevin Burns here, from Brookfield.

To definitively say that -- I'm pretty confident that's not a project --.

VOICE: So essentially, so what you're saying is it is -- it's discretionary, correct?

MR. BURNS: This is Kevin Burns. The Great Lakes Hydro America is not only the area that Steve was talking about, downstream of a station; those areas are part of the areas that were granted to the State of Maine in I believe it was 1981. So it's been quite a while. Those areas are kind of -- and (inaudible) those areas. I believe they're -- by, depends, forest management. And it definitely is not Great Lakes Hydro America and it's out of the project boundary.

So we really don't have any say over what goes on downstream near that station.

VOICE: So I'll have to review the documents; and I thought they were part of the project boundary. I'll have to review that. Thanks for the response.

MR. BURNS: Thank you.

OPERATOR: Once again, to ask a question or make a comment, please press star-one.

If you have another question or comment. Steven Hintz, Trout.

MR. HINTZ: Yes. A couple times this morning

we've talked about the dewatered reaches of the main stem of the Penobscot River which exist in the Upper Gorge and below Stone Dam. These are impaired waters, and as I understand environmental law, there should have been an attainability analysis, a use attainability analysis performed on those.

The PAD does represent one for the waters upstream, you know, in the impoundment above Rip Dam, but it doesn't include the content of that. If these documents exist, we've already talked about reliance on old studies and prior things that happened 30 years ago. Can we get those, if they exist? And could we have that provided along with the other documents that are referenced when that gets resolved?

MR. CREAMER: Randy, I leave that question to you.

MR. DORMAN: There is no UAA for either of those locations.

MR. HINTZ: Okay, and can you guys provide the ones for Chesuncook and the impoundment upstream of Rip?

MR. DORMAN: We can look. I don't know that I have seen that document. I've seen --

MR. HINTZ: You referenced it in the PAD; that's why I'm asking, yes.

VOICE: Yes.

MR. CREAMER: If you talk about it --.

VOICE: All right, go ahead.

MR. CREAMER: This is Allan Creamer. If you're talking about a use attainability analysis, isn't that something that could be gotten from Maine EDP?

VOICE: Is this a question for Brookfield?

MR. CREAMER: I'm just throwing that out there. You know, we're talking about a user attainability analysis and where the information is, and trying to get the information. I would think that it's information that would be on Maine's EDP website or -- and/or the EPA's website.

Am I mistaken on that?

VOICE: No, Allan, I think you're correct. and to that point, we referenced it in the PAD; it exists; I've seen some summary documents on it. I don't know if we've seen the actual product that came out of the process.

But let us take a look, and obviously that's -- a general theme of the conversation this morning is that some of the studies that we summarized and other aspects, folks are looking for the original documents.

VOICE: If we don't have it, EPA or EDP would have it,

MR. HINTZ: Well, I guess my point is is that if we're going to reference these documents in the PAD, you know, we would certainly like access to them. Once again, we're looking at a very long temporal face here, and if

Brookfield is saying these documents exist, great. You know, let's see them. That's what we're asking, and I would certainly hope that they could provide this for us if they are going to reference it.

OPERATOR: Once again, to ask a question or make a comment, please press star-one.

(Pause)

We have a question or a comment coming from Steven Hintz with Trout, Unlimited.

MR. HINTZ: Yes, just one final question. The Upper Gorge which is called the bypass reach, I guess looking back, it looked like this was designed to improve the water quality downstream -- in the gorge and downstream. Is that warm water or cold water that's coming into the bypass channel? Is there data on, temperature data on how the bypass channel gets watered? It happens every year between July 1st and September 30th. Is there data on that? And what the effect of it is on the Maine flow downstream?

MR. DORMAN: I believe -- this is Randy -- I believe there is data.

Kevin, are you still on?

VOICE: Can you hear me?

MR. DORMAN: Yes.

KEVIN: The 100 cfs is discharged through log sluice, a former log sluice so it comes out the surface.

Although actually right now we're discharging it through a GP, of the lower water level.

So it's whatever the -- you know those sources is at the time. I'm not aware of any water quality or water temperature monitoring that's been done on that water.

VOICE: Thank you, sir.

I guess as a follow up, though, would the information exist into how that -- I know you do have a -- it is part of the licensing conditions that you do have to release that 100 cfs, to water the Upper Gorge for three months out of the year.

Is there data available that says, that shows what the source of that water is?

VOICE: I'm not sure if we have data on the actual source of the water. I mean, 99.9 percent of the time it would be from the surface. You now, we're in a drought right now and that's the only reason that we're releasing water here at the gate.

So I'm sure we have information on when the gate was open and when it was closed, which would be July 1st to October 1st every year. But I'm not sure -- I don't know if we have information on how it was -- almost all the time it's from that log sluice.

MR. HINTZ: But that's not exclusive. As I recall I guess when you had the head of one of these flow

excursions and then had to -- you know, do some corrective action to get things working the way they were supposed to to prevent that, that this isn't the first time that you've used the gate to provide that additional 100 cfs, correct?

VOICE: Again, I'm not sure if it's been done before. If it has, it's been quite a while. I mean, we didn't have a drought like this since 2001-2002. When we have a flow occlusion or a facia tripped or something like that, then yes, we need to open the gate to resume river flow, to do that. That's separate from cfs that's required to be released prior to September, every summer.

MR. HINTZ: Thank you.

OPERATOR: Again, to ask a question or make a comment, please press star-one.

At this time, I'm showing no comments.

Once again, if you would like to ask a question or make a comment, press star-one.

(Pause)

I'm showing no questions or comments. If you would like to ask a question or make a comment, press star-one.

(Pause)

I do have a question or comment coming from Robert Nuster with American Whitewater. Your line is open.

MR. NUSTER: Can you clarify the structure of

bypass reaches -- the Rip dam, on and in the third bypass reach of the Millinocket Project? I'm specifically interested in the capacity of those structures to release variable flows into those bypass reaches.

MR. DORMAN: Randy. I can speak in general in these types of gates here. Bob, I think in terms of getting let's say gate to pass the information over your way, we can do that; I just don't think we have that at our fingertips at this time.

Probably the most downstream, referring to Stone Dam. So there's a series of flash boards there, inflatable bag, and that's the primary release into that system is from overtopping of that spillway.

Like Kevin said, we've got some sluices up at the Upper Gorge, that jump in from the top there, into that bypass reach. And at Middle Dam there is a gate release there. But unless somebody else knows off the top of their head, we're going to have to follow up with that information.

MR. NUSTER: I think you understand the question. It's beyond what minimum flows might be required at those various locations. I'd like to understand whether the project has the ability to provide naturally-occurring flows into those sections of the river.

VOICE: Yup. You're just looking to get a better

understanding how water flows through those structures and what piping and equipment currently exists. Is that a fair statement?

MR. NUSTER: Yes.

VOICE: Certainly if you want to follow up with the individual, that's fine.

VOICE: We can provide that information.

OPERATOR: Once again, to ask a question or make a comment, please press star-one. One moment.

We do have a question or a comment coming from Steven Hintz with Trout Unlimited. Your line is open.

MR. HINTZ: Yes. There are pumping operations between Millinocket Lake and Ambajejus Lakes, and how much do the water levels vary at either of those lakes due to the pumping operation?

VOICE: Kevin, do you have that off the top of your head?

VOICE: (inaudible) the pumping of water levels, that I don't have off the top of my head. I do know Millinocket Lake is lower than the north plant pilot. Of course it depends on, you know the difference depends on the water level on each one of them. It's a matter of several feet. That's really all I can say generally.

VOICE: Okay, we'd have to ask specifically, I guess, for more information. And that would include the

North Twin Lake as well, correct?

VOICE: North Twin Lake is part of the North impoundment. So (inaudible) station, the Ambajejus Lake portion of the North impoundment and then it would run into Twin Lake.

VOICE: Okay, thank you.

OPERATOR: Once again, to make a question -- if you have a question, make a comment, please press star-one.

Our next question or comment comes from Daniel McCaw, the Penobscot Indian Nation.

Your line is open. Mr. McCaw?

MR. McCAW: Oh, I'm sorry. I was on mute. My apologies. I was trying to be polite, but evidently too polite. Thank you for the ability to ask another question.

My question is this, and is directed to Mr. Creamer from FERC. Mr. Creamer, a few moments, a FERC attorney named Abigail was on the line. I was wondering if you could give me Abigail's full name and how I would reference her.

MR. CREAMER: Her name is Abigail Kristof, and she is our staff attorney assigned to the project.

MR. McCAW: And Mr. Creamer, could you be so kind as to spell Attorney Kristof's last name for me, please.

MR. CREAMER: Good question. I believe it's -- and she can correct me -- C a r i s c o p h.

MR. McCAW: Excellent. Thank you so much for your time, Mr. Creamer. I appreciate it.

MR. CREAMER: No problem.

OPERATOR: Once again, to ask a question or make a comment, it is star-one.

(Pause)

I'm showing no questions or comments at this time. But once again, if you would like to ask a question or make a comment, it is star-one.

(Pause)

I'm still showing no questions or comments.

MR. CREAMER: If we don't get anything further in the next minute or two, we have reached 11 o'clock, which was the two hours for the meeting.

OPERATOR: Okay.

(Pause)

OPERATOR: I do have two minutes after the hour, and I'm still showing no questions.

MR. CREAMER: Okay, I think we're going to go ahead and wrap up. So this is Allan Creamer with FERC. We have reached 11 o'clock or two minutes past 11. The meeting was scheduled from 9 to 11, and if there are no further comments or questions, then we can wrap this portion of the meeting up. And I would thank everyone who participated, a lot of good information, a lot of good questions, a lot of

good comments. Certainly look forward to reading the comments that come in and look forward to the virtual site tour coming up this afternoon.

OPERATOR: Thank you for your participation.

[Whereupon, at 11:05 a.m., the meeting concluded.]

CERTIFICATE OF OFFICIAL REPORTER

This is to certify that the attached proceeding before the FEDERAL ENERGY REGULATORY COMMISSION in the Matter of:

Name of Proceeding:

Ripogenus Hydroelectric Project and

Penobscot Mills Hydroelectric Project

Great Lakes Hydro America, LLC

Docket No.: Project 2572 & 2458

Place: Virtual Meeting

Date: Thursday, September 9, 2021

were held as herein appears, and that this is the original transcript thereof for the file of the Federal Energy Regulatory Commission, and is a full correct transcription of the proceedings.

DAN HAWKINS

Official Reporter

September 13, 2021

Kimberly D. Bose, Secretary
Federal Energy Regulatory Commission

Washington, DC 20426

**RE: Extension of Time Request for the Ripogenus (FERC No. 2572-133) and Penobscot Mills (2458-247) Hydroelectric Projects**

Dear Secretary Bose:

We are requesting an extension of time to file comments on the Pre-Application Document (PAD) for the Ripogenus and Penobscot Mills projects. Additionally, as detailed below, we are requesting additional information that is missing from the PAD.

On September 10, 2021, the National Marine Fisheries Service (NMFS) attended the Ripogenus (FERC No. 2572) and Penobscot Mills (FERC No. 2458) virtual scoping meeting hosted by the Federal Energy Regulatory Commission (Commission). At the meeting, stakeholders noted that, to date, Great Lakes Hydro America, LLC (GLHA; Applicant) had not provided the studies referenced in the Pre-Application Document (PAD). However, in the PAD the Applicant states "…GLHA maintains that a full suite of new studies is not needed, that the vast body of information on which today's certifications and licenses are soundly based and should be relied upon for these relicensings. In addition, consistent with the Commission's criteria for study requests, the scope and extent of any new study be focused on addressing specific data gaps necessary to inform the development of license requirements." While broad summaries of the studies performed during the last relicensing were provided in the PAD, a refined synthesis of the data was not provided, nor did GLHA identify any data gaps. Consequently, without the original studies, stakeholders cannot identify existing data gaps to inform their respective study requests. Therefore, we request that you require the Applicant to provide stakeholders with each study referenced in the PAD and asks that the Commission grant a 90-day extension of time, from when the studies and associated additional information (see below) are received, to submit PAD comments and study requests for the Ripogenus and Penobscot Mills licensing proceeding. We also request that you require the Applicant provide us with 10 years of operations data for each project including: 1) daily impoundment elevations; 2) daily outflows for each project (minimum, maximum, and average daily discharge). These data are critical for us to develop comments on the PAD and identify data gaps and any new studies.

We would also like to express our disappointment with the general public meeting held by FERC for these projects during the evening of September 9, 2021. We understand the challenges associated with holding public meetings under the constraints necessitated by the current Covid-19 pandemic. However, the meeting participants, including agency staff and the public, were not

afforded an opportunity to hear questions and responses during the teleconference meeting. Instead, when a meeting participant posed a question to FERC or GLHA, they were placed on a private line so that the rest of the meeting participants could not hear the conversation. Depriving the resource agencies, stakeholders, and the public the opportunity to hear questions and responses during the public meeting was exactly contrary to the purposes of the public meeting. We request that FERC schedule another public meeting with open lines of communication where all participants are able to hear all questions and answers. Releasing a transcript of the public meetings is not enough as that still deprives the opportunity for someone to ask questions that would have been prompted by responses from FERC or the Applicant.

Please direct any questions regarding this request to Dan Kircheis at Dan.Kircheis@noaa.gov

Sincerely,

Julia E. Crocker

**RE: Extension of Time Request, Data Request, Legal information request and repeat of the Public Scoping meeting request for the Ripogenus (FERC No. 2572-133) and Penobscot Mills (2458-247) Hydroelectric Projects**

Dear Secretary Bose,

On September 10, 2021 the Penobscot Indian Nation (PIN) attended both of the Ripogenus (FERC No. 2572) and Penobscot Mills (FERC No. 2458) virtual scoping meetings hosted by the Federal Energy Regulatory Commission (the FERC). This included the morning session with Resource agencies and the Public meeting, held in the evening.

A relicensing of this size and scope will not happen again in Maine or the Northeast region of the United States for 40 years. The decisions made during this relicensing process will affect the entire West Branch of the Penobscot River, a drainage over 2,000 square miles and present and ancestral home of the PIN. The West Branch contained vast quantities of high gradient, cold water, and climate resilient habitat before it was dammed and industrialized to support the Great Northern Paper mills in Millinocket nearly 100 years ago. These antique structures, long past the life span of concrete, continue to negatively alter the social, economic and environmental systems of an entire region, for the economic benefit of a foreign energy company. It is imperative that decisions, comments and questions be built from a working knowledge of all the studies from the last relicensing, a assessment of the ecological potential of a dam-free West Branch, and present/past operating conditions at each facility.

The PIN believes that the best fish passage and the best chance for restoration of the West Branch Penobscot River ecosystems is dam removal for all the projects in this relicensing.

**Request for past studies and extension of time:**

Many stakeholders noted during the agency meeting that, to date, the licensee had not provided the studies referenced in the Pre-Application Document (PAD). As a representative for the licensee in the process, HDR employee Jim Gibson went so far as to say the licensee did not have many of the documents, and was relying on summary tables of unknown date, unknown origin and unknown author. Yet, the licensee states in the PAD:,

> "…GLHA maintains that a full suite of new studies is not needed, that the vast body of information on which today's certifications and licenses are soundly based and should be relied upon for these relicensings. In addition, consistent with the Commission's criteria for

study requests, the scope and extent of any new study be focused on addressing specific data gaps necessary to inform the development of license requirements."

The PIN finds this situation challenging in its efforts to assess the PAD and to submit comments and study requests. The licensee admittedly made statements in the PAD based on incomplete data and summary tables. The PIN empathizes with the FERC and all other stakeholders who find themselves in the same position. That is, a position of trying to respond and comment on a document based on incomplete data, and not knowing where fact may be found within the array of assumption and invention.

Stakeholders cannot identify existing data gaps to inform their respective study requests without the original studies referenced in the PAD.

The PIN requests that the licensee provide stakeholders with each study referenced in the PAD, the additional information requests outlined below, and asks that the Commission grant a ninety-day extension of time from when the studies/information are received to submit PAD comments and study requests for the Ripogenus and Penobscot Mills licensing proceedings.

**Additional data request:**

The resource agencies have also identified other data gaps that must be filled for the proper review and understanding of the issues of these relicensing's.

The PIN requests that the licensee provide 10 years of head-pond elevation and 10 years of daily flow conditions for each project involved in the relicensing (min, mean, and max flow) . This data is needed to understand flow conditions and operations on the West Branch of the Penobscot River, as there are no flow gauges on the system or other data available. This data would be critical to understanding the environmental impacts of the projects and to inform study requests. This information would have been appropriate to be included in the PAD.

**Legal information request:**

The PIN asked Mr. Creamer of the FERC during the Scoping meeting to explain the directives, orders, or other guidance documents that FERC relicensing staff were responding or operating under after the United States Court of Appeals for the District of Columbia circuit, No. 16-1195, American Rivers and Alabama Alliance v. FERC, and the US Dept. of Interior. The case was argued January 12, 2018 and decided July 6, 2018. (2018 decision) Mr. Creamer of the FERC was personally involved in the case as a FERC employee, and explained in general terms that the FERC normally will assess the project environmental baseline as the current conditions. He also seemed to indicate that endangered species issues and cumulative effects were some of the factors in determining if baseline conditions were indeed the ancestral condition or the present modified conditions. FERC attorney Abigail Christoph joined the call to clarify. She stated that the question would need to be asked in writing and that the FERC would respond in writing.

The PIN requests that the FERC provide the PIN and other stakeholders with any and all information with regards to the FERC response to the 2018 decision, and asks what guidance FERC staff has received with regards to the 2018 decision. For example, has the FERC changed its own statutes, procedures, laws or directives? Have there been changes in FERC process in other recent relicensing's in regards to the 2018 decision? Any information or documents the FERC could provide would be greatly beneficial for properly reviewing the PAD, drafting study requests and all other stopes in this massive relicensing.

**FERC Scoping meeting for the public, September 10th, 2021:**

The PIN would like to express its concern over the handling and execution of the Scooping meeting by the FERC. The FERC held a public scoping meeting by telephone, in response to guidance over the global Covid-19 pandemic. PIN staff attended the meeting and realized that a major deviation from the normal scoping process was happening. Scoping meetings for the public always allow for participants to hear the comments given by other stakeholders. This process allows the public to understand the issues, and to hear the diversity of interests from their neighbors and fellow citizen tax-payers. Only the first speaker of the night would not have the benefit of hearing what others may think of the issues at stake. In the Scoping meeting held on September 10th, 2021, no one got to hear the comments of the other interested parties. Citizens were

placed into a private, digital location from their phone line and had an opportunity to give a five minute comment. No person got to hear a single comment or question by any other interested parties.

The PIN believes this to be a major deviation from the public scoping process, and one that may have discouraged public participation through the process. The public scoping process touches a minimum of citizens and sometimes touches no one at all. Only those citizens who read the FERC website, read the Federal register, or read their local newspaper's legal announcement sections would have any idea a relicensing was occurring. Here in 2021, there has been an exponential increase in the number of information portals available to public and private institutions and people. The FERC has not adapted to the times in its public scoping techniques, and has done a further disservice to the tax-payers of Maine by not allowing them to hear the comments of their neighbors and other interested other parties, as is traditional in the Scoping process.

The PIN requests that the Public Scoping meeting for these relicensings be repeated at the earliest convenience. The Public Scoping meeting should provide the opportunity for stakeholder to listen to the other interested parties and to give their own comments in turn.

The PIN looks forward to hearing from the FERC in a timely manner. The PIN continues to review the PA and draft study requests. However the PIN is currently experiencing great challenges in this effort due to the missing studies, flow and head-pond elevation data and without any information of the response of the FERC to the 2018 decision. The PIN appreciates the opportunity to provide these comments and requests.

Please reach out if you have any questions.

Sincerely,

Dan McCaw

**RE: Extension of Time Request for the Ripogenus (FERC No. 2572-133) and Penobscot Mills (2458-247) Hydroelectric Projects**

Dear Secretary Bose,

On September 10, 2021 the United States Fish and Wildlife Service (Service) attended the Ripogenus (FERC No. 2572) and Penobscot Mills (FERC No. 2458) virtual scoping meeting hosted by the Federal Energy Regulatory Commission (Commission). At the meeting, stakeholders noted that, to date, Great Lakes Hydro America, LLC (GLHA; Applicant) had not provided (1) studies referenced in the Pre-Application Document (PAD); or (2) operations data for any of the projects. In the PAD the Applicant states "…GLHA maintains that a full suite of new studies is not needed, that the vast body of information on which today's certifications and licenses are soundly based and should be relied upon for these relicensings. In addition, consistent with the Commission's criteria for study requests, the scope and extent of any new study be focused on addressing specific data gaps necessary to inform the development of license requirements." While broad summaries of the studies performed during the last relicensing were provided in the PAD, a refined synthesis of the data was not, nor were any data gaps identified by the Applicant. Without the original studies, and without operations data for each dam, stakeholders cannot identify existing data gaps to inform their respective study requests or their PAD comments. Therefore, the Service respectfully requests that the Commission require the Applicant to provide stakeholders with ten years of operations data for each project including, but not limited to, daily impoundment elevation and daily outflows for each project (minimum, maximum, and average daily discharge). The Service also asks that the Commission require the Applicant to provide stakeholders with each study referenced in the PAD and that the Commission grant a 90-day extension of time, from when studies and operations data is received, to submit PAD comments and study requests for the Ripogenus and Penobscot Mills licensing proceeding.

Thank you for this opportunity to comment. Please direct any questions to Julianne Rosset at *julianne_rosset@fws.gov*.

Sincerely,

**RE: Extension of Time Request for the Ripogenus (FERC No. 2572-133) and Penobscot Mills (2458-247) Hydroelectric Projects**

Dear Secretary Bose:

The Maine Department of Marine Resources (MDMR) is requesting an extension of time to file comments on the Pre-Application Document (PAD) for the Ripogenus and Penobscot Mills projects. In addition, as detailed below, we are requesting additional information that is missing from the PAD.

On September 10, 2021, MDMR attended the Ripogenus (FERC No. 2572) and Penobscot Mills (FERC No. 2458) virtual scoping meeting that was hosted by the Federal Energy Regulatory Commission (Commission). Stakeholders noted during the meeting that Great Lakes Hydro America, LLC (GLHA; Applicant) had not provided the studies referenced in the Pre-Application Document (PAD). While the PAD included summaries of the studies performed during the last relicensing, a synthesis of the data was not provided, nor did GLHA identify any data gaps. Without the original studies, stakeholders cannot identify existing data gaps to inform their respective study requests. Therefore, we request that the Commission require the Applicant to provide stakeholders with each study referenced in the PAD and asks that the Commission grant a 90-day extension of time, from when the studies and associated additional information (see below) are received, to submit PAD comments and study requests for the Ripogenus and Penobscot Mills licensing proceeding. We also request that you require the Applicant provide us with 10 years of operations data for each project including: 1) daily impoundment elevations; 2) daily outflows for each project (minimum, maximum, and average daily discharge). These data are critical for us to develop comments on the PAD and identify data gaps and any new studies.

OFFICES AT 32 BLOSSOM LANE, MARQUARDT BUILDING, AUGUSTA, MAINE
http://www.Maine.gov/dmr
PHONE: (207) 624-6550
FAX: (207) 624-6024

We would also like to express our disappointment with the general public meeting held by FERC for these projects during the evening of September 9, 2021. When a meeting participant posed a question to FERC or GLHA, they were placed on a private line so that the rest of the meeting participants could not hear the conversation. We request that FERC schedule another public meeting with open lines of communication where all participants are able to hear all questions and answers.

If you have any questions or need additional information, please contact Casey Clark at casey.clark@maine.gov or (207) 624-6594.

Sincerely,

Patrick C. Keliher, Commissioner

TROUT UNLIMITED
MAINE COUNCIL

**Via online submission to: http://www/ferc.gov (cross-filed)**

Subject: **Preliminary Comments of Maine Council of Trout Unlimited on the Notices of Intent and Pre-application Documents for the Ripogenus Project (P-2572) and the Penobscot Mills Project (P-2458)**

Dear Secretary Bose:

On behalf of its six chapters and over 2,000 members, Maine Council of Trout Unlimited (TU) submits these comments on the Notices of Intent (NOI) and Pre-application Documents (PAD) for the Ripogenus Project (P-2572) and the Penobscot Mills Project (P-2458) filed for Great Lakes Hydro America, LLC by Brookfield Renewable ("Brookfield") dated June 11, 2021.

Taken together, these relicensings reflect over 108,000 kw of generation capacity making this the largest relicensing effort in the state of Maine in terms of electricity production. The waters and surrounding habitat affected by these relicensings are of equal stature. The land-locked salmon fishery below Ripogenus Dam is sustained by naturally spawned fish and nationally known for its quality. With Maine's highest mountain nearby, Ripogenus Gorge below the dam is Maine's most spectacular gorge. The waters of the Penobscot Mills Project are also important in their own right and should play a part in the restoration of sustenance fisheries to the Penobscot Indian Nation (PIN) that have been so long promised but not delivered.

Brookfield's submission places great stock in studies conducted many years ago during the last relicensing.[1] Many of the outcomes for the last relicensings of these projects occurred when the electricity produced went directly to the mills in Millinocket. Any increase in the generation costs would have a potential effect on the economic viability of the mills, and decisions were made on the basis of the jobs and politics involved, not the intent of Maine environmental law. Despite this, the mills are now closed and the electricity sold to the grid, so those factors should not be brought to bear in this round of relicensings. If we are to accept past data and past studies, stakeholders should know exactly what we are accepting and not have to rely on summaries provided by the applicant. Only then will resource protection agencies and stakeholders be able to generate appropriate FERC study requests. It must also be noted that many of the referenced studies are older than the 10 years specified for studies by the courts in American Rivers III.[2]

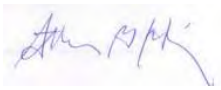
**Accordingly, TU strongly supports the request by the National Marine Fisheries Service: "*90-day extension of time, from when the studies and associated additional information (see below) are***

[1] Brookfield Notices of Intent and Pre-application Documents for the Ripogenus Project (P-2572) and the Penobscot Mills Project (P-2458) dated June 11, 2021, page 1-11. "*GLHA maintains that a full suite of new studies is not needed, that the vast body of information on which today's certifications and licenses are soundly based and should be relied upon for these relicensings. In addition, consistent with the Commission's criteria for study requests, the scope and extent of any new study be focused on addressing specific data gaps necessary to inform the development of license requirements.*"

[2] American Rivers and Alabama Rivers Alliance v. FERC and United States Secretary of the Interior, No. 16-1195 (D.C. Cir. 2018) ("American Rivers III").

***received, to submit PAD comments and study requests for the Ripogenus and Penobscot Mills licensing proceeding."***[3]

After preliminary review, TU specifically requests that the following, listed and followed by where they were first referenced in the PAD, be provided to all stakeholders or placed in on a Internet site where they can be readily accessed:



1. (MDIFW 2012) - page 5-92
2. (FERC 1996) - page 5-92
3. (GNNC 1991b) - page 5-93
4. (FishBase 2021c) - page 5-94
5. (GLHA 2011) - page 5-95
6. (MDMR 2021) - page 2021
7. (USFWS 2015a) - page 5-97
8. (Midwest Biodiversity Institute &Center for Applied Bioassessment and Criteria [MBI] 2005) - page 5-113
9. During the previous relicensing of the Project, the Licensee completed an instream flow study in the Upper Gorge to assess the relationship between river flow and aquatic habitat - page 5-117
10. MDIFW unpublished sampling data from 2017 and 2018 - page 5-122 (footnote)
11. Yoder et al. 2008 (Source cited for Lower Millinocket Stream and West Branch (Millinocket Tailrace to Dolby Pond fish assemblage) - page 5-125
12. Instream Flow Incremental Methodology (IFIM) study conducted by the Licensee in 1987 and 1988 in consultation with MDIFW and USFWS - page 5-127
13. An additional IFIM study was conducted on the "deadwater" sections of Millinocket Stream to compliment the initial IFIM study - page 5-127
14. IFIM Study (two sites) -page 5-131
15. (Nedeau et al. 2000) - page 5-133
16. (Swartz and Nedeau 2007) - page 5-133
17. (Swartz 2007) - page 5-143
18. (Dewan & Assoc., 1990b) - page 5-247

Additionally, any IFIM studies or any other documents that have bearing on the dewatering of the main stem of the West Branch of the Penobscot below Stone Dam that the Applicant refers to as a bypass.

Provision of these studies will allow stakeholders including the resource protection agencies to determine which studies are still viable and those that are not - and base their study requests on that determination.

Maine TU Council appreciates the opportunity to provide these preliminary comments on these important projects and hopes that the Commission will act to allow the resource protection agencies to identify potential harms to the resource and thus enable the Commission to balance project harms and benefits.

Respectfully,

Stephen G. Heinz
Maine TU Council FERC Coordinator

[3] National Marine Fisheries Service letter RE: Extension of Time Request for the Ripogenus (FERC No. 2572-133) and Penobscot Mills (2458-247) Hydroelectric Projects dated September 13, 2021.

**Subject:** **Ripogenus Hydroelectric Project (FERC No. 2572-133)**
**Penobscot Mills Hydroelectric Project (FERC No. 2458-247)**
**Response to Stakeholder Requests for Additional Information and an Extension of Time to File Study Requests and Comments on the Pre-Application Document**

Dear Secretary Bose:

Great Lakes Hydro America, LLC (GLHA), a subsidiary of Brookfield Renewable and Licensee of the Ripogenus Hydroelectric Project and Penobscot Mills Hydroelectric Project (collectively referred to as the "Projects"), herein files a response to recent filings by several entities requesting additional information and an extension of time to file study requests and comments on the Pre-Application Document (PAD).

On June 11, 2021, GLHA filed the Notices of Intent and PAD, which initiated the formal relicensing proceeding to obtain two separate new licenses for the continued operation of the Projects through the Federal Energy Regulatory Commission's ("FERC" or "Commission") Integrated Licensing Process (ILP). Based on the ILP regulations and the Process Plan and Schedule provided in the PAD, FERC issued Scoping Document 1 on August 10, 2021, and subsequently conducted daytime and evening virtual Scoping Meetings on September 9, 2021. Additionally, during the afternoon of September 9, 2021, GLHA hosted a virtual environmental site review, which provided stakeholders with a comprehensive overview of the Projects utilizing drone video, photographs, and PowerPoint slides. Open question-and-answer sessions were held during FERC's daytime scoping meeting, as well as following the Project presentation during the virtual site review. GLHA notes that during the two question-and-answer sessions, all participants were encouraged to provide comments and to ask any questions regarding the Projects, and neither session was concluded until meeting participants had no further comments or questions.

Following the scoping meetings, several entities filed letters requesting that GLHA provide additional information and that FERC grant a 90-day extension of time, following GLHA's providing of the additional information, to file study requests and comments on the PAD. These entities included the National Marine Fisheries Service (NMFS) on September 13, 2021, the U.S. Fish and Wildlife Service (USFWS) on September 14, and the Penobscot Indian Nation (PIN) and Trout Unlimited (TU), both on September 16. Specifically, all entities requested that GLHA provide copies of study reports for each previously completed study referenced in the PAD and provide 10 years of operations data for each Project including: 1) daily impoundment elevations; and 2) daily outflows for each Project (minimum, maximum, and average daily discharge).

Fax: 207.723.3948

**Integrated Licensing Process**

The ILP was established by Commission Order No. 2002 on July 23, 2003 and marked a major reform of hydropower licensing. As noted in the introduction to the rule, the changes created by the ILP "are the culmination of efforts by the Commission, other Federal and state agencies, Indian tribes, licensees, and members of the public to develop a more efficient and timely licensing process, while ensuring that licenses provide appropriate resource protections required by the Federal Power Act (FPA) and other applicable laws." The Commission adopted the ILP following a long and deliberative rulemaking process that addressed comments from the Departments of the Interior and Commerce, as well as Trout Unlimited.

As explained in Order No. 2002, the ILP was established as the default licensing process specifically to address large projects with both complexity of resource issues as well as with a reasonable anticipation of controversy. The ILP and its associated schedule of activities, therefore, was expressly designed to accommodate projects exactly like the Ripogenus and Penobscot Mills Projects. However, GLHA contends that the Ripogenus and Penobscot Mills Projects are by no means exceptional in size or complexity when considered in the context of other hydropower projects licensed by the Commission since the ILP was introduced. Further, 30-year licenses for these Projects were issued on October 22, 1996. The imminent expiration of these licenses has been well known and remarked upon within the state by agencies and NGOs alike.

In preparing for filing the Notices of Intent and PAD on June 11, GLHA carefully considered the most appropriate process for relicensing these Projects before selecting the ILP. GLHA spent considerable resources developing a PAD that was as clear and comprehensive as possible in order to facilitate stakeholder review, and GLHA filed these materials as early as it could in order to ensure the Director's Study Determination would be issued in time to allow for a full 2022 study season.

**Request for Sources**

Regarding the request for the source study information, GLHA's June 11, 2021, PAD meets the applicable regulatory requirements as defined by 18 Code of Federal Regulations (CFR) §5.6(d)(3)(i)(B) by including *"summaries (with reference to sources of information or studies) of existing data or studies regarding the resource.*"

In addition, the Commission's regulations have long recognized the need for stakeholders to have access to key information associated with a licensing process. In an ILP, this access is described at 18 CFR §5.2(a), under "Document Availability," as well as §5.6(c)(2), under "Pre-Application Document." Both sections require GLHA to make available for public review both the PAD itself as well as the "sources of information on the existing environment and known or potential resource impacts." As noted in the Notices of Intent, copies of the PAD are located at the offices of Brookfield Renewable at 150 Main Street, Lewiston, Maine 04240 and 1024 Central Street, Millinocket, Maine 04462. However, COVID-19 restrictions currently limit GLHA's ability to provide in-person public access to these materials.

That said, the ILP regulations contemplate other means to provide stakeholder access to source materials used in development of the PAD. Per §5.6(c)(2), "A potential applicant must provide the requested information within 20 days from receipt of the request." The ILP, therefore, already includes provisions to cover requests exactly like those made by stakeholders for the Ripogenus and Penobscot Mills Projects, including a defined timeline.

GLHA notes that all stakeholders have had since the filing of the PAD on June 11 to request copies of the reports. Nonetheless, and consistent with the Commission's regulations, GLHA anticipates filing electronic versions of the requested study reports with the Commission for access by interested parties within 20 days of the earliest such request, which was received on September 13. Upon filing, GLHA will inform stakeholders of the availability of the documents.

**Information Requests**

Regarding the request for 10 years of operational data for each Project, GLHA's June 11, 2021, PAD meets the applicable regulatory requirements as defined by 18 CFR §5.6(d)(2)(v)(B) by including *"a* summary of project generation and outflow records for the five years preceding filing of the pre-application document."

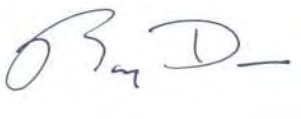
GLHA believes that the requests for operational data are beyond the intent of 18 CFR §5.6(c)(2) or an Additional Information Request at this stage in the relicensing process. Therefore, GLHA believes that such a request should be the subject of a study request through the Commission's ILP.

**Extension Request**

GLHA does not support the request for a 90-day extension of time for parties to file study requests and to provide comments on the PAD for the following reasons:

- The Projects are being relicensed using the Commission's established ILP, which is designed to provide a predictable, efficient, and timely process for large and complex projects such as the Ripogenus and Penobscot Mills Projects.
- The ILP incorporates numerous opportunities for parties to request information or studies and provide comments, including comments on the Proposed Study Plan and Revised Study Plan. There is nothing unique about these Projects to support the Commission altering the established Process Plan and Schedule.
- GLHA filed the PAD on June 11, 2021, which provides a period of approximately 120 days for participants to review the PAD and then file study requests and comments.
- A 90-day extension in the relicensing process would have detrimental effects on the timing and effectiveness of the subsequent relicensing schedule milestones. For example, the current Process Plan and Schedule results in FERC's issuance of a Study Plan Determination by April 22, 2022, which, although a tight timeframe, provides GLHA with sufficient time to prepare for and perform the first season studies in 2022. If the schedule is delayed by 90 days, FERC's Study Plan Determination would be issued on or about July 21, 2022, which would not allow sufficient time to prepare for and perform field studies in 2022. Therefore, the majority of, if not all, of the first season

studies would be delayed until 2023, with potential second season studies then not performed until 2024. Thus, a 90-day time extension would effectively delay the field study component of these relicensings by a full year, thereby severely limiting the time available to incorporate the study results into the relicensing proceedings. In addition, if any studies were to be required in 2024, the associated study results and reports would not be available to the parties during their review of the Draft License Application, which is to be filed by GLHA on or about May 3, 2024, or at the time of the filing of the Final License Application on or before September 30, 2024.



**Additional Scoping Meetings**

Both NMFS and the PIN claim that the Commission should "re-do" the scoping meetings because the format was different from prior scoping sessions. GLHA disagrees and appreciates the Commission's efforts to conduct *any* scoping given the extreme challenges of the COVID-19 pandemic. GLHA notes that up until recently, the Commission has been forced to conduct purely paper scoping that did not afford either Commission staff or the applicant the ability to respond in real-time to stakeholder questions or comments. The PIN asserts that speakers at the public session were somehow disadvantaged by being unable to hear comments made by other speakers. Brookfield notes that, as clearly explained by Commission staff, court reporters recorded all comments provided during the public session and, as with all Commission scoping, transcripts will be available for public review. Finally, Brookfield notes that the period for written comments is still open.

In conclusion, GLHA is committed to expeditiously providing copies of the existing and available study reports for the previously completed studies referenced in the PAD. However, for the reasons outlined above, GLHA does not support the requested 90-day extension of time to file study requests and to provide comments on the PAD. Additionally, GLHA does not support additional scoping meetings at this time.

If you have any questions regarding this information, please contact the undersigned at (207) 775-5605 or randy.dorman@brookfieldrenewable.com.

**RE: Extension of Time Request for the Ripogenus Hydroelectric Project (FERC No. 2572) and Penobscot Mills Hydroelectric Project (FERC No. 2458)**

Dear Secretary Bose:

On September 10, 2021, Maine Department of Inland Fisheries and Wildlife (MDIFW) staff attended the virtual Scoping Meeting hosted by the Federal Energy Regulatory Commission (FERC) for both the Ripogenus Hydroelectric Project (FERC No. 2572) and Penobscot Mills Hydroelectric Project (FERC No. 2458). The Projects are located on the West Branch of the Penobscot River and Millinocket Stream in Piscataquis and Penobscot Counties, Maine.

During the meeting, stakeholders noted that, to date, Great Lakes Hydro America, LLC (GLHA; Applicant) had not provided (1) studies referenced in the Pre-Application Document (PAD); or (2) operations data for any of the projects. In the PAD the Applicant states *"…GLHA maintains that a full suite of new studies is not needed, that the vast body of information on which today's certifications and licenses are soundly based and should be relied upon for these relicensings. In addition, consistent with the Commission's criteria for study requests, the scope and extent of any new study be focused on addressing specific data gaps necessary to inform the development of license requirements."*

While broad summaries of the studies performed during the last relicensing were provided in the PAD, a refined synthesis of the data was not, nor were any data gaps identified by the Applicant. Without the original studies, and without operations data for each dam, stakeholders cannot identify existing data gaps to inform their respective Study Requests or their PAD comments. Therefore, our Agency respectfully requests that FERC require the Applicant to provide stakeholders with ten years of operations data for each Project including, but not limited to, daily impoundment elevation and daily outflows for each project (minimum, maximum, and average daily discharge). We also request that FERC require the Applicant to provide stakeholders with each study referenced in the PAD and that the Commission grant a 90-day extension of time, from when studies and operations data is received, to submit PAD comments and Study Requests for the Ripogenus and Penobscot Mills relicensing proceeding.

Benjamin Koehler, Orono, ME.
Hello, I am writing today to express to FERC my desire for there to be a flow study ordered for Dryway section of the West Branch of the Penobscot (Upstream of McKay Station), and the Backbend (A de watered section downstream of Quakish Lake, upstream of Dolby Pond.  Both of these sections contain quality whitewater recreation, but are not given any recreational flow under current operation of the Ripogenus Hydroelectric Projects.  I believe there the new FERC license should include recreational releases on these sections to better support the betterment of Maine peoples quality of life thru recreation, and to stimulate our struggling local economy.

Thank you
-Benjamin Koehler

Joshua Firmin, Brewer, ME.
Regarding the selected dockets, I am writing to request flow studies to evaluate recreational opportunities.

Thank you.

Tom S Janelle, Falmouth, ME.
Ripogenus Hydroelectric Project nos. P-2572-133.  Docket Number P-2572 Sub Docket - 133

I am writing to voice concerns regarding the water levels and safe, reliable recreational access to Caribou, Chesuncook and Ripogeneous Lakes.  The draw down that occurs on these lakes has made it unsafe to launch boats from both the Caribou Lake put in and the Chesuncook Boat Launch.  My family owns a camp on Caribou Lake ( T3, R12) and we have been unable to safely access the lake from our camp all summer due to these consistent draw downs. Our access to the lake for swimming, fishing and boating/kayaking has been dangerous due to the exceptionally low water levels.

I am also concerned about the ecological impact these large and consistent draw downs have on the water quality of Caribou Lake. the changes that I am seeing to the shoreline of Caribou Lake is disturbing. Plant and tree growth in areas where it should not be happening because of low water levels.  I am worried that without stable water levels these changes will have lasting and profound impact on the wildlife in the area.

I wish to advocate for minimum, stable lake levels with a maximum 1.5 feet draw down from ice out through early September.  This would assure reliable and safe access to the lake for camp owners and the public.  This draw down of 1.5 feet during the summer months is similar to the other lakes in the region, namely the North Twin Development.

Alec Jansujwicz, Bangor, ME.
I am writing to express my interest in a flow study on the Dryway above McKay station and the Backbend sections of the West Branch. As a whitewater paddler, I hope that the recreational opportunity of the Dryway is realized and flows be determined. While Gorge-Crib is one of the best runs in the East, having the extra milage of the Dryway would allow paddlers to experience an entirely new and amazing section of whitewater. Thanks!

Karl Koehler, Orono, ME.
I request flow study on the Dryway and Backbend sections of the West Branch of the Penobscott River.

**Subject:** **Ripogenus Hydroelectric Project (FERC No. 2572-133)**
**Penobscot Mills Hydroelectric Project (FERC No. 2458-247)**
**Supplemental Information – Source Information and Existing Studies**

Dear Secretary Bose:

Great Lakes Hydro America, LLC (GLHA), a subsidiary of Brookfield Renewable and Licensee of the Ripogenus Hydroelectric Project and Penobscot Mills Hydroelectric Project (collectively referred to as the "Projects"), herein files a summary of the source information and existing studies that GLHA is uploading to the Federal Energy Regulatory Commission's ("FERC" or "Commission") eLibrary system. The documentation being uploaded by GLHA provides the source information and available reports for each previously completed study as referenced in the Pre-Application Document (PAD). As indicated in the letter filed with FERC by GLHA on September 17, 2021, GLHA is uploading this information in accordance with 18 Code of Federal Regulations (CFR) §5.6(c)(2) and in response to the stakeholder requests listed below.

- National Marine Fisheries Service letter filed September 13, 2021
- U.S. Fish and Wildlife Service letter filed September 14, 2021
- Maine Council of Trout Unlimited letter filed September 16, 2021
- Penobscot Indian Nation letter filed September 16, 2021
- Maine Department of Marine Resources letter filed September 17, 2021
- Maine Department of Inland Fish and Wildlife letter filed September 17, 2021

On June 11, 2021, GLHA filed the Notices of Intent and PAD, which initiated the relicensing proceeding to obtain two separate new licenses for the continued operation of the Projects through the Commission's Integrated Licensing Process (ILP). Based on the ILP regulations and the Process Plan and Schedule provided in the PAD, FERC issued Scoping Document 1 on August 10, 2021, and subsequently conducted daytime and evening virtual Scoping Meetings on September 9, 2021. Additionally, during the afternoon of September 9, 2021, GLHA hosted a virtual environmental site review, which provided stakeholders with an overview of the Projects utilizing drone video, photographs, and PowerPoint slides. Open question-and-answer sessions were held during FERC's daytime scoping meeting, as well as following the Project overview during the virtual site review.

This letter provides a roadmap of the milestones associated with the previous relicensing of the Projects, as well as the documents that contain copies of the source information and study reports of the previously completed studies. Parties with interest in the requested source information and study reports can download an electronic copy of these documents from FERC's eLibrary system at

Fax: 207.723.3948

https://www.ferc.gov/docs-filing/elibrary.asp by conducting a search using the docket numbers P-2458 and/or P-2572.

## Previous Relicensing Process Milestones

The information provided in the table below indicates primary milestones associated with the previous relicensing of the Projects and is a reference point to the existing information available for these Projects, including studies performed by the Licensee in support of the 1991 License Applications, as well as in response to requests for additional information subsequent to the 1991 filing.

| Date | Milestone |
|---|---|
| 1968 | FERC issued original licenses to Projects, which expired on 12/31/1993. |
| Dec 17, 1991 | Licensee filed separate License Applications for Projects (Volumes I – XII)*. |
| Jun 8, 1992 | FERC issued request for additional information. |
| Jul 1, 1992 | FERC issued amendment to (6/8/1992) request for additional information. |
| Dec 7, 1992 | Licensee filed response to FERC's (6/8/1992) request for additional information (Volume XIII)*. |
| Mar 25, 1993 | FERC issued Notice of Applications Ready for Environmental Analysis. |
| Apr 22-23, 1993 | State of Maine issued Water Quality Certificates for Projects. |
| May 1993 | Agencies and Intervenors filed comments. |
| Jul 8, 1993 | Licensee filed responses to (May 1993) comments filed by Agencies and Intervenors (Volume XIV)*. |
| Oct 28, 1993 | FERC issued request for additional information. |
| Nov 29, 1993 | Licensee filed responses to FERC's (10/28/1993) request for additional information (Volume XV)*. |
| Dec 31, 1993 | Original licenses expired; FERC issued annual licenses until new licenses were issued in 1996. |
| Jan 14, 1994 | FERC issued request for additional information. |
| Feb 14, 1994 | Licensee filed response to FERC's (1/14/1994) request for additional information*. |
| Apr 5, 1994 | Licensee filed refinement to responses previously filed on 11/29/1993 and 2/14/1994*. |
| Dec 1, 1994 | FERC issued Draft Environmental Impact Statement (EIS) for Projects. |
| Jan 25, 1995 | FERC held public hearing in Millinocket, ME. |
| Feb 22, 1995 | Licensee and stakeholders filed comments on Draft EIS. |
| Mar 17, 1995 | Licensee filed response to comments on Draft EIS filed by Agencies and Intervenors*. |
| Oct 1, 1996 | FERC issued Final EIS. |
| Oct 22, 1996 | FERC issued new licenses for Projects. |

*Documents eFiled with FERC as part of this submittal.

## Summary of Studies Performed to Date for Ripogenus Project

The information provided in the table below is a summary of the studies and monitoring performed at the Ripogenus Project prior to the previous relicensing, during the previous relicensing, or after issuance of the new license in 1996. This table also describes the location of where this information can be found, the majority of which is being filed with FERC as part of this submittal or is otherwise readily available on FERC's eLibrary.

| Resource | Study | Date | Comments | Location of Information |
|---|---|---|---|---|
| **Water Quality and Quantity** | Water Quality Study | 1977, 1978, 1980 | Pre-relicensing studies. | Summary of results provided in Ripogenus License Application, Vol 2. |
| | Water Quality Study | 1981 | Pre-relicensing studies. | Summary of results provided in Ripogenus License Application, Vol 2. |
| | Water Quality Study | 1982, 1983, 1984 | Additional pre-relicensing studies to compliment previous studies. | Summary of results provided in Ripogenus License Application, Vol 2. |
| | Water Quality Study | 1986, 1987 | Two complete years of data collected in Upper Gorge, McKay Station Tailrace, Ripogenus Lake, Caribou Lake, Ragged Lake Stream (inlet to Caribou Lake), Chesuncook Lake (3 locations), West Branch (inlet to Chesuncook Lake), Caucomgomoc Stream flowage/Black and Brand Ponds. | Summary of results provided in Ripogenus License Application, Vol 2 with data provided in Appendix E2 II-1 (Vol 7). |
| | Water Quality Study | 1988 | Less extensive study to supplement 1986-1987 studies with data collected at McKay Station Tailrace, Ripogenus Lake, Caribou Lake, and Chesuncook Lake (2 locations). | Summary of results provided in Ripogenus License Application, Vol 2 with data provided in Appendix E2 II-2 (Vol 7). |
| | Water Quality Modeling Evaluation of Downstream Impacts Associated with Run-of-River Flow Management | 1991 | Evaluation of water quality (dissolved oxygen) implications of changing the existing West Branch storage projects to run-of-river operation through use of Qual2E model for riverine systems. | Summary of results provided in Ripogenus License Application, Vol 2 with study report contained in Appendix E2-V-3 (Vol 7). |
| | VLMP Water Quality Monitoring in Chesuncook Lake | 2001 | Water quality data collected by Volunteer Lake Monitoring Program. | Publicly available data via: https://www.lakesofmaine.org/lake-water-quality.html?m=0662 |
| | Derivation of 7Q10 Value for West Branch | 1987 | Study conducted by Kleinschmidt Associates. | Summary of results provided in Ripogenus License Application, Vol 2 with study report contained in Appendix E2-V-1 (Vol 7). |
| | Natural Inflow Study in Penobscot River Basin Upstream of East Millinocket Dam | 1990 | Study performed by Stone & Webster Engineering Corporation, which examines the natural inflow into the Projects in support of assessing the impacts of the consequences of an operational change that would eliminate the drawdown of the Project's impoundments. | Summary of results provided in Ripogenus License Application, Vol 2 with study report contained in Appendix E2-V-2 (Vol 7). |
| | Water Use Plan Modeling | 1991 | Licensee developed the Water Use Plan, which was a model of its entire system to determine whether Project operations could be adjusted to satisfy agency mitigation/enhancement requests. | Summary of results provided in Ripogenus License Application, Vol 2 with study report contained in Appendix E2-V-3 (Vol 7). |
| | Use Attainability Analysis | 1992 | MDEP Use Attainability Analysis to support the change in classification of the Ripogenus Impoundment. | UAA provided in 47-page letter dated October 26, 1992 from MDEP to USEPA. |

| Resource | Study | Date | Comments | Location of Information |
|---|---|---|---|---|
| **Aquatic Resources** | Aquatic Community Study | 1981, 1982, 1984, 1986, 1987 | Reports on Periphyon, Phytoplankton, Zooplankton, and Benthic Macroinvertebrates in the Ripogenus Project area. | Summary of results provided in Ripogenus License Application, Vol 2 with study reports contained in Appendix E3.1 V-1 (Vol 8). |
| | 1990 Report on Studies of the Habitat, Fish Populations, and Fisheries of the Ripogenus Project | Various | Report summarizes results the studies listed below:<br>• 1960 MDIFW Chesuncook Lake Survey<br>• 1986 MDIFW Chesuncook Lake Progress Report No. 1<br>• Study Area Stocking Records<br>• 1978-1989 Summary of Individual River Section Creel Census Data in West Branch (McKay Station to Ambajejus Lake)<br>• 1984-1989 Estimates of Smelt Drift at Holbrook Pool and Horserace in West Branch<br>• 1989 Upper Gorge Habitat Base Flow Study | Summary of results provided in Ripogenus License Application, Vol 2 and Appendix E3.1 V-1 (Vol 9) with study reports for supporting studies provided in Appendix E3.1 V-2 (Vol 10) |
| | Smelt Access to Spawning Streams (14) | 1987, 1988 | Evaluation of rainbow smelt access to potential spawning tributaries in Ripogenus impoundment. | A summary of the results is provided in Ripogenus License Application, Vol 2 and detailed descriptions are provided in Appendix E3.1-V-1 and E3.1-V2 *Report on Fish Resources* (Vol 9 and 10). |
| | Angler Creel Census | 1987, 1988 | GHLA completed interviews by boat, at boat launches, or at camps to estimate angling use, catch, and harvest. | A summary of the results is provided in Ripogenus License Application, Vol 2 and detailed descriptions are provided in Appendix E3.1-V-1 and E3.1-V2 *Report on Fish Resources* (Vol 9 and 10). |
| | MDIFW Winter Creel Census | 1986 | Intensive creel surveys completed by MDIFW in response to increased angling pressure. | A summary of the results is provided in Ripogenus License Application, Vol 2 and detailed descriptions are provided in Appendix E3.1-V-1 and E3.1-V2 *Report on Fish Resources* (Vol 9 and 10). |
| | Fisheries Study in 19 Tributaries to Ripogenus Impoundment | 1986-1989 | Electrofishing, salmon redd surveys, trap-net surveys, and habitat assessments to document baseline conditions in 19 tributaries to Ripogenus Lake. | A summary of the results is provided in Ripogenus License Application, Vol 2 and detailed descriptions are provided in Appendix E3.1-V-1 and E3.1-V2 *Report on Fish Resources* (Vol 9 and 10). |
| | Holbrook Side Channel Baseline Fishery Survey | 1997-1998 | Baseline monitoring performed prior to modification of side channel. | FERC eLibrary (filed 12/31/1998). |

| Resource | Study | Date | Comments | Location of Information |
|---|---|---|---|---|
| | Holbrook Side Channel Improvement Monitoring and Reporting | 1998, 1999, 2000, 2001, 2002 | Modifications completed in Sep 1998. Monitoring performed and reported to FERC. | FERC eLibrary (filed 12/28/1999, 1/8/2001, 1/15/2002, 1/23/2003). |
| | Mercury Monitoring | 1997-1998 | Sediment and water samples were collected from Chesuncook Lake, Lower Dolby Pond, and Seboeis Lake and analyzed for mercury. Fish were collected at Chesuncook and Seboeis Lakes, North Twin impoundment, and the West Branch (downstream of Ripogenus Dam) and analyzed for mercury. Fish previously collected from Dolby Pond and Lobster Lake and analyzed for mercury were included in this study. | FERC eLibrary (filed 6/1/1999). |
| **Wildlife, Botanical, Wetlands** | Botanical Resource Assessment | 1981 | Pre-relicensing study of 4-mile section of West Branch and T-line corridor from McKay Station to Millinocket. | Summary of results provided in Ripogenus License Application, Vol 2. |
| | Botanical and Wildlife Resource Assessment | 1986, 1987, 1989, 1991 | Study area includes Ripogenus impoundment, Upper Gorge, 21-mile-long segment of West Branch, and 30-mile-long transmission corridor from McKay Station to Millinocket. | Summary of results provided in Ripogenus License Application, Vol 2 with study data in Vol 10. |
| | Wetland Enhancement Assessment | 1992 | Study performed in response to June 8, 1992 FERC AIR #6. Study identified possible wetland enhancement sites: north end of impoundment on Black Pond and at mouth of Quaker Brook. | Study report/results filed in Licensee's December 7, 1992 Response to AIRs (Vol 13 of Ripogenus License Application). |
| | Observation of Wildlife Habitat Value of West Branch Deadwater Wetlands under Existing and Unmanaged Flow Conditions | 1992 | Study performed in response to June 8, 1992 FERC AIR #6. | Study report/results filed in Licensee's December 7, 1992 Response to AIRs (Vol 13 of Ripogenus License Application). |
| | Umbazooksus Lake Wetland Enhancement Monitoring and Reporting | 1998, 2000, 2002, 2004 | Baseline monitoring performed in 1998 prior to wetland enhancement measures at Umbazooksus Lake. Monitoring and reporting performed in 2000, 2002, and 2004 to evaluate wetland enhancement measures. | FERC eLibrary (filed 6/3/1999, 6/4/2001, 6/13/2003, 6/20/2003, 6/1/2005). |
| | Loon Nesting Annual Monitoring and Reporting | 1998 through 2010 | Artificial nesting platforms deployed annually through license term; monitoring and reporting conducted annually from 1998-2010. | FERC eLibrary (Final Annual Report filed on 10/19/2010). |
| **Recreation** | Recreation Facility Inventory | ~1990 | Study data provides detailed information about Project and non-Project recreation facilities in vicinity of Ripogenus Project. | Summary of results provided in Ripogenus License Application, Vol 3 with study data provided in Appendix E5-II (Vol 11). |
| | Whitewater Boating and | 1990 | Surveys performed along West Branch downstream of McKay | Summary of results provided in Ripogenus License Application, |

| Resource | Study | Date | Comments | Location of Information |
|---|---|---|---|---|
| | Angling Use Survey | | Station from June through September 1990. | Vol 3 with study data provided in Appendix E5-V (Vol 11). |
| | Whitewater Boating Additional Information | 1992 | Response to June 8, 1992 FERC AIR #17 and 18 providing additional information related to requested and licensee-proposed whitewater boating flows. | Summary of results provided in Licensee's December 7, 1992 Response to AIRs (Vol 13 of Ripogenus License Application). |
| | Recreation Use and Needs Monitoring and Reporting | 2001, 2008, 2014 | Monitoring was performed May thru Sep every 6 years at Project boat launches and picnic areas. MDOC provided use data on campsites managed by MDOC. | FERC eLibrary (filed 10/24/2002, 1/29/2009, 4/28/2015). |
| **Cultural** | Phase 0 Cultural Resource Assessment | 1988 | | Study report provided in Ripogenus License Application, Vol 12 (Non-public information). |
| | Archaeological Phase I Survey and Phase II Testing | 1989, Supplemented 1991 | | Study reports provided in Ripogenus License Application, Vol 12 (Non-public information). |
| | Phase III Mitigation Activities and Annual Reporting | 1998 through current | Reports filed annually in October with FERC. | FERC eLibrary (Non-public information). |
| **Visual** | Visual Resources Study | 1990 | Study performed by Dewan and Associates that describes and analyzes visual resources and activities within the Ripogenus Project study area. | Summary of results provided in Ripogenus License Application, Vol 3 with study data provided in Appendix E6-V (Vol 11). |

## Description of 1991 License Application for Ripogenus Project

The information in the table below provides a detailed overview of the contents of the Ripogenus Project License Application filed in December 1991 as well as subsequent filings by the Licensee providing responses to additional information requests by FERC and comments from stakeholders. The documents listed in the table below are being filed with FERC as part of this submittal, unless otherwise indicated. Additionally, as noted in the table below, some of these documents are considered non-public as they contain Controlled Unclassified Information (CUI) as either Privileged Information or Critical Electric/Energy Infrastructure Information (CEII) and are filed as such as part of this submittal.

| Volume No. | Content | Description |
|---|---|---|
| I | Exhibit A | Project Description |
| | Exhibit B | Project Operation and Resource Utilization |
| | Exhibit C | Construction History |
| | Exhibit D | Project Costs |
| | Exhibit F | Project Works Drawings (CEII / Non-Public Information) (see Vol IV) |
| | Exhibit G | Project Boundary Drawings |
| II | Exhibit E | Environmental Report |
| | Section 1.0 | General Description of Locale |
| | Section 2.0 | Report on Water Use and Quality |
| | Section 3.1 | Report of Fish Resources |

| Volume No. | Content | Description |
|---|---|---|
| | Section 3.2 | Report on Botanical Resources |
| | Section 3.3 | Report on Wildlife Resources |
| III | Exhibit E | Environmental Report |
| | Section 4.0 | Report on Historical/Archaeological Resources |
| | Section 5.0 | Report on Recreational Resources |

| | AIR #2 | Wetlands Enhancements – Additional Supporting Information |
| | AIR #3 | Back Channel IFIM – Additional Information |
| | AIR #4 | Evaluation of Generating Facilities at Stone Dam |
| | AIR #5 | Evaluation of Economic Impact of Change in Operations |
| -- | Feb 14, 1994 | Licensee response to FERC's (1/14/1994) request for additional information |
| | 1 | Flow Impacts (Upper Gorge; Outage Flows, Whitewater Flows, Spawning Flows; Millinocket Stream) |
| | 2 | Spreadsheet Results for Driest and Worst Case "Typical" Year |
| | 3 | Spreadsheet Results Showing Effect on Impoundment Elevations and Minimum Flows for Average, Driest, Wettest, and "Typical" Years |
| | 4 | Average Annual Costs for flows in Upper Gorge, Millinocket Stream, and Back Channel |
| -- | Apr 5, 1994 | Licensee refinement to 11/29/1993 and 2/14/1994 responses |
| -- | Mar 17, 1995 | Licensee response to (2/22/1995) comments on Draft EIS |

## Summary of Studies Performed to Date for Penobscot Mills Project

The information provided in the table below is a summary of the studies and monitoring performed at the Penobscot Mills Project prior to the previous relicensing, during the previous relicensing, or after issuance of the new license in 1996. This table also describes the location of where this information can be found, the majority of which is being filed with FERC as part of this submittal or is otherwise readily available on FERC's eLibrary.

| Resource | Study | Date | Comments | Location of Information |
|---|---|---|---|---|
| **Water Resources** | Water Quality Study | 1981 – 1985 | Licensee performed annual summer river surveys related to their licensed wastewater discharges and performed water quality measurements in support of biomonitoring studies. | Summary of results provided in Penobscot Mills License Application, Vol 2. |

| Resource | Study | Date | Comments | Location of Information |
|---|---|---|---|---|
| | MDEP Water Quality Study | 1984-1985 | MDEP performed water quality measurements as part of effluent discharge modeling efforts. | Summary of results provided in Penobscot Mills License Application, Vol 2 with the study report provided in Appendix E2-V-3 (Vol 7). |
| | Water Quality Study | 1986, 1987 | Licensee performed two complete years of data collection in all major impoundment/lake basins and tailrace waters (total of 17 locations). | Summary of results provided in Penobscot Mills License Application, Vol 2 with data provided in Appendix E2 II-1 (Vol 7). |
| | Water Quality Study | 1988 | Licensee performed less extensive study to supplement 1986-1987 studies with data collected at a total of 12 locations. | Summary of results provided in Penobscot Mills License Application, Vol 2 with data provided in Appendix E2 II-1 (Vol 7). |
| | MDEP West Branch Penobscot Waste Load Allocation | 1987 | Evaluation of water quality impacts from industrial and municipal point sources and historic accumulations of sludge in impoundments through use of Qual2E model for riverine systems. | Summary of results provided in Penobscot Mills License Application, Vol 2 with study report contained in Appendix E2-V-3 (Vol 7). |
| | Derivation of 7Q10 Value for West Branch | 1987 | Study conducted by Kleinschmidt Associates. | Summary of results provided in Penobscot Mills License Application, Vol 2 with study report contained in Appendix E2-V-1 (Vol 7). |
| | Water Quality Modeling Evaluation of Downstream Impacts Associated with Run-of-River Flow Management | 1991 | Evaluation of water quality (dissolved oxygen) implications of changing the existing West Branch storage projects to run-of-river operation through use of Qual2E model for riverine systems. | Summary of results provided in Penobscot Mills License Application, Vol 2 with study report contained in Appendix E2-V-4 (Vol 7). |
| | Natural Inflow Study in Penobscot River Basin Upstream of East Millinocket Dam | 1990 | Study performed by Stone & Webster Engineering Corporation, which examines the natural inflow into the Projects in support of assessing the impacts of the consequences of an operational change that would eliminate the drawdown of the Project's impoundments. | Summary of results provided in Penobscot Mills License Application, Vol 2 with study report contained in Appendix E2-V-2 (Vol 7). |
| | Water Use Plan Modeling | 1991 | Licensee developed the Water Use Plan, which was a model of its entire system to determine whether Project operations could be adjusted to satisfy agency mitigation/enhancement requests. | Summary of results provided in Penobscot Mills License Application, Vol 2 with study report contained in Appendix E2-V-5 (Vol 7). |
| | Water Quality Assessment of Back Channel | 1992 | Conducted in response to FERC's June 8, 1992 AIR. | Study results provided in Licensee's December 7, 1992 response to AIRs (Vol 13 of Penobscot Mills License Application). |
| | PIN Water Quality Studies | 2012-2019 | Water quality data collected in the West Branch Penobscot River by the Penobscot Indian Nation. | Publicly available data via: https://www.waterqualitydata.us/provider/STORET/ |

| Resource | Study | Date | Comments | Location of Information |
|---|---|---|---|---|
| | | | | PENOBSCOTINDIANNATIONDNR/ |
| | VLMP Water Quality Monitoring in North Twin and Millinocket Lake Storage Impoundments | 2007-2011 | Water quality data collected by Volunteer Lake Monitoring Program. | Publicly available data via: https://www.lakesofmaine.org/ data/2018_Lake_Reports/982_6.html<br><br>https://www.lakesofmaine.org/ data/2018_Lake_Reports/2020_1.html |
| | MDEP Water Quality Study of West Branch and Penobscot River | 2007 | Water quality study conducted by MDEP in West Branch and main stem Penobscot River for calibration and verification of a water quality model. | Publicly available data via: https://www.maine.gov/dep/water/ monitoring/rivers_and_streams/ modelinganddatareports/index.html. |
| | MDEP Biological Monitoring Program Benthic Macroinvertebrate Data | 1984, 1987, 1995, 1996, 2000, 2001, 2006, 2011, 2017 | Benthic macroinvertebrate sampling results from the West Branch and Millinocket Stream. | Publicly available data via: https://www1.maine.gov/ dep/water/monitoring/ biomonitoring/data.html. |
| **Aquatic Resources** | Report on Studies of Aquatic Communities | 1986-1987 | Study performed by Normandeau Associates. Samples collected during ice-free period from North Twin impoundment, Millinocket Lake, Quakish Lake, Dolby Pond, Millinocket Stream, and Back Channel to characterize existing aquatic communities. | Summary of results provided in Penobscot Mills License application, Vol 2 with study report contained in Appendix in Vol 8. |
| | Instream Flow Studies | 1987-1988 | Instream flow studies performed by Normandeau Associates in the Back Channel and Millinocket Stream to determine the minimum flows necessary to maintain aquatic habitat in these two streams. | Study results provided in August 1989 Study Report provided in Appendix Q of Appendix E3.1-V-2 in Vol 10 of Penobscot Mills License Application. |
| | Mercury in Surface Water, Sediment, and Fish from Selected Lakes of Northern Maine | 1992 | Study report prepared by Environmental Science and Engineering, Inc. in response to June 8, 1992 FERC AIR #8. | Study results provided in Licensee's December 7, 1992 Response to AIRs (Vol 13 of Penobscot Mills License Application). |
| | Mercury Monitoring | 1997-1998 | Sediment and water samples were collected from Chesuncook Lake, Lower Dolby Pond, and Seboeis Lake and analyzed for mercury. Fish were collected at Chesuncook and Seboeis Lakes, North Twin impoundment, and the West Branch (downstream of Ripogenus Dam) and analyzed for mercury. Fish previously collected from Dolby Pond and Lobster Lake and analyzed for mercury were included in this study. | FERC eLibrary (filed 6/1/1999). |
| | Millinocket Stream Brook Trout Stocking | Annually 1998-2002 | Annual monitoring and reporting for evaluating the brook trout stocking program in Millinocket Stream. | FERC eLibrary (filed 2/5/1999, 2/3/2000, 2/8/2001, 2/14/2002, 1/29/2003). |

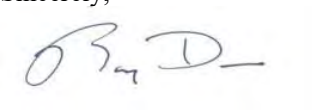
| Resource | Study | Date | Comments | Location of Information |
|---|---|---|---|---|
| | Program Monitoring | | | |
| | North Twin Impoundment Lake Trout Reproduction Monitoring | Biannually from 2000-2010 | Biannual monitoring and reporting to evaluate the reproductive success of lake trout in the impoundment resulting from stable lake elevations. | FERC eLibrary (filed 1/26/2001, 1/28/2003, 1/26/2005, 2/2/2007, 2/4/2009, 1/27/2011). |
| **Wildlife, Botanical, Wetlands** | Botanical and Wildlife Assessment | | Botanical investigations of North Twin impoundment, Quakish Lake, Ferguson Pond, Dolby Pond, East Millinocket impoundment, Millinocket Lake Storage impoundment, Millinocket Stream, segments of the West Branch, Back Channel, and transmission line corridors. Investigations were designed to characterize existing vegetation and wildlife and shoreline environments to evaluate effects of annual drawdowns in water level of the two storage impoundments. | Summary of results provided in Penobscot Mills License Application, Vol 2 with study report provided in Appendix E3.2-II and E3.3-II (Vol 10). |
| | Wildlife Management Plan for Back Channel | 1991 | Report prepared by Normandeau Associations to outline existing wildlife habitat conditions in the Back Channel area and wildlife management practices that may be used to increase the value of the area to wildlife. | Summary of results provided in Penobscot Mills License Application, Vol 2 with study report provided in Appendix E3.3-V (Vol 10). |
| | Wildlife Management Area Monitoring | Annual monitoring with reports filed every 5 years | Monitoring reports filed with the Commission wildlife monitoring reports every 5 years through 2018. | eLibrary (filed 2/8/2000, 2/7/2003, 2/12/2008, 2/12/2013, 2/12/2018). |
| | Wetland Enhancement Assessment | 1992 | Study performed in response to June 8, 1992 FERC AIR #6. Study identified possible wetland enhancement sites at the North Twin impoundment and Millinocket Lake Storage impoundment. | Study report/results filed in Licensee's December 7, 1992 Response to AIRs (Vol 13 of Penobscot Mills License Application). |
| | Observation of Wildlife Habitat Value of West Branch Deadwater Wetlands under Existing and Unmanaged Flow Conditions | 1992 | Study performed in response to June 8, 1992 FERC AIR #6. | Study report/results filed in Licensee's December 7, 1992 Response to AIRs (Vol 13 of Penobscot Mills License Application). |
| | Loon Nesting Annual Monitoring and Reporting | 1998 through 2010 | Annual platform deployment and monitoring from 1998-2010 indicated loons were reproducing naturally at Millinocket Lake Storage impoundment; Platform | FERC eLibrary (Final Annual Report filed on 10/19/2010). |

| Resource | Study | Date | Comments | Location of Information |
|---|---|---|---|---|
| | | | deployment and monitoring ceased in 2010. | |
| **Recreation** | Recreation Use Survey | 1986, 1987 | Study provides information about how different user groups utilize the project impoundments and recreation areas. | Summary of results provided in Penobscot Mills License Application, Vol 3 with copies of survey forms used in Appendix E5-II (Vol 11). |
| | Recreation Facility Inventory | ~1990 | Study data provides detailed information about Project and non-Project recreation facilities in vicinity of Penobscot Mills Project. | Summary of results provided in Penobscot Mills License Application, Vol 3 with study data provided in Appendix E5-II (Vol 11). |
| | Recreation Facility Inventory Supplemental Information | 1992 | Information provided in response to FERC's June 8, 1992 AIRs #19, 20, 21. | Results provided in Licensee's December 7, 1992 Response to FERC AIRs (Vol 13 of Penobscot Mills License Application). |
| | Millinocket Stream Boatability Assessment | 1992 | Information provided in response to FERC's June 8, 1992 AIR #22. | Results provided in Licensee's December 7, 1992 Response to FERC AIRs (Vol 13 of Penobscot Mills License Application). |
| | Recreation Use and Needs Monitoring and Reporting | 2001, 2008, 2014 | Monitoring is performed May thru Sep at Project boat launches and picnic areas. | FERC eLibrary (filed on 10/24/2002, 1/29/2009, 4/28/2015). |
| | Navigation Hazard Study | 2000 | Study to develop a map of navigational hazards at Millinocket Lake Storage and North Twin impoundments. | eLibrary (filed 5/2/2001). |
| **Cultural** | Phase 0 Cultural Resource Assessment | 1988 | | Study report provided in Penobscot Mills License Application, Vol 12 (Non-public information). |
| | Archaeological Phase I Survey and Phase II Testing | 1989, Supplemented 1991 | | Study reports provided in Penobscot Mills License Application, Vol 12 (Non-public information). |
| | Phase III Mitigation Activities | 1998-Current | | FERC eLibrary (Non-public information). |
| **Visual** | Visual Resources Study | 1990 | Study performed by Dewan and Associates that describes and analyzes visual resources and activities within the Penobscot Mills Project study area. | Summary of results provided in Penobscot Mills License Application, Vol 3 with study data provided in Appendix E6-V (Vol 11). |

## Description of 1991 License Application for Penobscot Mills Project

The information in the table below provides a detailed overview of the contents of the Penobscot Mills Project License Application filed in December 1991 as well as subsequent filings by the Licensee providing responses to additional information requests by FERC and comments from stakeholders. The documents listed in the table below are being filed with FERC as part of this submittal, unless otherwise indicated. Additionally, as noted in the table below, some of these documents are considered non-public as they contain Controlled Unclassified Information (CUI) as either Privileged Information or Critical Electric/Energy Infrastructure Information (CEII) and are filed as such as part of this submittal.

| Volume No. | Content | Description |
|---|---|---|
| I | Exhibit A | Project Description |
| | Exhibit B | Project Operation and Resource Utilization |
| | Exhibit C | Construction History |
| | Exhibit D | Project Costs |
| | Exhibit F | Project Works Drawings (CEII / Non-Public Information) (see Vol IV) |
| | Exhibit G | Project Area Drawings |
| II | Exhibit E | Environmental Report |
| | Section 1.0 | General Description of Locale |
| | Section 2.0 | Report on Water Use and Quality |
| | Section 3.1 | Report of Fish Resources |
| | Section 3.2 | Report on Botanical Resources |
| | Section 3.3 | Report on Wildlife Resources |
| III | Exhibit E | Environmental Report |
| | Section 4.0 | Report on Historical/Archaeological Resources |
| | Section 5.0 | Report on Recreational Resources |
| | Section 6.0 | Report on Land Management and Aesthetics |
| | Section 7.0 | Summary of Agency Consultation |
| IV | Exhibit F | Supporting Design Report (CEII / Non-Public Information) |
| V | Exhibit H | Description of Project Management and Need for Power |
| VI | Appendix | Agency and Public Correspondence (Not included in this submittal) |
| VII | Appendix | Report on Water Use and Quality |
| | E2-I | 1986-1988 Water Quality Study Methodology |
| | E2-II-1 | 1986-1987 Water Quality Study Data |
| | E2-II-2 | 1988 Water Quality Data |
| | E2-II-3 | 1988 Sediment Data |
| | E2-III | Water Quality Study Consultation Correspondence (Vol VI) |
| | E2-IV | Water Quality Study Literature Citations |
| | E2-V-1 | 1987 Study Report for Derivation of 7Q10 Value for West Branch |
| | E2-V-2 | 1990 Study Report for Natural Inflow Study in Penobscot River Basin Upstream of East Millinocket Dam |
| | E2-V-3 | 1988 MDEP West Branch Waste Load Allocation |
| | E2-V-4 | Water Quality Modeling Evaluation of Downstream Impacts Associated with Run-of-River Flow Management |
| | E2-V-5 | Water Use Plan for Ripogenus and Penobscot Mills Projects |
| VIII | Appendix | Report on Fish Resources |
| | | 1990 Report on Study of Aquatic Communities |
| IX | Appendix | Report on Fish Resources |
| | E.3-1-V-1 | 1990 Report on Studies of the Habitat, Fish Populations, and Fisheries of the Penobscot Mills Project |
| X | Appendix | Report on Fish Resources (Study Report Appendices) |
| | E3.1-V-2 | Appendices for 1990 Report on Studies of the Habitat, Fish Populations, and Fisheries of the Penobscot Mills Project |
| | A | Data Tables |
| | B | Bathymetric Maps |
| | C | Study Area Stocking Records |
| | D | 1972-1985 North Twin Impoundment Water Level Data (By Spawning Season) |



| Volume No. | Content | Description |
|---|---|---|
| | E | 1972-1985 Millinocket Lake Water Level Data (By Spawning Season) |
| | F | 1972-1985 Quakish Lake Water Level Data |
| | G | 1972-1985 Dolby Pond Water Level Data |
| | H | 1972-1985 Daily Flows in the West Branch Below North Twin Development |
| | I | 1972-1985 Daily Flows in Millinocket Stream |
| | J | 1972-1985 Daily Flows Pumped from Millinocket Lake to North Twin Impoundment |
| | K | 1972-1985 Daily Flows in the West Branch Below Millinocket Station Tailrace |
| | L | 1972-1985 Daily Flows in the West Branch at Shad Pond |
| | M | 1972-1985 Daily Flows in the Back Channel |
| | N | 1976-1985 Natural vs. Historic Flow at North Twin |
| | O | 1976-1985 Natural vs. Historic Flow at Stone Dam |
| | P | 1976-1985 Natural vs. Historic Flow at Dolby/East Millinocket Dams |
| | Q | Instream Flow Studies (Millinocket Stream & Back Channel) |
| | Appendix | Report on Botanical Resources |
| | E3.2-II | Botanical Data |
| | E3.2-III | Consultation Correspondence (Vol VI) |
| | Appendix | Report on Wildlife Resources |
| | E3.3-II | Wildlife Data |
| | E3.3-III | Consultation Correspondence (Vol VI) |
| | E3.3-IV | Literature Cited |
| | E3.3-V | Wildlife Management Plan for the Back Channel |
| XI | Appendix | Report on Historical/Archaeological Resources |
| | Appendix | Report on Recreational Resources |
| | E5-I | Resident and Leaseholder Survey |
| | E5-II | Recreation Data Facility Inventory (provides details of facilities including photographs and number of parking spaces) |
| | E5-III | Consultation Correspondence (see Volume VI) |
| | E5-IV | Literature Cited |
| | | Report on Land Management and Aesthetics |
| | E6-II | Land Use Data MLURC Use Standards |
| | E6-III | Consultation Correspondence (see Volume VI) |
| | E6-V | 1990 Report on Visual Resources |
| XII | Appendix | Archaeology – Correspondence and Reports (Privileged / Non-public Information) |
| | I | Agency Consultation |
| | II | Reports |
| | | 1988 Phase “0” Cultural Resources Assessment of the Penobscot Mills Project |
| | | 1991 Supplemental Archaeological Phase II Testing of the Penobscot Mills Project |
| | | 1991 Archaeological Phase I Survey and Phase II Testing of the Penobscot Mills Project |

| Volume No. | Content | Description |
|---|---|---|
| XIII | Response to AIRs | Licensee response to FERC's June 8, 1992 AIRs (Penobscot Mills Only) |
| | AIR #2 | Back Channel Water Quality |
| | AIR #3 | Details regarding Millinocket Stream Minimum Flow |
| | AIR #5 | Copy of NPDES Permits |
| | AIR #6 | Potential Wetland Enhancement |
| | AIR #7 | Back Channel Wildlife Management Plan |
| | AIR #8 | Mercury Contaminant Study |
| | AIR #9 | Cultural Resources Management Plan |
| | AIR #11 | Future Sites for Recreation Development |
| | AIR #19 | Recreation Facilities Inventory |
| | AIR #20 | Effect of Impoundment Levels on Boat Docks |
| | AIR #21 | Millinocket Stream Whitewater Access |
| | AIR #22 | Millinocket Stream Minimum Canoeable Flow |
| | AIR #23 | Safety Concerns at Great Northern Dams |
| | AIR #24 | Channel Markers on North Twin |
| | AIR #25 | Weekday/Year-round Access to Ambajejus Falls |
| | AIR #26 | Needs of the Disabled |
| | AIR #27 | Upstream Impoundments |
| | AIR #28 | Miscellaneous Consultation |
| XIV | Response to AIRs | Licensee response to Comments by Agencies and Intervenors for Ripogenus and Penobscot Mills Projects |
| | | Penobscot Indian Nation Claims to Islands in West Branch |
| | | Water Quality |
| | | Mercury Bioaccumulation – Water Quality |
| | | Mercury Bioaccumulation – Endangered Species |
| | | Millinocket Stream Minimum Flows |
| | | Fish Passage |
| | | Upper Gorge Minimum Flows |
| | | Minimum Flows below McKay Station |
| | | Minimum Flows in Back Channel |
| | | Impoundment Operations – Drawdown Limitations |
| | | Impoundment Operations – Run-of-River |
| | | Use of Herbicides on Transmission Line Rights-of-Way |
| | | Water Use Plan |
| | | Recreation Issues |
| | | Comprehensive Water Basin Issues |
| | | Buffer Zones |
| | | Energy Conservation |
| | | Power Generation Alternatives |
| | | Mill Economics and Employment |
| | | Response to Specific Agency and Indian Tribe Recommendations |
| | | Conclusion |
| XV | Response to AIRs | Licensee response to FERC's October 28, 1993 AIRs |
| | AIR #1 | Water Use Plan Model – Supporting Documentation |
| | AIR #2 | Wetlands Enhancements – Additional Supporting Information |
| | AIR #3 | Back Channel IFIM – Additional Information |
| | AIR #4 | Evaluation of Generating Facilities at Stone Dam |
| | AIR #5 | Evaluation of Economic Impact of Change in Operations |
| -- | Response to AIRs | Licensee response to FERC's (1/14/1994) request for additional information |

| Volume No. | Content | Description |
|---|---|---|
| | 1 | Flow Impacts (Upper Gorge; Outage Flows, Whitewater Flows, Spawning Flows; Millinocket Stream) |
| | 2 | Spreadsheet Results for Driest and Worst Case "Typical" Year |
| | 3 | Spreadsheet Results Showing Effect on Impoundment Elevations and Minimum Flows for Average, Driest, Wettest, and "Typical" Years |
| | 4 | Average Annual Costs for flows in Upper Gorge, Millinocket Stream, and Back Channel |
| -- | Response to AIRs | Licensee refinement to 11/29/1993 and 2/14/1994 responses |
| -- | Response to Comments on Draft EIS | Licensee response to (2/22/1995) comments on Draft EIS |

FEDERAL ENERGY REGULATORY COMMISSION
Washington, DC 20426
September 28, 2021

OFFICE OF ENERGY PROJECTS

Project Nos. 2572-133 & 2458-247 –
Maine
Ripogenus Hydroelectric Project
Penobscot Mills Hydroelectric Project
Great Lakes Hydro America, LLC

**VIA FERC Service**

**Reference: Response to Extension of Time and Additional Public Meeting Requests, and Request for Information for the Ripogenus Project No. 2572-133 and the Penobscot Mills Project No. 2458-247**

To the Parties Addressed:

On August 10, 2021, Commission staff issued Scoping Document 1 for relicensing the Ripogenus Project No. 2572-133 and the Penobscot Mills Project No. 2458-247. Staff conducted two public scoping meetings on September 9, 2021. Following the scoping meetings, several stakeholders filed letters requesting: (1) additional information from Great Lakes Hydro America (GLHA) and Commission staff; (2) an extension of time to file comments on the Preliminary Application Document (PAD) and study requests; and (3) an additional public scoping meeting. These stakeholders included the National Marine Fisheries Service (NMFS; September 13, 2021); the U.S. Fish and Wildlife Service (FWS; September 14, 2021); the Penobscot Indian Nation (PIN) and the Maine Council of Trout Unlimited (Maine Council TU), both on September 16, 2021; and the Maine Department of Marine Resources (Maine DMR) and Maine Department of Inland Fisheries and Wildlife (Maine DIFW), both on September 17, 2021. GLHA responded to the comments and requests on September 17 and September 24, 2021.

Request for Study Reports

NMFS, FWS, the PIN, Maine Council TU,[1] Maine DMR, and Maine DIFW request that GLHA provide copies of the reports from the studies conducted to support

[1] Maine Council TU requests that the 1996 Final Environmental Impact Statement for the projects (FERC, 1996) be provided to all stakeholders. The document is available on the Commission's eLibrary site at https://elibrary.ferc.gov/eLibrary/filedownload?fileid=000B4544-66E2-5005-8110-C31FAFC91712.

the prior relicensing proceedings and other references cited in the PAD.[2] The stakeholders contend that "while broad summaries of the studies performed during the last relicensing were provided in the PAD, a refined synthesis of the data was not provided, nor did GLHA identify data gaps." The June 11, 2021, PAD filed by GLHA meets the Commission's regulatory requirements at section 5.6(d)(3)(i)(B). GLHA made a good faith effort to comply with the regulations in sections 5.2(a) and 5.6(c)(2) by making the documents available at its offices in Lewiston and Millinocket, Maine. However, given advances in technology and the on-going concerns regarding the COVID-19 pandemic, it is reasonable for stakeholders to request on-line access to the studies used to develop the PAD. On September 24, 2021, as directed by the Commission's regulations at section 5.6(c)(2), GLHA filed the study reports requested by the stakeholders for the Ripogenus and Penobscot Mills Projects.

The PIN requests that the Commission provide to the stakeholders any and all information regarding the Commission's response to the *American Rivers* court case where the D.C. Circuit Court (D.C. Circuit) vacated Alabama Power's project license and remanded this matter back to the Commission for further consideration.[3] On June 17, 2021, Commission staff issued a draft supplemental environmental impact statement (EIS) for the Coosa River Hydroelectric Project No. 2146-111 that addresses the issues raised by the D.C. Circuit, which, along with other public documents in the proceeding, is available on eLibrary.[4] However, because this is an on-going proceeding at the Commission, the merits of the case cannot be discussed off the record.[5]

Extension of Time Request

NMFS, FWS, the PIN, Maine Council TU, Maine DMR, and Maine DIFW request that the Commission grant a 90-day extension of time, from when the information described above is received, to file comments on the PAD and study requests for the Ripogenus and Penobscot Mills Projects. The stakeholders state that without the original

[2] The stakeholders also request that GLHA provide 10 years of operations data for each project. This is a request for additional information and not a summary of information used to develop the PAD, and, therefore, is not addressed herein.

[3] *American Rivers v. FERC*, 895 F.3d 32 (D.C. Cir. 2018).

[4] Project No. 2146-111's draft supplemental EIS is available on eLibrary under accession no.: 20210617-3016, available here: https://elibrary.ferc.gov/eLibrary/filelist?accession_number=20210617-3016.

[5] *See* 18 C.F.R. 385.2201 (2020).

study reports, they cannot identify existing data gaps to inform appropriate study requests.

GLHA filed the PAD on June 11, 2021, and there are 120 days for stakeholders to review the PAD and file comments and study requests. There has been ample opportunity for stakeholders' review of the PAD and to request the study reports and other cited references. To delay the process now would push the Commission's Study Plan Determination to July 2022, which would delay the majority of the first year of studies to 2023, and delay any studies needed in the second study season to 2024. The results of any studies conducted in 2024 may not be completed in time to be included in the Preliminary Licensing Proposal (or Draft License Application) or Final License Application. Because the established milestones are designed to prevent undue delay in the relicensing process, and the timing of the field seasons would be negatively affected by a 90-day delay in the process, the stakeholders' request for a 90-day extension of time to file comments on the PAD and study requests is denied.

Request for Additional Public Scoping Meeting

NMFS, the PIN, and Maine DMR request that Commission staff hold an additional public scoping meeting. NMFS, the PIN, and Maine DMR state that the format for the evening public scoping meeting held on September 9, 2021, did not allow meeting participants to hear questions and comments during the meeting, which is contrary to the purposes of the public meeting. The PIN contends that this is a major deviation from the public scoping process and may have discouraged public participation in the meeting.

As was explained in the Commission's August 10, 2021 Public Notice and in Commission staff's SD1, due to on-going concerns with large gatherings related to COVID-19, we did not hold in-person public scoping meetings. Rather, we held virtual public scoping meetings that were recorded by Court Reporters. The transcripts of the meetings will be part of the Commission's record in the proceeding and will be available on eLibrary. Because stakeholders will have an opportunity to review the transcripts and provide comments in response to what was said at the virtual meetings, NMFS's, the PIN's, and Maine DMR's request to hold an additional public scoping meeting is denied.

If you have any questions regarding these matters, please contact Allan Creamer at (202) 502-8365, or allan.creamer@ferc.gov.

James Lepage, Bennington, VT.
I, James Lepage, am a property owner and taxpayer in the state of Maine at two properties. I own land on Caribou Lake, T3 R12, upstream of Ripogenus Dam. I have been at this camp for 41 years. I became aware of the relicensing of the dam, now in progress, and would like to see much more attention given to upstream water levels. Caribou Lake, Chesuncook Lake and the entire watershed upstream of Rip Dam has suffered from low water levels for well over 10 years. Some of this might be attributable to climate change, and therefore future controls on upstream levels will need to be changed for the benefit of wildlife, fish, and landowners. The lake level today is the lowest I have ever seen in 41 years, it is 170’ feet from the highwater mark to the lake at the deepest contour area of the lake system, and in more shallow areas over 500’ of exposed shoreline now take the place of shorefront camps or homes. I would like to see impact studies done on the these water level fluctuations, and the damage done to invertebrates, fish spawning/rearing/growth rates, property values, and wildlife. I hope you will consider my personal concern and requests before relicensing of Rip Dam is finalized. We must see some changes to current practices and aim higher to maintain better quality water levels above and upstream of the dam.
Sincerely,
Jim Lepage

Bennington, VT 05201

Supplemental comments to public comments on September 9,2021 by Charles Paone in Docket P-2572

I am attaching my original oral comments made on September 9th 2021 (Attachment 1) as no posting has yet been made on the FERC website . Since public comments were made on September 9th, GLHA filed data used to support its filing of 1991 for relicensing of Ripogenous dam. At that time, no additional data was filed to provide support for GLHA's current filing of 2021.

GLHA states that the Ripogenous impoundment is held relatively stable at 941.6 ft during summer months. Over the many years I have been on Caribou lake I have experienced significant fluctuations in lake level during the summer months. Since GLHA continually references overall impacts for the impoundment without specifying specific impacts on the individual basins that make up that impoundment, I am including some pictures to show you what the specific impacts are on Caribou lake.

Attachment 2 shows a picture of Caribou lake in September of this year with 170 ft of lake bed exposed. Although we are currently in a drought I have additional pictures which will show the fluctuation of the water levels in the summertime when GLHA claims the elevation remains relatively close to normal. I have additional pictures which will show the water lapping at the shoreline on July, 2017 while each of the previous two years the water during the same month of July is substantially away from the shoreline. The water levels in 2020 were similar to those experienced in 2021. I do not know what the elevation of the lake was during these years as GLHA has not provided that data but I can only assume it was well below the 941.6 ft.

The Ripogenous impoundment consists of six basins each with their own characteristics. No data has been provided to show the impacts of GLHA's water management on Caribou lake regarding drawdown effects on lake bed exposure, navigation and, recreational use other than the public statement by GLHA on September 9th admitting problems with access to the boat ramp on Caribou lake due to water levels.

The greatest concern is GLHA provides no commitment to monitor and collect annual data to evaluate the validity of the critical assumptions used to develop their water management plan. For example, one critical assumption is the spring inflows from the spring runoff. Without sufficient runoff we will see the lake conditions I have shown on attachment 2. Climate change makes this critical assumption and unknown going forward. Without sufficient inflow to the impoundment all the parties will be negatively impacted and may require periodic adjustments to the water Management plan **during** the next license period.

I respectfully asked the commission to require GLHA to conduct annual measurements to include impoundment elevations at late spring, late summer and, late winter. Also to consider the impacts on Caribou lake in its water management plan.

Clearly these are challenging times regarding the changing climate conditions. It would be reckless to develop a water management plan that does not provide for the collection of data on an annual going forward basis to both assess the validity of GLHA's assumptions and to provide the basis to make more accurate assumptions and to adjust the water Management plan as required to best meet the needs of all the parties.

Attachment 1

Comments on Docket P-2572 by Charles Paone (cpaonejr@gmail.com)

A review of this filing raises concerns regarding the impact the annual drawdown of the Ripogenus impoundment has on the water levels of Caribou lake. By early to mid summer Caribou lake often experiences a significant reduction in water level, even beyond the last two drought years. This reduction in the water levels and exposure of the lakebed makes it very difficult for access to the lake from the many houses located on it. Further with such low levels of water, navigation has become very hazardous and access to Chesuncook & Ripogenous lakes from Caribou lake is almost impossible and likely to be impossible by September. The Caribou boat launch is frequently made useless due to the low water levels in the summer.

The Pre-Application Document (PAD) states that the full pond elevation during normal times is 941.6 ft. It further states, "During normal operation and normal inflow years, the Ripogenous impoundment elevation is held relatively stable at 941.6 feet during summer months and is gradually drawn down starting in the fall, with a target low elevation of 913.6 feet by late winter, in anticipation of spring thaw and high flows." I have been on Caribou lake since 1968 and have frequently seen significant reductions of water and increases in lakebed exposure during summer months often in excess of 50 to 60 feet.

In paragraph 3.1.4 Proposed Environmental Measures, Great Lakes Hydro America (GLHA) proposes to continue to operate and maintain certain environmental measures. These measures include certain recreational resources such as, white water boating flows, operate and maintain 11 recreational sites and, a commitment to continue to collect recreation use information every 6 years. However, none of these measures addresses adequate water levels at Caribou lake and the impact it has on the recreational use of the landowners and homeowners on Caribou lake all of whom have made a significant financial commitment to the area.

Since this license would establish the criteria for operation for the next 50 years and given the obvious rapidly changing climate conditions that have been documented and well-established by many governmental agencies including NOAA, there needs to be a periodic review process to ensure that the critical assumptions used in developing the water usage criteria reflect todays environment and are adjusted in the future as necessary to reflect changing environmental conditions. Assumptions such as normal water elevation in the impoundment and normal inflows need to be continually monitored in order to determine what the appropriate outflow requirements should be. Certainly, it is unrealistic to assume the water level requirements that were established some time ago will continue to be appropriate in the next 50 years given the serious climate changes we are all experiencing.

It would be helpful to better understand these issues if the following information could be provided.

1. In what year was the normal full pond elevation of Ripogenous impoundment of 941.6 ft established?

2. In paragraph 3.1.3 it is stated that the Ripogenous impoundment elevation is held relatively stable at 941.6 feet during the summer months and is gradually drawn down starting in the fall.

A review of any studies or data for the last 10 years for the Ripogenous impoundment showing:

- the **actual** normal elevation at the start of summer per year

- the **actual** elevation starting at the beginning of fall per year.

- the actual maximum drawdown per year.

- the actual low elevation by late winter per year

3. Is there any data regarding water levels, recreational impacts, or navigation issues for Caribou lake?

Attachment 2

Brookfield
Renewable

September 30, 2021

***Via Electronic Filing***

Kimberly D. Bose, Secretary
Federal Energy Regulatory Commission
888 First Street, NE
Washington, DC 20426

**Subject:** **Ripogenus Hydroelectric Project (FERC No. 2572-133)**
**Penobscot Mills Hydroelectric Project (FERC No. 2458-247)**
**Supplemental Information – Virtual Site Review Information and Responses to Stakeholder Questions**

Dear Secretary Bose:

Great Lakes Hydro America, LLC (GLHA), a subsidiary of Brookfield Renewable and Licensee of the Ripogenus Hydroelectric Project and Penobscot Mills Hydroelectric Project (collectively referred to as the "Projects"), herein files supplemental information consisting of a copy of the PowerPoint slides presented by GLHA during the site review meeting as well as information in response to stakeholder questions and comments during the September 9, 2021 scoping and site review meetings.

On June 11, 2021, GLHA filed the Notices of Intent and Pre-Application Document (PAD), which initiated the formal relicensing proceeding to obtain two separate new licenses for the continued operation of the Projects through the Federal Energy Regulatory Commission's ("FERC" or "Commission") Integrated Licensing Process (ILP). Based on the ILP regulations and the Process Plan and Schedule provided in the PAD, FERC issued Scoping Document 1 on August 10, 2021, and subsequently conducted daytime and evening virtual scoping meetings on September 9, 2021. Additionally, during the afternoon of September 9, 2021, GLHA hosted a virtual environmental site review, which provided stakeholders with a comprehensive overview of the Projects utilizing drone video, photographs, and PowerPoint slides. Open question-and-answer sessions were held during FERC's daytime scoping meeting, as well as following the Project presentation during the virtual site review. GLHA notes that during the two question-and-answer sessions, all participants were encouraged to provide comments and to ask any questions regarding the Projects, and neither session was concluded until meeting participants had no further comments or questions.

## Virtual Site Review Information

As noted above, during the September 9, 2021 virtual site review meeting, GLHA provided a Project overview, including a PowerPoint presentation related to the Projects' previous relicensing, the current license requirements, water management, and environmental resource areas such as recreation, water quality, fisheries, wetlands and wildlife. Based on stakeholder requests during the virtual site review meeting, GLHA is filing a copy of the PowerPoint slides presented on September 9.

## Information Requests

During the two open question-and-answer sessions, GLHA addressed stakeholders' questions and comments. However, there were a few questions or requests that could not be addressed during the September 9, 2021 meetings. Therefore, GLHA is herein providing information that is readily available to try to address the stakeholder questions and comments noted during the meetings.

### Site Review Images

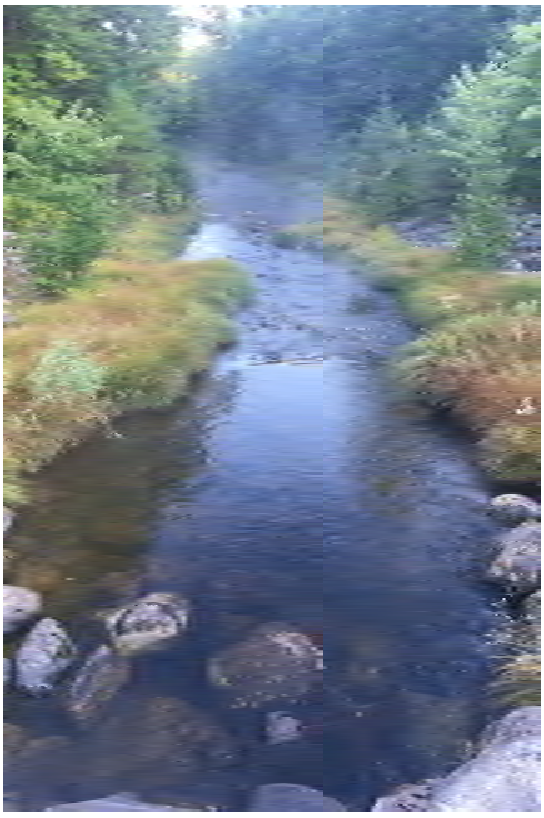
*Stakeholder Comment:* During the virtual site review meeting, stakeholders asked GLHA to indicate the dates on which the drone video and photographs presented during the Project overview were taken.

*GLHA Response:* GLHA collected drone footage on May 18-20, 2021, as further described below. Additionally, photographs of Project features were obtained on April 27-28 and May 18-20, 2021. The exceptions were the photographs included of Umbazooksus Stream East Campsite (the date of which is unknown) and Caribou Lake Boat Launch taken on September 27, 2018 (at an impoundment elevation of 925.6 feet).

| Drone Data Collection Date | Development | Location | Operating Conditions |
|---|---|---|---|
| May 18 | Ripogenus | Dam to McKay Station | Leakage flow from dam |
| May 18 | Ripogenus | McKay Station | Total flow of ~2,200 cfs |
| May 18 | Ripogenus | Holbrook Side Channel | Flow through both pipes into the channel |
| May 18 | Millinocket Lake | Pumping Station | No pumping (both pumps offline) |
| May 19 | Millinocket | Stone Dam | Leakage flow from dam |
| May 19 | Millinocket | Hydro Station | Total flow of ~2,050 cfs |
| May 19 | North Twin | Dam and Downstream | Total flow of ~2,100 cfs |
| May 19 | East Millinocket | Dam/Powerhouse | Total flow of ~2,200 cfs |
| May 19 | Dolby | Dam/Powerhouse | Total flow of ~2,200 cfs |
| May 19 | Millinocket Lake | Dam | ~75 cfs from dam into Millinocket Stream |
| May 20 | Millinocket | Back Channel | Leakage flow from Stone Dam |

### Holbrook Side Channel

*Stakeholder Comment:* During the evening scoping meeting, a stakeholder asked about the amount of flow entering the Holbrook Side Channel under minimum flow conditions in the West Branch.

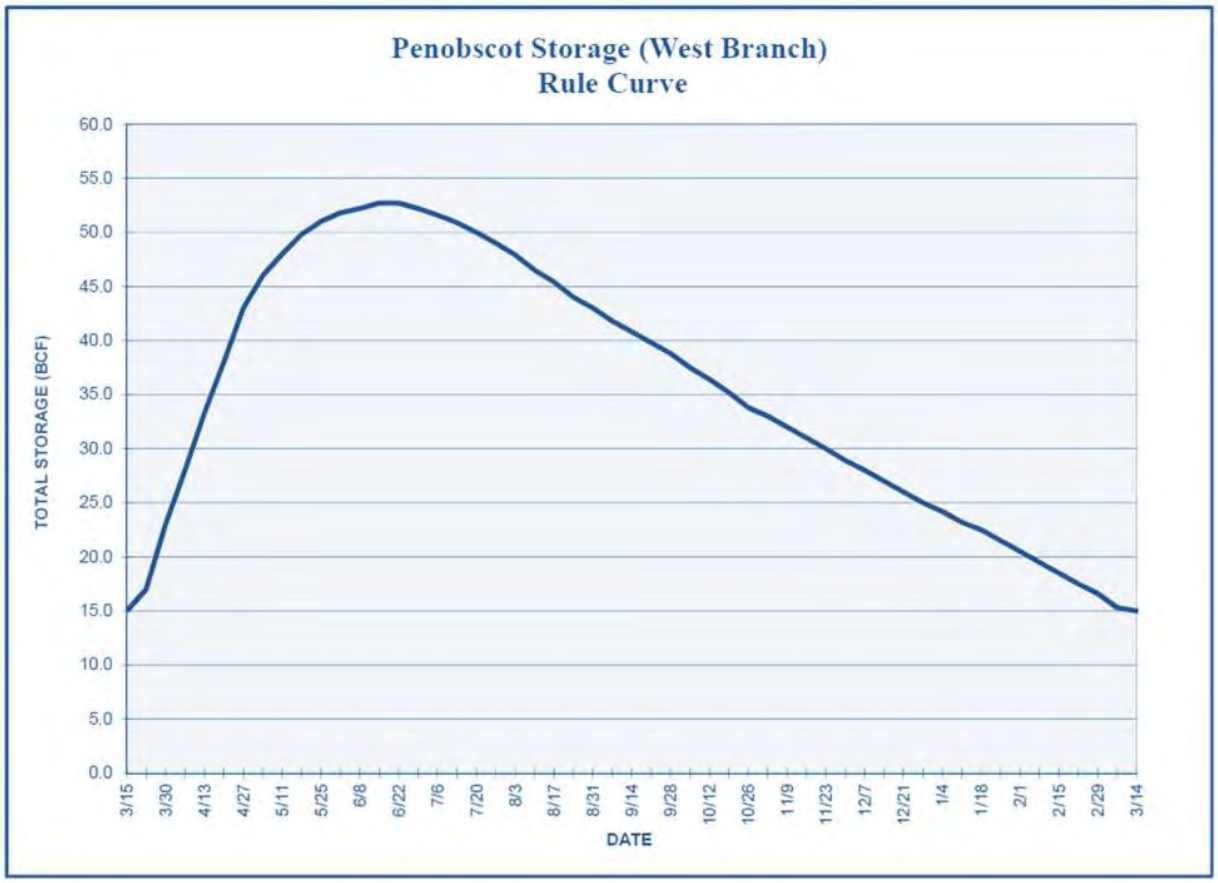


*GLHA Response:* As indicated in the PAD, the Holbrook Side Channel is a 1,400-foot-long channel located approximately 1.7 river miles downstream from the Ripogenus Dam in which flow is diverted from the West Branch for landlocked salmon spawning and rearing. Flow from the channel re-enters the West Branch approximately 1,000 feet downstream. Flows into the channel are controlled through two pipes, one of which is equipped with a valve that can be opened or closed to increase or reduce flow from the West Branch into the channel. Flows into the channel are designed to range between approximately 35 and 65 cfs during normal operating conditions, depending on the amount of flow in the West Branch.

Pursuant to license requirements, around June 1 each year GLHA closes the valve to reduce flow into the channel (for landlocked salmon fry emergence and production). Around October 15, GLHA opens the valve to increase flow into the channel (for landlocked salmon spawning).

GLHA periodically inspects the Holbrook Side Channel in support of annual maintenance; based on these inspections and the biannual valve adjustments, GLHA is not aware of the Holbrook Side Channel becoming dewatered. At times, debris may accumulate at the inlets to the discharge pipes resulting in a reduction of flow entering the channel; however, GLHA performs maintenance to clear the debris when observed.

Following the scoping meetings, on September 14, 2021 at 7:00 AM, GLHA staff obtained photographs (provided below) of the upstream portion of the Holbrook Side Channel where flow enters the side channel. The photographs were taken during the fry emergence and production period (i.e., low flow into the channel) when flows in the West Branch were approximately 1,000 cfs.



**Impoundment Rule Curve**

*Stakeholder Request:* During the virtual site review meeting, a stakeholder asked if GLHA could provide the rule curves used to operate the store-and-release impoundments associated with the Projects.

*GLHA Response:* As indicated during the virtual site review meeting, GLHA does not operate the Projects

using impoundment-specific rule curves, as the Projects are operated in conjunction with the upstream Storage Project (FERC No. 2634) as a storage system to meet overall system needs, including the flow and impoundment elevations required by the current licenses. Instead, GLHA uses a total storage-system guide curve indicating the available storage in the system in billion cubic feet (as provided below).

**Ripogenus Impoundment Elevations**

*Stakeholder Comment:* During the daytime scoping meeting, stakeholders asked if GLHA could provide photographs of the Ripogenus impoundment during lower impoundment elevations.

*GLHA Response:* As indicated in the PAD, the normal full pond elevation of the Ripogenus impoundment is 941.6 feet with a maximum drawdown of 44 feet (based on operational limitations of the Project). During normal operations and inflows, the Ripogenus impoundment is operated such that the impoundment is refilled following seasonal inflow after snow/ice-melt and is gradually drawn down throughout the year to meet overall system needs until a low elevation is reached in late winter to allow for the spring run-off and precipitation to refill the impoundment again. Below are photographs of Ripogenus impoundment taken in November 2001 when the impoundment elevation was approximately 919 feet (23 feet below full pond elevation). The year 2001 was the driest year out of the last 20 years.

**Photograph of Ripogenus dam from the Ripogenus impoundment when the impoundment elevation was approximately 919 feet (taken November 19, 2001).**

**Photograph of Ripogenus impoundment at the old Chesuncook Dam near the Chesuncook Dam Point Boat Launch when the impoundment elevation was approximately 919 feet (taken November 19, 2001)**.

**Effects on Impoundment Elevation during Millinocket Lake Pumping Station Operation**

*Stakeholder Comment:* During the virtual site review meeting, a stakeholder asked how impoundment elevations at North Twin and Millinocket Lake Storage Impoundments are affected during pumping operations.

*GLHA Response:* As indicated in the PAD, a pumping station is located on the west side of Millinocket Lake, approximately 6.2 miles from the dam, and it is used to pump water from Millinocket Lake into Ambajejus Lake within the North Twin impoundment. The pumping station consists of a concrete substructure and a brick superstructure with an adjoining intake section equipped with trashracks consisting of 3/16-inch bar steel with a clear spacing of 1 inch. Two vertical wet pit pumps each with a capacity of 250 Hp and 122 cfs (total capacity of 244 cfs), pump water to Ambajejus Lake via two underground, 4.5-foot-diameter pipes extending approximately 544 feet from the pumping station to the outlet structure. The outlet structure at Ambajejus Lake consists of a concrete substructure and concrete wingwalls. Two steel gates at the outlet structure can be used to prevent backflow from Ambajejus Lake when the pumps are not operating.

Assuming no other inflow, one pump, running for 24 hours, will result in a reduction of the Millinocket Lake Storage impoundment elevation of approximately 0.5 inch and an increase in the North Twin impoundment elevation of less than 0.25 inch. However, the actual effect to impoundment elevations is usually much less than described above, as there is typically tributary inflow into the Millinocket Lake Storage impoundment and tributary and controlled inflows (from the Ripogenus Project) into the North Twin impoundment.

GLHA primarily uses the pumps during periods of increased inflows to the Millinocket Lake Storage impoundment to: (1) stabilize the impoundment water level, and (2) attenuate high flow releases from Millinocket Lake Storage dam, which can otherwise contribute to flooding in the Town of Millinocket along Millinocket Stream. Any water pumped into the North Twin impoundment also benefits maintenance of the North Twin impoundment elevation and supplements hydroelectric generation at the North Twin and Millinocket powerhouses. GLHA avoids operating the pumps during the winter season to avoid thin ice conditions in the vicinity of the outlet at Ambajejus Lake, which can be a public safety hazard for snowmobilers.

**Shoreline Conditions at Low Impoundment Elevations**

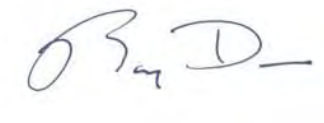
*Stakeholder Comment:* During the virtual site review meeting, a stakeholder asked about the amount of habitat that was dewatered when the impoundments were at their lower elevations.

*GLHA Response:* During the previous relicensing of the Projects, the effect of the seasonal drawdown cycles of the Ripogenus, Millinocket Lake Storage, and North Twin impoundments on aquatic habitat was thoroughly examined. The other Penobscot Mills Project impoundments were not evaluated as they are operated in a run-of-river mode and experience only minimal impoundment fluctuations.

In north temperate lakes the maximum primary productivity, aquatic community growth and

development, occurs predominantly during the ice-free "growing season." Therefore, impoundment drawdowns typical (median) of the growing season (May 1 through October 31) were examined and the amount of aquatic habitat dewatered during this period was estimated. At the Ripogenus impoundment, it was estimated that 2,064 acres of littoral habitat were dewatered between full pond elevation (941.59 feet) and the median growing season drawdown elevation of 936.92 feet. At the Millinocket Lake Storage impoundment, it was estimated that 493 acres of littoral habitat were dewatered between full pond elevation (480.0 feet) and the median growing season drawdown elevation of 478.82 feet. At the North Twin impoundment, it was estimated that 1,445 acres of littoral habitat were dewatered between full pond elevation (491.92 feet) and the median growing season drawdown elevation of 489.09 feet.

These results are described fully in Volume VIII of the License Applications filed in December 1991 for the Ripogenus and Penobscot Mills Projects, respectively.



**Recreation Facility Parking Spaces**

*Stakeholder Comment*: During the virtual site review meeting, a stakeholder asked how many parking spaces were available at each Project recreation facility.

*GLHA Response*: As indicated in the PAD, GLHA proposes to perform a Recreation Facility Inventory and Condition Assessment for each Project in support of obtaining new licenses for the Projects. As part of this assessment, GLHA will document the current number of parking spaces available at the Projects' recreation facilities with results provided in the Initial Study Report, which is anticipated to be filed with FERC during the second quarter of 2023.

If you have any questions regarding this information, please contact the undersigned at (207) 775-5605 or randy.dorman@brookfieldrenewable.com.

Sincerely,

Randall Dorman
Licensing Manager, Brookfield Renewable

Comments on the PAD and Commission staff's Scoping Document 1, Ripogenus Project (2572 – 133) and Penobscot Mills Project (2458-247)

My name is Edward Spear. Beginning in 1977 and continuing into the early 2000s I worked for (then) Great Northern Paper (GNP) as a fisheries biologist with my primary responsibility being the West Branch of the Penobscot River (WB) drainage (from the Quebec boundary to the Medway Dam). During this period, I collected and analyzed data and co-authored FERC applications for Big A, Ripogenus, Penobscot Mills, and the Storage Projects. During that time, I participated in numerous agencies, stakeholder, and Non Government Organizations workshops and meetings as well as overseeing mitigation and enhancement measures. I believe I qualify as an expert of the West Branch of the Penobscot River drainage. The following comments are a continuation of verbal testimony made on the evening of September 9, 2021 and should be regarded as expert testimony.

This winter Great lakes Hydro America GLHA a subsidiary of Brookfield Renewable (Collectively the Licensee) filed a Notice of Intent (NOI) and a Pre-Application Document (PAD) for the now combined Ripogenus and Penobscot Mills Projects. Flash forward 25 years. There are no longer paper mills connected to the hydro system and the interconnection to the grid has been upgraded. Economic signals from the market place put more value on peak power than base-load power. The Licensee has responded to those incentives by using the West Branch system as a massive spinning reserve power source to enrich its coffers at the expense of the balance heretofore beneficial to the fisheries of the system. It is my contention that this operation was not allowed under the existing operating licenses, and should be specifically prohibited going forward. While (hourly) archival flow data are not available, peaking flows appear to extend downriver to West Enfield (USGS flow records for West Enfield) on the mainstem Penobscot. For all facilities, the Licensee needs to make (1997- current) hourly river flow, power generation and impoundment elevation records available to the public.

To summarize, the PAD stated that nothing had changed “the licensee maintains that nothing has significantly changed” and fisheries and aquatic communities are healthy. They say this without any studies or presence on the WB in nearly 20 years! Section 1-11 of the notice states “the licensee maintains that a full suite of new studies is not needed, that the vast body of information on which today’s certifications and licenses are soundly based and should be relied upon for these relicensings”. Brookfield has sponsored a number of studies in the Magpie and Batchawana Rivers

(Marty et al, 2009, Smokorowski et al, 2010) and is well aware that for the Ripogenus and Penobscot Mills projects and the change to peaking operations, nothing could be further from the truth. Fish and macroinvertebrates are well below the 1980s levels used in the 1992 license application and the (final) Environmental Impact Statement (EIS) and 1996 license. Below North Twin Dam and Mill One Station salmon populations have also declined and with these declines, so has salmon angling activity and success.

Landlocked salmon (Salmo salar) are the primary sport fisheries inhabiting the West Branch drainage. The Maine Department of Inland Fisheries and Wildlife (MeDIFW) manages these river segments and impoundments of the West Branch for this species. The segment of the WB below Ripogenus Dam downstream to Debsconeag Falls supports a unique Landlocked salmon (salmon) fishery. All life cycles, spawning, nursey, summer, and overwintering habitat occur in the water below McKay Station. Salmon spent their entire life in the West Branch, rarely moving downstream. The EIS states "(West Branch, downstream of McKay Station) fishing quality is high at 0.41 fish per day. The average size is 18.2" and 2.2 pounds" (EIS 3-37). The existing fishery is now limited to the 1.25 miles below McKay Station (communications with WB anglers). An eighteen inch salmon is now a trophy (personal communications and observation) rather than the historic norm. The EIS states the West Branch below McKay Station is a unique fishery. The current fisheries (and aquatic communities) need to be returned to 1980's and 1990's levels and deserve full protection.

Flows below McKay are no longer "relatively stable" and salmon abundance and growth has suffered. Studies have shown that juvenile salmon are forced to relocate (Scruton et al., 2011) during peaking events resulting in loss of feeding time, energy expenditure and subject to predation. Studies of adult salmon whose life-history is totally contained in a riverine environment is limited to the West Branch below McKay Station and possibly Indian Pond/Harris Station (where successful riverine reproduction has NOT been identified). Thus, only the Indian Pond study on salmon and peaking is available. The Indian Pond Project (FERC 2142) studied movement of salmonid fish below Harris Dam. While downstream movement was generally absent, salmon moved laterally to avoid higher velocities during peaking events (EPRO 1999). Thus, most impacts of peaking operations are found in studies of other closely related salmonid species. Quinn and Kwak (2011) found brown trout (Salmon trutta) and rainbow trout (Orcorhychus mykiss) were found in velocity refugia near an Ozark river's margin during high flow. Ayllon et al (2008) found that age I+ and older brown moved in response the flow and velocity changes. Lagarrigue et al (2002) found reduced brown trout abundance below a hydro system when compared to a "control site" in in the French Pyrénées. While numerous studies suggest that peaking operations have little effect on up or downstream movement, lateral movement and habitat selection in response to flow alterations may seriously reduce salmon feeding activity and growth

Fisheries concerns of the 1996 license focused on maintaining the existing 1980s fisheries (virtually all WB data are from studies conducted in the 1980s) and increasing production of salmon parr (identified as the factor that limited the WB salmon population). A dewatered side channel below Holbrook Pool provided an opportunity to create habitat for the limiting salmon life stage(s), age 0+

and 1+ salmon (parr). Article 406 required providing flow to this previously dewater river section. This was provided by excavation and by placing two gated operated culverts that extended out into Holbrook Pool. Depending on season (spawning or "growing") flows of between 35 and 65 cfs would be passed though the gated system. Studies prove the plan a success. Changes in project operation from the traditional "mill operations" to peaking changed age 0+ and parr production. Juvenile salmon are vulnerable to peaking flows **(Scruton et al, 2011).** At flows of 1800 cfs flow into Holbrook are serious reduced and flows of 1000-1100 cfs dewater the side channel eliminating Article 406 goals and seriously jeopardize parr production in mainstem reaches. Low (1100 cfs) flow occurred during a weekend in late July and have routinely continued during early September. Any enhancement visualized by Article 406 was lost.

The West Branch downstream of McKay Station was once famous for mayfly (ephemeral) and caddis (Trichoptera) hatches, notable Hydrophycid that favor high velocity areas. Trotsky and Gerogory 1974, found peaking flows below Wyman Dam reduced aquatic insect abundance. Cushman (1985) in what is best described as literature review, compiled an excellent study of the alterations to fish and macroinvertebrates caused by peaking operations. Mayfly hatches that once clouded the sky in late May have declined to a point where few anglers fish the runs/pools immediately above Neswodnehunk Deadwater. Caddis hatches have declined to the point where they no longer fill outdoor lanterns after sunset. Lesser species such as morning and evening duns (baitids) are no longer common. All these species are critical food items for juvenile and (during the summer "maintenance period") adult salmon in their larval (naiad) and adult stages (sub imago, imago) or in the case of caddis, pupae and moths. In 1981, Normandeau Associates surveyed multiple locations of the WB below McKay Station. The results are shown in the Big A application and should be easy to duplicate.

Smelt (Osmerus mordax) are the critical element of growth and survival of adult salmon. West Branch salmon in the reaches below McKay Station as well as salmon below North Twin and Mill One tailwaters depend on smelt spawned in streams (and the upper West Branch) that empty into the many Ripogenus and North Twin impoundment shallow embayments. Larval smelt spawned during the end of April, drift into these embayments before moving into deeper water areas where they feed on zoo plankton in or just above the thermocline. This life stage strategy segregates the young-of-the year (YOY) from adult smelt (that are cannibalistic) that inhabit areas in or below the thermocline. As the YOY smelt move is search of food and space they wander into the McKay, North Twin and Mill One station intakes and provide the critical downstream food source for sub adult and adult salmon. These phenomena occur in most months, with mid to late April, as the impoundments fill, being the period of least drift. During the 1980's West Branch smelts catch was in the range of 25,000 pounds annually (SEE Big A application) and smelt could be seen washed up along the Big Eddy shore. Similar smelt catches were recorded below downstream facilities. Smelt are no longer seen in the lower stretch of the river and only once reported washed up at the Big Eddy in the last five years. Salmon growth and abundance has suffered. The lost/shifting of

Ripogenus impoundment littoral areas caused by draining the impoundment for peaking power is a likely reason for the reduced smelt production.

Lake white fish (LWF) that were once common in the Ripogenus impoundment declined in the 70's and numbers observed during the 1996 relicensing studies revealed only a small population near Umbazookas Stream. Laval LWF are extremely vulnerable to predation by smelt (Gorsky and Zydlewski 2013, Loftus and Hulsman, 1986). What was presumed to be a relic LWF population observed at the confluence of Umbazookas Stream, was assumed to be a pre-spawning concentration. LWF spawn in mid-November and fry drift into embayments after ice out. The timing of fry outmigration and post spawning activity is identical to smelt. Adult smelt are very predaceous and the timing of (post spawning) smelt-whitefish fry behavior has been the given for the reason of declining LWF stocks in the Great Lakes (D. H. Loftus and P. F. Hulsman, 1986), given the decline in the Ripogenus smelt population, a full pond operation from May 1st though July 15 would provide addition shallow littoral areas such as Umbazookus Bay for juvenile LWF escapement from (adult) smelt.

Water Use Plan: Until recently (circa 2005), West Branch flows were used to generate power for paper production and impoundment(s) storage was closely monitored to ensure that storage would not be depleted. Weekly flow and generation followed what was called a "rule curve". The Water Use Plan (WUP) was developed from and followed what was then "called rule curve operations". While the need for storage for paper making is gone, the need to provide (biological) flow in the months before spring runoff remains. The present license(s) require flows during the (salmon) spawning and incubation period except in "events beyond the applicant's control". There is no prohibition on running out of storage thus there is no guarantee that the West Branch below McKay Station won't revert to the pre-McKay era of winter flows in the 200 cfs range. Flows below North Twin dam are governed by state charter that requires 2000 cfs "by Millinocket". The WUP needs to be revisited to ensure Ripogenus impoundment storage is available to meet biological flow needs e.g., 1450 cfs, during winter and spring.

Upper Gorge flow; Article 401 of the Ripogenus License requires, in order to produce fishing opportunity, an Upper Gorge (UG) flow of 100 cfs beginning on July 1st. Historical flow into the UG was though a "deep gate" and provided a flow cooler than the surface discharge of the McKay Turbines. Presently, UG flow is through a small sluice gate (historically used for logging) and provides (warmer) surface water. In effect, this flow regime acts more as a fish repellent than attraction. This was not what was intended by the authors (namely MeDIFW) in the licensing proposal. The EIS took a simplistic view of the UG plan. While increased fishing opportunity was the primary goal, the (hoped for) cooler UG flows would provide a thermal refuge and "spread out" the salmon population during the warmer summer months thus reducing stress and predation.

Salmon fishing has declined at North Twin (Dam) and Mill One (formerly the Grinder Room) tailraces. These fisheries can easily supplement by providing flow into the backchannel (the historic West Branch channel). The EIS traded 200 backchannel (legal sized) salmon for 243 Mill jobs.

Neither the GNP Mills nor jobs exist today and the opportunity to replace lost fishing opportunity should be investigated. In the event that downstream escapement form the North Twin Impoundment proves inadequate, salmon could be easily stocked. Somewhat overlooked in the EIS is the fact that Shad Pond would provide excellent (salmon) over-wintering habitat.

For the reasons outlined above, FERC should require extensive studies that will provide information needed to restore the WB drainage to 1980s fish and aquatic community levels discussed in the 1996 EIS. The licensee's PAD filing suggests a total lack of knowledge of present WB drainage wide fisheries and aquatic conditions. FERC has a duty to mandate the necessary studies. All fisheries related studies should be supervised by MeDIFW as it is the (state) agency that has (fisheries) responsibility.

Thank you for the opportunity to respond

Jeffrey Scott Murphy, Orono, ME.
Email from Jeff Murphy (NMFS) to Randy Dorman (GLHA) and Jim Gibson (HDR) dated October 1, 2021

Hello Jim and Randy - Thank you for providing estimates of the amount of riparian habitat exposed in the Ripogenus, Millinocket Lake, and North Twin impoundments in your September 30, 2021 letter to FERC. However, I believe the question raised during the Sept. 9, 2021 virtual scoping meeting was related the the amount of littoral habitat that is exposed in the project impoundments during their lowest licensed elevations rather than during the "growing season". Based upon data presented in the June 2021 PAD, I understand that:

1)The current license for the Ripogenus Project allows for a drawdown up to 44' feet ( El. 897.59'); your September 30, 2021 letter filed with FERC provided estimates for exposed littoral habitat at a 4.67 foot drawdown.
2)The current license for the Penobscot Mills Project allows for a drawdown up to 22 feet ( El.469.92') at the North Twin Impoundment; your September 30, 2021 letter filed with FERC provided estimates for exposed littoral habitat at a 2.83 foot drawdown.
3) The current license for the Penobscot Mills Project allows for a drawdown up to 6.2 feet ( El.473.8') at the Millinocket Lake Impoundment; your September 30, 2021 letter filed with FERC provided estimates for exposed littoral habitat at a 1.18 foot drawdown.

Clearly, vastly greater amounts of littoral habitat are exposed at each project impoundment at their lowest licensed elevations. I could not locate any estimates of littoral habitat exposed at the lowest licensed impoundment levels in VIII of the License Applications filed in December 1991 for the Ripogenus and Penobscot Mills Projects. If this information does not presently exist, it will be necessary to develop it for this relicensing.

Thank you, Jeff Murphy.

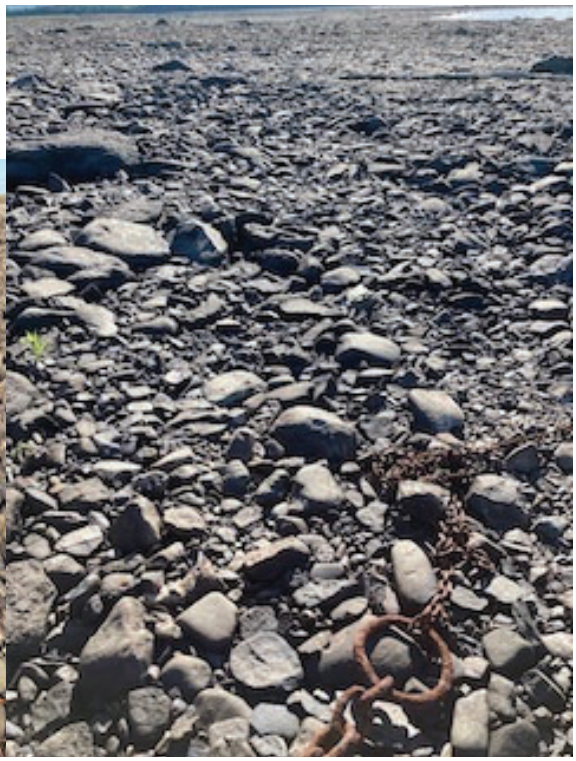
RE: Comments on the PAD/Site Review for Ripogenus Hydroelectric Project (FERC No. 2572-133) from Kathleen K. Houston

Dear Secretary Bose:

After attending both Scoping Sessions and the Site Plan Review, I am writing to address concerns about misinformation presented and address inconsistencies from the previous licensing process. My concerns are as follows:

**Claims of stable water levels are simply not true. This instability greatly negatively impacts camp owners, recreationalists, and the ecological integrity of the area**

The PAD claims (pg 442),



"*During normal operations and normal inflow years, the Ripogenus impoundment elevation is held relatively stable during the summer months and is gradually drawn down starting in the fall with a target low elevation by late winter in anticipation for the spring thaw and freshet."*

Lake levels have not been stable since at least 2003 and drawdown often begins in early summer.

As a camp owner unstable water levels have impacted my family significantly. It has rendered our dock and moorings unusable. We must now use three different moorings, each two hundred feet apart to be able to moor our boat from June - August. Our third mooring is over 600 feet from the high-water level mark and is currently unusable. Water levels fluctuate vastly during the summer months. It is extremely difficult to walk over this terrain, posing safely risks.

The images below illustrate some of the difficulties:

*Our first mooring August 2021 The second mooring high and dry*

A simple hand pump with a small hose easily pumped water from the nearby lake. Now, unstable lake levels render the pump unusable, and we needed to purchase a gas water pump and hundreds of feet of hose to get water from the lake, as the image below illustrates. *Water pump from lake to camp.. For scale, the white dot in front of camp is a person! August 2021*

**The public recreation experience is diminished**.

In the 1996 EIS, the Department of Conservation recognized …

*"the high quality resources….make the Ripogenus Project area one of the most important recreation areas in the state."*

This statement is still true today. Water fluctuations negatively impact the recreational lake user. Public campsites, required by the Applicants license, are hundreds of feet from the water, diminishing the aesthetics of the experience and increasing the difficulty of a trip. As a licensed Maine Recreational guide for over 30 years, I know how difficult it can be for visitors to the north woods to have to lug equipment and personal equipment over uneven, lengthy distances. Sites so far from the water are also a safety concern. It is very difficult to carry water for putting out fires over long distances and unstable terrain. Despite the hard work and efforts of the Department of Conservation staff, some sites are very difficult to use and access.

*The view from the lake to a public campsite. September 2021*

**The aesthetic experience of recreationists is diminished.**

The recreational importance of the Ripogenus project can't be overstated. The local economy depends on the boating, swimming, canoeing, and recreating public – a public that expects a visually pleasing surrounding. As the Environmental Statement (EIS) submitted in 1996 identifies,

"*Visual elements of the project area contribute to the quality of the recreational experience. Exposed rocky shorelines and stream beds can detract from the overall visual experience, particularly when associated with recreational use of the area."*

The images below document the current visual experience. Despite the beauty of Katahdin, the experience is diminished. Visitors to the lake have referred to the shoreline as a "moonscape."

*Is this the aesthetic quality we strive for in one of Maine's "gem" lakes? Sep 2021*

**Lack of Public Access Between Lakes.**

The Applicant's permit requires *"provisions to maintain appropriate public access."* Due to navigational hazards exposed by fluctuating water, access between lakes is nearly impossible as the images below confirm. This diminishes the angler's opportunities as well as the recreationists experience. *Caribou and Chesuncook Lakes Thoroughfare - 2020*

**Significant biological changes** are also taking place. At the Site Plan Review representatives implied the current water levels are an anomaly. Yes, there is a drought. However, my family remembers when all exposed littoral zone was rocky. Now, as the image below illustrates, hundreds of feet of shoreline are covered in plants and trees. This level of succession is not the result of a one, or even two-year drought. It is the biproduct of years of fluctuating water levels.

*September 2021*

**<u>Representation of boat landings at the Site Plan review, and in the PAD is vastly different than reality</u>**

The PAD (page 338) provides images of Chesuncook Boat landing and claims the site includes,

*"an improved gravel boat launch…..provides year-round access to Ripogenus impoundment for various recreation activities including boating, fishing, snowmobiling, and more,"*

as required by the project's license. The images below confirm the boat launch is not improved gravel, but instead a long, irregular, scree-like landscape that is difficult to navigate and treacherous on automobile tires. The shallow water makes it difficult, and sometimes impossible

to launch boats. You can see the images below are drastically different than those presented in the PAD. In addition, the boat landing has received no maintenance in over 10 years.

*The Chesuncook boat landing – August 2021.* *A close-up of the boat landing terrain*

**Claims of alternative boat landings and lake access are untrue.**

At the Site Plan Review representatives claimed the public could use a nearby private boat launch if the boat launch GLHA is obligated to provide becomes unusable. That is grossly inaccurate. The nearby private boat launch became unusable in August of this year and charges a fee.

In the 1996 Environmental Impact study, submitted by the applicant at that time, Commissioners were told,

*"Current operations of the Ripogenus impoundment results in annual water level fluctuations of as much as 44 feet. Since 1972, the maximum draw-down during the summer recreation period (between Memorial Day and Labor Day) has been 15.25 feet****: the average has been 3.5 feet (3.10.4.1).***

As the Impoundment Level chart below indicates, water levels did not fluctuate then as they currently do. The impact of facility operation can only be analyzed and mitigated with current, accurate data. Using thirty-year old data and studies to make a decision that will impact an entire region for the next 30 years is irresponsible and inadequate.

Figure E2-3 Ripogenus impoundment mean weekly water surface elevations for the period 1972-1985. Maximum and minimum daily recorded elevations during this period of record are noted on the figure.

Balance is essential to this large and complicated project, encompassing a variety of stake holders, for judicious use of the resource. Previous management of the facilities were able to meet this balance, providing for both downstream water needs including whitewater, waste management, and fisheries without significantly negatively impacting Chesuncook, Caribou or Ripogenus lakes. This is no longer the case, despite the rosy picture painted by GLHA. To fully understand the facilities impact on the lakes, the commission needs to have current, accurate, honest data to analyze.

**I respectfully request FERC require the Applicant provide stakeholders with ten years of operations data for the Ripogenus Project including impoundment elevation and daily outflows. This easily obtained data is necessary to gain an accurate understanding of the water bodies, and for fisheries and wildlife experts to identify neeeds. The public has a right to this information, and it is critical to any decision making.**

Previous decisions about the Ripogenus project were based on very different lake realities than experienced today, including the following statements and data:

1. quotes referenced above from the Environmental Impact study. *"Current operations of the Ripogenus impoundment results in annual water level fluctuations of as much as 44 feet. Since 1972, the maximum draw-down during the summer recreation period (between Memorial Day and Labor Day) has been 15.25 feet****: the average has been 3.5 feet (3.10.4.1)***

2. statements made about the WUP, *"the resulting Water Use Plan was included in the FERC relicensing and 401 certification…..The plan proposes no significant changes from the historic lake level management of Ripogenus Impoundment (1991)*
3. meetings between GNN and MDP in June of 1991 where:
    A. *"the MDEP expressed the position that the historic water management practices in the Ripogenus Impoundment may not be protective of littoral zone biota."* The concern must be much greater now.
    B. GNN *"proposes to continue drawdowns from the Ripogenus Impoundment seasonally as they have historically between normal high water elevation of 941.59 ft. and* ***an average drawdown of 20 ft****."* (pg 3 of meeting notes).
4. Charts of impoundment elevations from the time

The above data, combined with other information, influenced previous licensing decisions, and led to the current UAA. The current reality is vastly different. However, only personal anecdotal data exists as GLHA has not been willing to provide lake levels as the previous owner did.

**In addition to ten years of operations data including impoundment elevation, I strongly support the study requests submitted by the US Fish and Wildlife as they are the experts and need the studies to ensure the protection of water quality, fish and aquatic resources, endangered wildlife, and wetland, riparian and littoral vegetation.**

The Federal Power Act reminds us of the purpose of licensing in these words:

*"the Commission…give equal consideration to the power development purposes and the purposes of energy conservation, the protection, mitigation of damage to, and enhancement of fish and wildlife, the protection of recreational opportunities and the preservation of other aspects of environmental quality.." (section 4(e)10(a)).*

As this letter describes and documents photographically, damage has already been done. Additionally, fluctuating lake levels raise the potential for ongoing and future harm to fish, wildlife, and lake ecosystems, as well as negative economic impacts on this treasured recreational area.

There are few treasures that remain for everyone. Chesuncook, Caribou and Ripogenus lakes are just that. Steeped in tradition, home to generations of Mainers, and those from away, these gems must be protected. I urge you to consider the impact of your decisions, not just on its benefits to the hydroelectric project, but also on the long-term consequences to the lake, the rivers, the land, and our communities.

Respectfully,

Kathleen K Houston

TROUT UNLIMITED
MAINE COUNCIL

**Via online submission to: http://www/ferc.gov (cross-filed)**

Subject: **Second Preliminary Comments of Maine Council of Trout Unlimited on the Notices of Intent and Pre-application Documents for the Ripogenus Project (P-2572) and the Penobscot Mills Project (P-2458)**

Dear Secretary Bose:

On behalf of its six chapters and over 2,000 members, Maine Council of Trout Unlimited (TU) submits these comments related to the Notices of Intent (NOI) and Pre-application Documents (PAD) for the Ripogenus Project (P-2572) and the Penobscot Mills Project (P-2458) filed for Great Lakes Hydro America, LLC by Brookfield Renewable ("Brookfield") dated June 11, 2021,[1] TU's subsequent request for access to documents referenced in the PAD and a 90-day extension to review them,[2] the Brookfield responses and subsequent provision of a portion of the requested documents,[3] and the Commission's denial of the request for an extension.[4]

TU's request for referenced documents and a 90-day delay was in support of the initial request by NOAA Fisheries.[5] Information requests and a 90-day delay were submitted by the U. S. Fish and Wildlife Service (USFWS),[6] the Penobscot Indian Nation (PIN),[7] Maine Department of Marine Resources (MDMR),[8] and Maine Department of Inland Fisheries and Wildlife (MDIFW).[9]

[7] Penobscot Indian Nation RE: Extension of Time Request, Data Request, Legal information request and repeat of the Public Scoping meeting request for the Ripogenus (FERC No. 2572-133) and Penobscot Mills (2458-247) Hydroelectric Projects letter dated September 13, 2021.
[8] Maine Department of Marine Resources letter RE: Extension of Time Request for the Ripogenus (FERC No. 2572-133) and Penobscot Mills (2458-247) Hydroelectric Projects of September 17, 2021.
[9] MDIFW letter RE: Extension of Time Request for the Ripogenus Hydroelectric Project (FERC No. 2572) and Penobscot Mills Hydroelectric Project (FERC No. 2458) dated September 17, 2021.

Brookfield's response described these requests as "*beyond the intent of 18 CFR §5.6(c)(2)*" yet Brookfield did subsequently provide the last license applications and supporting documents and a Use Attainability Analysis (UAA) for Chesuncook Lake. The TU request for documents was specific and is quoted below. Requests that were met by the documents that Brookfield supplied are indicated by strikethrough.

1. *(MDIFW 2012) - page 5-92*
2. *(FERC 1996) - page 5-92*
3. ~~*(GNNC 1991b) - page 5-93*~~

15. ~~*(Nedeau et al. 2000) - page 5-133*~~
16. ~~*(Swartz and Nedeau 2007) - page 5-133*~~
17. ~~*(Swartz 2007) - page 5-143*~~
18. ~~(Dewan & Assoc., 1990b) - page 5-247~~

Please note that the documents that remain were produced subsequent to the last license applications and could not be part of the supplied documents. Of additional note is that item 10 is unpublished. These references do not appear in Brookfield's follow-on letter of September 24[10] that provided locations for referenced information. Footnote 1 on page 1[11] states: "*[1] Maine Council TU requests that the 1996 Final Environmental Impact Statement for the projects (FERC, 1996) be provided to all stakeholders. The document is available on the Commission's eLibrary site at https://elibrary.ferc.gov/eLibrary/filedownload?fileid=000B4544-66E2-5005-8110-C31FAFC91712* "

TU did not make this request, TU requested the specific documents listed above. The link the footnote provides is to the documents that Brookfield had already supplied.

The Commission's finding that the applicant was not required to provide the studies requested by agencies, PIN and TU will complicate agency efforts to identify data gaps. The task they face is daunting. Summary reports do not allow expert evaluation: they do not provide information on exactly where data was collected, methodology used, parameter ranges, assumptions, etc. As TU has previously stated, things were very different thirty years ago during the last relicensing when the electricity went directly

[10] Brookfield letter Subject: Ripogenus Hydroelectric Project (FERC No. 2572-133) Penobscot Mills Hydroelectric Project (FERC No. 2458-247) Supplemental Information – Source Information and Existing Studies dated September 24, 2021

[11] FERC letter Reference: Response to Extension of Time and Additional Public Meeting Requests, and Request for Information for the Ripogenus Project No. 2572-133 and the Penobscot Mills Project No. 2458-247 dated September 28, 2021.

to the mills in Millinocket. The power requirements were different, and many stakeholder comments have stated that the projects are now operated differently. Continuing low water levels on Ripogenus - Chesuncook Lake are striking. Climate change is likely an important additive factor to the apparent changes in project operations. Without detailed study information, the applicability of past studies is questionable at best.

**Trout Unlimited reiterates its support for the agency requests for refined data and asks that the Commission require that the applicant provide the information requested in electronic form *in advance of* the Proposed Study Plan Meeting along with the specific referenced studies that we requested, *so that we may understand the existing information before we must draft study requests*. TU additionally requests that FERC criteria for additional studies be applied more permissively than is generally the case to any requests that the agencies, PIN or NGO may submit later in the process when important information is still lacking.**

Maine TU Council appreciates the opportunity to provide these additional preliminary comments on these important projects and hopes that the Commission will act to allow the resource protection agencies to identify potential harms to the resource and thus enable the Commission to balance project harms and benefits.

Respectfully,

Stephen G. Heinz
Maine TU Council FERC Coordinator

Owen Genest, Sanford, ME.
My name is Owen Genest. I have been coming to the Chesuncook Lake region since the early 1990s. My grandfather has had a few camps off of Chesuncook Lake Rd, near the Boom House and forest ranger station. His current camp has the largest piece of waterfront land other than the Allagash Gateway Campground on the land leased by the Cushing family. Unfortunately for him and the rest of the family, the term waterfront isn't as accurate as it once was. Only for a very short window of time over the last few years could the lake be considered full. Usually its for the month of May into early June. This year however, the lake never got above somewhere around 8-10' below the normal high water mark, depending on the elevation that is considered. I understand the nature of the drought that the northern portion of Maine has gone through in the last couple years as well as the lack of snow pack above the lake. What I can't seem to understand is with those things considered, why does the Penobscot River below Ripogenus Dam stay well below standard water elevations. It would seem that if Chesuncook Lake was in such a significant state of drought that the lake is 20-25 ft lower than high water elevation, the river should follow suit and be flowing at a significantly lower flow velocity therefore having a much lower water level.

The water level has been concerning for a few years now during the fall, but it has been back up the following spring. This year was the worst yet. Normally a standard safe boating season on Chesuncook for someone that isn't very familiar with the lake goes from Memorial Day to July 4th. It can go longer, if one is prepared and familiar with the lake, but the nature of the lake is that there are many subsurface obstacles and hazards that are completely unmarked and invisible. 2021's boating season effectively never started. The water level at Memorial Day was approximately the same as the year prior's mid July. There is also no way to keep a functional dock or even mooring with the amount of fluctuation of the water levels of the lake.

This year's water level has made launching a boat a dangerous task, as the boat launch at the Boom House is passable when the water is high, but it is filled with jagged rocks that decimate even the most rugged tires. the average person not accustomed to the ways of the regions roads would not be able to recreate on the lake with an average vehicle as the launch is just too hazardous.

My grandfather has had him camp for sale for the last few years as he is getting older and he isn't using it as much anymore. I have given tours to many potential buyers over these years, and the biggest thing that has scared them away is the insane lake level fluctuations. One couple I talked to this spring loved the lake and the area as well as the camp, but couldn't wrap their heads around the idea that sometimes the lake is just 20' low and effectively impassible via boat. The lake level fluctuations have actively hurt his ability to sell the camp to the point that he has just decided to keep it in the family as he can't see it go for less than it's worth due to the water levels.

My education is in Civil and Environmental Engineering with a previous path in Biology. I am genuinely concerned about the ecological and biological ramifications

of the lake fluctuation and especially as low s the water is this year.  Last year, I drove around the north end of the lake, where Umbazooksus Stream comes into the lake and it was dry.  I'm not sure of the spawning habits of the native fish in Umbazooksus Stream, but I would be concerned about their ability to mate and spawn in any dry body of water.  The water being low also makes it more difficult for large ungulates to safely go to the lake to drink and eat aquatic plants.  Coyotes are notoriously clever and know that with no cover and over jagged rock, the deer and moose have no chance near the water.

What I would like to see moving forward, would be for FERC to require Brookfield to submit impoundment level data for the last 30 years.  This would provide actual data to mine and others arguments.

I would also like to see an actual boat launch maintained yearly at both the Boom House and on Caribou Lake.  This would allow for recreation opportunities for all.

The lake needs to have navigational hazards marked with buoys at a minimum and make sure they are maintained yearly as well.  This will at least provide a modicum of safety and usability for the lake for those that may not have 30 years of experience on the lake.  This summer I went with friends that had never been and they remarked that they would never try to navigate that lake without someone who is familiar with it present.

I would also like the state biologists to perform spawning studies of brook trout and salmon to ensure they are still breeding and maintaining a healthy population.

Thanks for your time,

Owen Genest

**Subject:** **Ripogenus Hydroelectric Project (FERC No. 2572-133)**
**Penobscot Mills Hydroelectric Project (FERC No. 2458-247)**
**Comments on Scoping Document 1**

Dear Secretary Bose:

Great Lakes Hydro America, LLC (GLHA), a subsidiary of Brookfield Renewable and Licensee of the Ripogenus Hydroelectric Project and Penobscot Mills Hydroelectric Project (collectively referred to as the "Projects"), herein files comments on Scoping Document 1 (SD1).

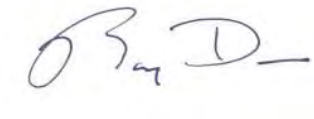
On June 11, 2021, GLHA filed the Notices of Intent and Pre-Application Document (PAD), which initiated the formal relicensing proceeding to obtain two separate new licenses for the continued operation of the Projects through the Federal Energy Regulatory Commission's ("FERC" or "Commission") Integrated Licensing Process (ILP). Based on the ILP regulations and the Process Plan and Schedule provided in the PAD, FERC issued SD1 on August 10, 2021.

Based on a review of SD1, GLHA submits the comments described below with new text shown in *italics* and deleted text shown in ~~strikethrough~~.

1. Page 14: GLHA notes a correction needed to the last sentence on page 14 regarding the Millinocket Development: "Water exits the turbines through seven, 25-foot-wide tailrace bays that discharge directly to ~~the West Branch~~ *Millinocket Stream and then flows downstream into Shad Pond and the West Branch*."

2. Page 16: GLHA notes the following clarification as it relates to the last paragraph on page 16 regarding the Dolby Development: "The power generated by the Dolby Development is transmitted to the grid via an adjacent substation that contains two transformers and a 2-mile-long transmission line that extends to GLHA's Substation #5 *(also referred to as the Powersville Substation) located adjacent to the East Millinocket Development*. *Additionally, a second transmission line extends approximately 5 miles from the Dolby substation to the former Millinocket Mill, but is currently out-of-service."*

3. Page 18: GLHA notes the following correction to the last sentence in the third paragraph on page 18 regarding the East Millinocket Development: "From the transformer, power is transmitted to Substation #5 *(also referred to as the Powersville Substation)* via a ~~2-mile-long~~ *2,000-foot-long* transmission line."



Great Lakes Hydro America, LLC
1024 Central Street
Millinocket, ME 04462
www.brookfieldrenewable.com
Tel: 207.723.4341
Fax: 207.723.3948

4. Page 20: GLHA notes the following clarification to the text in the second paragraph on page 20 regarding the Penobscot Mills Project recreation facilities: "The Green Bridge Boat Launch is located ~~at the Millinocket Development~~ *downstream of North Twin Dam on the West Branch of the Penobscot River and within the Penobscot Mills Project boundary. It provides boating access both downstream to Quakish Lake (Millinocket impoundment) and upstream to North Twin Dam*."

GLHA also notes that Table 4.2-1 of the PAD (page 4-2) should state that the Millinocket, Dolby, and East Millinocket Developments are located in Penobscot County.

If you have any questions regarding this information, please contact the undersigned at (207) 775-5605 or randy.dorman@brookfieldrenewable.com.

Sincerely,

Randall Dorman
Licensing Manager, Brookfield Renewable

Ryan Gerry, Hermon, ME.
I am Maine state resident and a regular recreational user of the West Branch of the Penobscot. This waterway is a tremendous resource. The camping and whitewater rafting/kayaking is among the best in the country.

The dry-way above Ripogenus dam is an untapped resource that holds great potential. Scheduled releases would be a major draw among the whitewater community and could potentially hold commercial value for guided raft tours. Please consider including scheduled dry-way releases for recreational use as a condition of the dam relicensing.

peter forti, norfolk, VA.
Project Number: 2572-133, Docket Number: P-2572 and Sub Docket Number: 133

As a long time land owner of 42 years, at the junction of lake caribou and ragged stream, I have witnessed the steady decline of water levels over the years at the early stages of summer and fall seasons. This has resulted in the loss of our recreational activities (ie: boating, canoeing, fishing, swimming etc…). It has also impacted wildlife as they use this area for their survival. Particularly Eagles, osprey, herons, loons  and other birds that rely on high water levels for their food supply, as well as land animals for drinking water.

As a tax payer, I am seeing diminishing use of the lake but increasing tax hikes with no communal services at all. The least GLHA can do is keep the water levels up till end September early October.
We all know that the more water pumped out the more money that Great Lakes Hydro America makes at our expense with no regard to anyone or anything or the lakes  they are depleting.

Therefor, I would also recommend that a forensic study be performed to evaluate this company's internal operating structure and procedures and determine if changes can be effected. If they continue to release water levels to bare minimums for profit, then we should be granted tax breaks??? However, I would be happy to pay my fair share of taxes if we can enjoy the land and lake, and all that it has to offer, that we originally paid for as it was intended for recreational purposes.

Therefore, before any license/permit is granted for the next 35 years I request that GLHA keep water levels at higher levels thru October of each year.
Maybe a request for additional bids should be requested?

Sincerely and on behalf of other surrounding owners.

Project Number: 2572-133, Docket Number: P-2572 and Sub Docket Number: 133

Alexandra L Horne, Oak Hill, WV.

Part 1:
As a director of the Maine Whitewater Championship whitewater kayaking race series in Maine, I help organize a race on the West Branch of the Penobscot each summer. I have held this role for three years, and am also an avid whitewater kayaker and registered Maine Guide. The Maine Whitewater Championship is one of New England's largest whitewater races, and brings recreational boaters to this iconic section of river every year for a weekend of paddling and community. Over the past two years participation has increased and we're seeing paddlers from different areas in the country travel to northern Maine to partake in this event.
I have personally seen the high esteem that whitewater enthusiasts from all over the country hold the West Branch of the Penobscot to. They love this river for its pristine beauty, clean water quality and phenomenal whitewater. This area is a hidden gem, with the local economy ready for the tourism that the Penobscot River and surrounding Baxter State Park can bring to the area. This wonderful natural resource we have could grow to be a popular destination for outdoor recreation, with the proper investment.
By adding recreational releases to the Dryway, a section of world-class class IV/V whitewater, an incredible stretch of navigable whitewater would become available to paddlers. This section contains quality whitewater that locals have paddled for several yeras. Adding days where increased flows could be released through the Dryway section of the Penobscot would draw more paddlers to the Penobscot and would benefit the area greatly. This section of whitewater has been paddled at several different flows, of which many paddlers have a favorite. A flow study would be beneficial to best determine a flow that would be appropriate for kayakers, rafters and fishermen alike, taking into consideration the optimal flows for natural inhabitants of the riverbed.
In addition, releases on the Backbend section and Millinocket Stream would allow for inclusion of recreational boaters looking for class II/III whitewater paddling in this area. These sections do not run often but are popular to those who have had an opportunity to experience them. Adding to the variety of difficulty that the Penobscot area offers, will support and allow recreational boaters of all skill levels a section of the river to enjoy.
Part II: Request for study of Dry Way section of whitewater below Ripogenus Dam

Goals: To better understand minimum flows required for kayak and raft passage

Objectives:
A)Obtain minimum CFS required for kayak and raft passage.
B)Obtain a ideal CFS for kayak and raft passage
C)Obtain a ideal flow for commercial rafting

Public Interest:
A)Finding flows that accommodate all experience levels of whitewater boaters.
B)Find flows that accommodate and support native fish habitat
C)Both public and private boaters will come to the area for recreational releases, boosting the local economy which is heavily reliant on outdoor recreation.

D)Add to the iconi class IV/V section of the West Branch of thye Penobscot by 1 mile.

Existing & needed Information
B) Need proof that dryway is navigable
C) Create info about the difficulty of the whitewater according to flow that is available for all recreational boaters.

Proposed Methodology:
A) Schedule a day or days where Brookfield Releases 300,500,1000,1500,2000,3000cfs out of Ripogenus Dam for observation of best flows. Announce this day to allow kayakers, rafters and professional safety to be available and present to assess rapids and hazards at all flows.
C) Have a meeting and survey conducted to organize results.

Thank you for your time,

Alexandra Horne, OD FAAO

andrew s taber, South Dartmouth, MA.
To whom it may concern.

I Andrew Taber am writing to you today in regards to the watershed of chesuncook, ripogenus, and caribou lakes. I am a camp owner with a cabin on ripogenus lake. I have about 600ft of lake frontage on the lake. Due to the water level being around 22 ft low on a vertical scale the shore line is about 400 ft from the spring high water mark. I have built a dock two years ago and have not been able to use the dock due to extreme low water levels. The spring of 2021 the lake system was 7ft low on the vertical and for some reason was not allowed to brought up to the spring high level. With ripogenus damn being up for a new lease hopefully there will be literature from FERC to have regulations of the draw of the water from this lake system that can be managed better with the conditions that we all face with these changing times. The boat ramps on the lakes are at this time boarder line un useable. The chesuncook boat ramp is about 400 ft from spring high water. To access the water one needs to drive down the lake bottom over rocks and shale. There is no sign of there being a kept up boat ramp at this spot which should be serviced yearly. The caribou lake boat ramp is by no way any better. The public camp sites that are located remotely along the lakes are on average 200 ft from the lake. This makes for the usage of these sites to be a hazard to personal injury and also to ones boats and or canoes. The passage from the shorelines to each site offers different difficulties including grasses covering the jagged lake bottom, sand, silt, and mud. Rocks and shoals are a hazard to boats and boat motors. There are rocks sticking out of these lake that are normally under spring high water conditions that are normally 20ft under water. This is extremely dangerous even for the seasoned veteran of these lakes. Property values have been impacted as usage in the summer offer little to no lake access du to extremely low water levels. FERC needs guidelines to limit the over usage of a precious recourse needed and used from all the landowner, animals, fish species, plant species and the public that frequent this beautiful place in the state of Maine.

*Via Electronic Submission* (http://www.ferc.gov/docs-filing/ecomment.asp)
Ms. Kimberly D. Bose
Secretary
Federal Energy Regulatory Commission
888 First Street NE, Room 1A
Washington, DC 20426

**RE: Ripogenus Hydroelectric Project (P-2572-133)**

Dear Ms. Bose:

This submission is offered on behalf of William Cushing ("Mr. Cushing") and Allagash Gateway Campground ("Allagash Gateway") in response to the request of the Federal Energy Regulatory Commission ("Commission" or "FERC") for information, comments, and study requests related to the Ripogenus Hydroelectric Project (P-2572-133) (the "Project").

Mr. Cushing is a director of Andre Emerson Cushing Corporation, the majority landowner in T3 R12 WELS. Approximately 80% of Ripogenus Lake and 20% of Chesuncook Lake are within the boundaries of T3 R12 WELS. Mr. Cushing is a year-round resident of T3 R12 WELS, and his home is on Ripogenus Lake.

Allagash Gateway is a four-season sporting camp located on Ripogenus Lake near the Chesuncook Dam Point Boat Launch. It offers a private boat launch, canoeing, campsites, lodging, guide services, and a small store. During the summer months, Allagash Gateway's clientele are primarily interested in boating and fishing the lakes that make up the Ripogenus impoundment.

As more fully set forth herein, Mr. Cushing and Allagash Gateway have faced dire consequences based on the unregulated elevation of the Ripogenus impoundment. Specifically, boaters and anglers are unable to access Ripogenus, Chesuncook, and Caribou Lakes, thus precluding certain recreational opportunities in the region, negatively impacting the ability of Allagash Gateway to conduct its business and driving down the economy of this rural area.

## A. Recreational Opportunities in the Ripogenus Impoundment

Great Lakes Hydro America, LLC ("GLHA"), a subsidiary of Brookfield Renewable and Licensee of the Project, submitted its Pre-Application Document ("PAD") on June 11, 2021. In the PAD, GLHA expressly recognizes that "[r]ecreation represents one of the most important economic drivers for the region." (PAD, Section 5.8.1).

These recreational opportunities, as discussed in the PAD, include (a) FERC-approved Project recreation sites, (b) formal and informal non-project recreation sites, and (c) commercial recreational opportunities.

### a. FERC-approved Project recreation sites

The PAD recognizes that "[t]he Ripogenus Project has several formal FERC-approved Project recreation sites which provide opportunities for fishing, swimming, boating, hunting, ice fishing, camping, hiking, snowmobiling, canoeing, cross-country skiing, waterskiing, sailing, and sightseeing. These include one boat launch, one boat put-in, several campsites, rafting put-in facilities at McKay Station, and one trail (Table 5.8-1 and Figure 5.8-3)." (PAD, Section 5.8.2.1).

Among these FERC-approved Project recreation sites is the Chesuncook Dam Point Boat Launch. This launch is located on the Ripogenus impoundment (Chesuncook Lake basin) on Chesuncook Lake Road off the Golden Road. It is a single-lane gravel boat launch, with parking for multiple trailered vehicles. It was established as a requirement of the 1996 FERC License, and it is managed by the Penobscot River Corridor.

### b. Non-project recreation sites

The Project and surrounding areas also provide vast amounts of recreational opportunities utilizing both formal and informal non-project recreation sites. Along the Golden Road, which follows the Ripogenus impoundment (Chesuncook Lake), there are many informal recreation sites and pulloffs that provide public access to Project lands and waters. This is also true for the impoundment itself. With vast areas of undeveloped lake and riverfront, recreational users within the Project area frequently utilize informal recreation sites along the shoreline and within the drawdown zone, and they use informal beach areas for swimming, picnicking, fishing and camping.

### c. Commercial recreational opportunities

While the most widely discussed commercial recreational opportunities within the Project and surrounding areas pertain to the whitewater rafting industry, there are multiple commercial recreational opportunities outside of the rafting industry. One such opportunity is Allagash Gateway, which provides lodging and guide services to anglers in the Maine North Woods. Like the whitewater rafting companies, Allagash Gateway is dependent on the water system of the Ripogenus impoundment to serve its recreational clientele.

## B. Effect of unregulated elevation of the Ripogenus impoundment on Recreational Opportunities

The unregulated elevation of the Ripogenus impoundment has had a negative effect on the recreational opportunities within the Project and surrounding areas.

As set forth in the PAD, "[t]he Ripogenus Project operates as a store-and-release facility with an annual seasonal drawdown that allows for management of water levels and flows downstream of the project. The normal full pond elevation of the Ripogenus impoundment is 941.6 feet, with a

maximum drawdown of 44 feet (based on operational limitations of the project)." (PAD, Section 3.1.3).

According to the PAD, "[d]uring normal operation and normal inflow years, the Ripogenus impoundment elevation is held relatively stable at 941.6 feet during the summer months and is gradually drawn down starting in the fall, with a target low elevation of 913.6 feet by late winter, in anticipation of spring thaw and high flows. This operation results in a target seasonal drawdown of 28 feet." (PAD, Section 3.1.3).

Mr. Cushing has resided year-round on Ripogenus Lake for more than a decade. In the 11 years that he has been a year-round resident, he has witnessed a draw down each summer of approximately 15 feet. Thus, if the normal full pond elevation is 941.6 feet by late spring, the Ripogenus impoundment is down to 926.6 feet within three months thereafter.

In 2021, the three-month summer draw down was the usual 15 feet; however, the Ripogenus impoundment did not start at normal full pond elevation of 941.6 feet in late spring. Rather, the impounded started at a 10-foot deficit, closer to 931 feet.

From the very start of the 2021 fishing season, this 10-foot deficit has wreaked havoc on the recreational opportunities within the Ripogenus impoundment.

Specifically, the National Resource Education Center hosted the annual Chesuncook Lake Salmon Derby (the "Derby") on May 29 and 30, 2021. The primary purpose of the Derby is for anglers to harvest salmon under 16 inches to thin out the over-abundant population that dominates the lake. In addition to being a useful fisheries management tool, the Derby is an economic driver, bringing anglers to the region for a weekend event.

This year, Derby participants were hampered by low water levels. The Chesuncook Dam Point Boat Launch was not a viable option for launching boats into Chesuncook Lake, since water levels were still too low to put in a boat at that location.

Fortunately, Allagash Gateway got just enough rain to put in its docks on May 28, 2021, just one day prior to the Derby. Absent the fortuitous rainfall, and without Allagash Gateway providing access via its private boat launch, the Derby would not have been able to take place as scheduled.

Unfortunately, the fishing season was short lived. Boaters were able to use the Chesuncook Dam Point Boat Launch for a brief period of time during the month of June 2021, but that was it. The last attempted boat launch (which was unsuccessful) took place on July 6, 2021. By then, water levels were already too low to access Chesuncook Lake at the public launch.

Allagash Gateway was able to provide access to Ripogenus Lake for a short period of time thereafter, but by the end of July, Allagash Gateway had no choice but to pull its docks for the season because water levels had continued to decrease. Allagash Gateway had to face disappointed clientele who came to fish, some even trailering boats long distances, only be told that there was no way to launch their boats within the Ripogenus impoundment by August. Other clientele, who historically came every year to fish in mid-to-late summer and early fall, canceled their reservations as a direct result of the inability to launch their boats. For a campground that is dependent on anglers during the summer months, this was devastating on all levels.

**Current Elevation of the Ripogenus Impoundment**

As of September 8, 2021, the Ripogenus impoundment was down 28 feet from the normal full pond elevation, to approximately 913 feet. With seven months of draw down left to go, the elevation levels are of great concern. The following are photographs of recent current conditions, along with a Google Maps image included for context.

Photo 1:

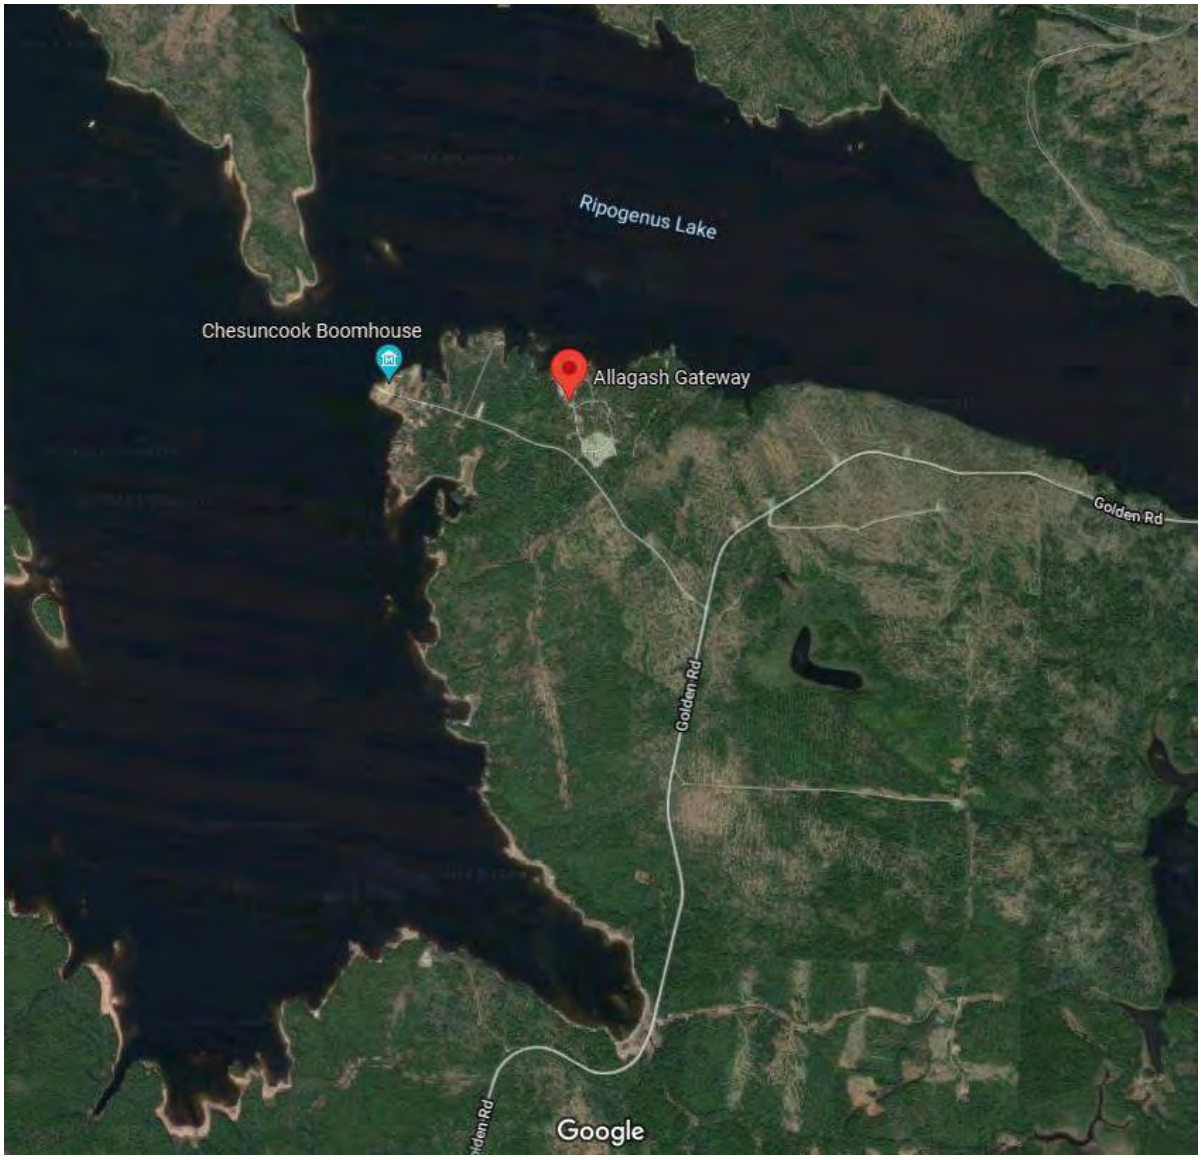

Photo 1 is a Google Maps image depicting the location of Allagash Gateway and its surrounding area. The Chesuncook Dam Point Boat Launch is just to the south of the Chesuncook Boomhouse. The channel between Ripogenus Lake and Chesuncook Lake is to the north of the Chesuncook Boomhouse. Mr. Cushing's house is on Ripogenus Lake between the Chesuncook Boomhouse and Allagash Gateway. The south cove of Chesuncook Lake, as depicted in Photo 11, is at the bottom center of the image.

Photo 2:

Photo 2 was taken on September 8, 2021. It depicts the marina at Allagash Gateway. The docks were pulled out at the end of July. Mr. Cushing, who took the picture, was standing in an area that should be covered in water.

Photo 3:

Photo 3 was taken on September 8, 2021. It depicts the marina at Allagash Gateway. Mr. Cushing, who took the picture, was standing in an area that should be covered in water. The high water mark is visible above the canoes on the right.

Photo 4:

Photo 4 was taken on September 8, 2021. It depicts the Chesuncook Dam Point Boat Launch. Mr. Cushing, who took the picture, was standing at the high water mark. He estimates that it was approximately 80 yards from the high water mark to the edge of Chesuncook Lake.

Photo 5:

Photo 5 was taken on September 17, 2021. It was taken from the west end of the channel between Ripogenus Lake and Chesuncook Lake depicts and depicts Mr. Cushing's house. The high water mark is the tree line in front of his house.

Photo 6:

Photo 6 was taken on September 17, 2021. It depicts Mr. Cushing's house in the upper left corner, from the west end of the channel between Ripogenus Lake and Chesuncook Lake. There should be 10 additional feet of water in the channel, covering all of the rocks.

Photo 7:

Photo 7 was taken on September 17, 2021. It depicts the west end of the channel between Ripogenus Lake and Chesuncook Lake, looking east with Spencer Mountain in the background.

Photo 8:

Photo 8 was taken on September 17, 2021. It depicts the west end of the channel between Ripogenus Lake and Chesuncook Lake, looking east with Spencer Mountain in the background. The rocks on the right of the photo are from the old dam.

Photo 9:

Photo 9 was taken on September 17, 2021. It depicts the west end of the channel between Ripogenus Lake and Chesuncook Lake, looking north.

Photo 10:

Photo 10 was taken on September 17, 2021. It was taken in front of Mr. Cushing's house and depicts the west end of the channel between Ripogenus Lake and Chesuncook Lake.

Photo 11:

Photo 11 was taken on September 27, 2021. It was taken from the Golden Road and depicts the Chesuncook Stream outlet at the southernmost point of Chesuncook Lake. The entire south cove of Chesuncook Lake is dry.

**C. Coordination with Upstream Storage and Requested Studies**

The Ripogenus impoundment elevation is based on a number of factors: "In the spring, the Ripogenus impoundment elevation rises based on inflows from the upstream Storage Project No. 2634, spring thaw, and precipitation, with the goal of reaching 941.6 feet by late spring." (3.1.3).

Mr. Cushing and Allagash Gateway would like to see better coordination with upstream Storage Project No. 2634, particularly in years following a drought or below-normal snowfall levels, to ensure that the Ripogenus impoundment elevation reaches normal full pond elevation of 941.6 feet by late spring and is held relatively stable at 941.6 feet during the summer months. Rather than have this be a "goal" of GLHA, Mr. Cushing and Allagash Gateway would like to see it be a condition of renewal and a license requirement.

To that end, Mr. Cushing and Allagash Gateway would request a review of studies and/or data for the last 10 years for the Ripogenus impoundment showing the high level elevation in late spring, the elevation following the three-month summer draw down, and the low level elevation in winter.

Mr. Cushing and Allagash Gateway understand that Ripogenus Project operators balance downstream flows and water levels to support flood control, public safety, dam safety, supplemental flows during seasonal low-flow periods, fish spawning and migration, recreation and whitewater boating, water quality, and generation needs, but this cannot be to the detriment of those who rely on adequate impoundment elevation for recreational opportunities, which opportunities GLHA expressly admits represent one of the most important economic drivers for the region.

Accordingly, Mr. Cushing and Allagash Gateway would request that GLHA conduct a study on the impact of its draw downs on recreational opportunities in the Ripogenus impoundment and the corresponding effect of any resulting limitations on the economic climate within the region.

Thank you for your time and consideration.

Yours truly,

*/s/ Allison A. Economy*

Allison A. Economy

Benjamin Koehler, Orono, ME.
Hello, my name is Benjamin Koehler, lifelong Mainer, and Whitewater Guide on the West Branch of the Penobscot. I am writing today concerning the relicensing of the Ripogenus Dam, the Millinocket Stream Dam, and the Penobscot Mills projects. Each of these projects regulates the flows for sections that have significant recreational, aesthetic, and cultural resources.

Below the Ripogenus Dam is the Dryway, some of the best class 4/5 whitewater in the northeast. The Dryway is dewatered by the operation of McKay Station and currently has no release schedule. Millinocket Stream has several miles of quality class 2 and 3 whitewater, perfect for teaching beginners, and it conveniently ends right in Millinocket. There is currently no release schedule on this section, and much of the water is pumped from Millinocket Lake into Pemadumcook Lake to be used in the Penobscot Mills projects. The Backbend (the dewatered section between Quakish Lake and Dolby Pond) has excellent wilderness character despite being close to town, a long class 3 rapid, and a 10 foot waterfall that is a significant aesthetic and recreational resource. This section currently has no release schedule, and almost never runs from natural flow due to the water being used by the hydro project at the Millinocket Mill site.

Video detailing the quality whitewater of the Dryway:
https://youtu.be/t0Q_nXOTmSY?t=929

I would like to request a whitewater boating flow study on each of these 3 sections.

The goal of these studies would be to find the minimum boatable flows for whitewater recreation, the ideal flow for whitewater recreation, and the high water limit for whitewater recreation. This information would guide FERC in establishing a sensible release schedule for these sections.

I am not a resource management agency.

These studies would meet the whitewater community goals of having quality class 5 whitewater (The Dryway), safe class 3 whitewater (The Backbend and Millinocket Stream), all within a short drive from Millinocket.

There have not been whitewater boating flow studies on these sections, so the existing knowledge is the experience of the local boaters who have run these sections. The studies would combine this knowledge with new boaters' impressions of the rapids, giving us information about the rapids at a variety of levels, from a variety of perspectives.

Each of these hydro projects directly regulates the flow downstream of the project.

The dewatering of the Dryway, Backbend, and Millinocket Stream renders the recreational resources unusable, as the minimum flows as stated by the current licenses are not high enough to be boatable. These studies would inform FERC in establishing a release schedule that would make these resources available for the public to enjoy.

Dryway: Gather boaters to run the section at a variety of flows; 1200 (CFS), 1600, 2000, 2400, 2800, 3200. This flow range covers what we know to be the runnable levels for this section. After all the levels have been run, the participants convene to take a survey to gather their impressions.

Millinocket Stream: Gather boaters to run the section at a variety of flows; 400 (CFS), 600, 800, 1000, 1200, 1400. After all the levels have been run, the participants convene to take a survey to gather their impressions.

Backbend: Gather boaters to run the section at a variety of flows; 1200 (CFS), 1600, 2000, 2400, 2800, 3200. This flow range covers what we know to be the runnable levels for this section. After all the levels have been run, the participants convene to take a survey to gather their impressions.

Each of these studies could be accomplished in one day, at a low cost as the whitewater boaters will volunteer their time. American Whitewater often has a role in organizing these flow studies, and can get a sufficient number of volunteers to participate.

-Thank you for your time

Benjamin Koehler

October 7, 2021

Kimberly D. Bose
Secretary
Federal Energy Regulatory Commission
888 First Street, N.E. Washington, DC 20426

RE: Comments on the PAD for Ripogenus Hydroelectric Project (FERC No. 2572) and Penobscot Mills Hydroelectric Project (FERC No. 2458) from the Caribou and Chesuncook Lake Camp Owners Association and the Chesuncook Dam Camp Owners Association.

Dear Secretary Bose:

On behalf of the members of the Caribou and Chesuncook Lake Camp Owners Association and the Chesuncook Dam Camp Owners Association, I am submitting these comments on the Pre-application Documents (PAD) for the Ripogenus Project (P-2572) and the Penobscot Mills Project (P-2458) filed for Great Lakes Hydro America, LLC by Brookfield Renewable ("Brookfield") dated June 11, 2021.

The two Associations represent over fifty camp owners with a significant and substantial interest in the relicensing of these projects. We have a deep love for and knowledge of, Caribou, Chesuncook, and Ripogenus Lakes, all natural lakes interconnected and level controlled by Ripogenus Dam. We all have a large financial and time commitments to our properties. Many of our members have long multi-generational histories on the lakes and know them well before and after the current operator and applicant. It is our observation that Brookfield Renewable is operating Ripogenus Dam vastly differently than it was operated for its previous eighty-year history and now believe that lake level parameters are necessary for the health of the lakes, the aquatic species that inhabit them, as well as the recreational use of the lakes.

The most obvious sign of a significant change in operation and evidence of long-term lake drawdown during the growing season, and the corresponding recreation season from what is traditionally Memorial Day weekend to the end of September, is the complete transformation of the littoral zone to full primary succession. Compared to the last relicensing, when the littoral zone would be rocky shore and exposed lake bed, there are now, in many places hundreds of feet of grass and other primary succession plants. There are willows and alders growing far from the high-water line. We are sensitive to the drought of the last year but these changes are the direct result of a continuous and persistent drawdown.

*Figure 1 Littoral Zone Chesuncook Lake*

This is in contrast to the PAD which states;

*During normal operations and normal inflow years, the Ripogenus impoundment elevation is held relatively stable during the summer months and is gradually drawn down starting in the fall with a target low elevation by late winter in anticipation for the spring thaw and freshet.*

Stable lake levels near full pond level during the recreation season are the norm throughout impoundments all across Maine. The North Twin Lakes are required to be within one and a half feet of full pond from Memorial Day until the end of August and no more than 3.5 feet by October. Other lakes in Maine have similar drawdown restrictions. According to the PAD, Chesuncook Lake can be drawn down up to 44 feet from full pond at any time of the year, which is not a permit restriction merely a design restriction. For the past two recreational seasons the lakes in the Ripogenus Impoundment have seen drawdowns of approximately 20 feet by Labor Day which had significant negative impacts across all uses of the Lakes.

The boat launches become almost unusable, there are numerous navigational hazards, boat travel between Caribou, Ripogenus and Chesuncook Lakes becomes impossible, docks and moorings are dry, water lines to our camps are dry, and camps and campsites are hundreds and in a few

cases thousands of feet from the water. It is not hard to imagine that there is a significant loss to property values with large drawdowns during the recreational season. We understand that during a drought year full pond levels are more difficult to maintain, but there have been many days that flows from Ripogenus Dam far exceeded the minimums required for downstream commitments to the rafting industry and for fisheries. We observe that no matter what the hydrological conditions, the lakes are in a perpetual state of drawdown other than at spring freshet.

Additionally, there have been multiple years over the last twenty years when the lake never reaches full pond after the spring freshet. We understand that there will be times of near full pond given factors out of the applicants control but instead of a target drawdown of 28 feet as stated in the PAD,

*Normal full pond elevation of the Ripogenus impoundment is 941.6 feet with a maximum drawdown of 44 feet (based on operational limitations of the Project). During normal operations, the Ripogenus impoundment is maintained between normal full pond elevation (941.6 feet) following seasonal inflow to the impoundment and a target elevation of 913.6 feet prior to the seasonal inflow, which equates to a target seasonal drawdown range of 28 feet.*

drawdown should be targeted to a full pond in the spring based on the current snowpack as reported by Maine's detailed and weekly snow survey and historic averages of spring rains. This past year and others the lake has been down significantly at Memorial Day.

We also question the PAD's assertion that;

*In response to the filing of the periodic recreation monitoring reports, FERC concluded that the facilities at the Ripogenus Project <u>are meeting the needs of the public</u> and that the Project does not require additional recreation facilities (FERC 2002, 2009, 2015).*

given that both the Caribou and Chesuncook boat launches have not been maintained in years and are in reality nothing more than rocky paths to the water that often become unusable at the lake levels we have seen under the current applicant's operation of Ripogenus Dam. We would ask the FERC require standards for the boat launches and required annual maintenance for them.

*Figure 2 Chesuncook Lake Boat Launch, September 2021*

We believe that many of the studies and data collected for the previous relicensing are totally out of date given the change in operation and the extremely low lake levels we have seen. Therefore, we fully support the requests of NOAA, US Fish and Wildlife, Maine Inland Fisheries and Wildlife, and others that the applicant provide impoundment and flow data. We ask that current studies be made to fully access current conditions including and not limited to

- Reservoir Water Level Fluctuation/Operation Model Study
- Reservoir Surface Area Assessment Study
- Shoreline Management Assessment Study
- Recreation Study that includes both lake and river use
- Littoral Habitat Assessment Study

We also believe that the current Use Attainability Analysis (UAA) for the Ripogenus impoundment was based on data that is out of data where a summer recreation season drawdown was only 3.5 feet on average. With current drawdowns far exceeding that average, the UAA needs to revisited and updated.

There may well be further studies needed based on the conditions of the Lakes and River today so that an appropriate permit may be issued that meets the needs of the applicant as well as the people of Maine, and we encourage FERC to ensure those are done as well.

Thank you for the opportunity to provide our initial comments on the PAD.

Respectfully,

Bill Houston

bhoustonps@gmail.com

Earle R Fayle, Medway, ME.
I have been a camp owner on Ripogenus Lake since 2000 and have had a camp in the family on Chesuncook Lake since 1965. The water levels on the lakes have been very inconsistent and in the past 2 years have been excessively low.
The ecological impact on the watershed as well as the recreational activities have been negatively impacted. Navigational hazards, boating opportunities, ability to dock and non-potable water use have been a problem due to low water levels. GLHA has to do a better job of maintaining water levels at a higher mark. I realize it is a balancing act dealing with flows but more consideration has to be taken for camp owners in the watershed.

Sincerely,

Earle Fayle

October 7, 2021

Dear Secretary Bose:

My name is Jeff Fayle and I am writing in reference to docket # 2572. I have been a part-time resident at Chesuncook Lake for 59 years. As a youth, my family spent summers and weekends there. As an adult, I have spent an average of 7 - 8 months of the year in residence at the lake. Chesuncook is my home, and I am writing to document my concerns regarding the fluctuating water levels that result from the operation of Ripogenus Dam.

The Electric Consumer Protection Act of 1986 required FERC to give *BALANCED* consideration to both the developmental and non-developmental values in the hydro licensing process. In addition, the relicensing process is required to include a detailed environmental assessment of the impacts on fish and wildlife habitat, water quality, land use, and recreation, as well as other areas of concern. Yet to my knowledge the last assessment was completed in 1996. GLHA claims in the PAD that no significant changes have occurred since the previous relicensing. However, I can assure you that the changes to Chesuncook since 1996 are vast and transformational to the ecology and dynamics of the lake. I will break down my concerns into four categories:

1. Ecological Changes

2. Navigational Access and Safety

3. Impacts on Fishing and Recreation

4. Personal Observations

**ECOLOGICAL CHANGES DUE TO FLUCTUATING WATER LEVELS**

Low Water Levels: For over 50 years my family moored boats in a sheltered cove near my camp. This possibility has become increasingly limited since the cove is often completely devoid of water. The cove previously had a rocky bottom, but with the continuous seasonal drawdowns, it has become a field. I am including two photos of the cove to show the change in ecology over the past 20 years.

The cove where I moored my boat.

Looking back at the water, so far away

High Water Levels: Here are examples of the high water levels being exceeded. In the photo below, high water in spring deposited driftwood up over the riprap and then eroded the grass and soil underneath.

In the next photo, excessive water levels in winter caused ice to completely re-shape the shoreline, raising it 14”.

**NAVIGATIONAL ACCESS AND SAFETY**

Access between the lakes: When the water levels are excessively low, it creates navigational hazards and lack of access. There are years when it has become nearly impossible to navigate between the lakes.

The photo above shows the passageway between Chesuncook and Ripogenus. The passage is strewn with so many exposed ledges as to render it nearly impassable.

But even worse is the passageway between Chesuncook and Caribou. Circled in the photo above is a canoe that eventually needed to be hauled through the channel. *Photo from 2020.*

Navigational Safety: Within each individual lake we see ledges that were previously underwater but are now creating serious safety concerns for boaters and recreational users. As the water draws down, the ledges and rocks move continuously closer to the surface, and are being struck by recreational users, damaging their boats. I fear it is just a matter of time until someone is seriously injured. Public safety needs to be a priority. Rather than wait for tragedy to strike, we need to be proactive.

**RECREATIONAL AND FISHING ACCESS:**

Recreational Access: People come from all over the country to canoe down the upper West Branch into Chesuncook Lake. These travelers depend on State campsites that are located along the way, but the drawdowns limit access to these campsites. This year, the State could not safely reach the campsites by boat and eventually pulled their boat before the normal end of their season.

Fishing Access: Chesuncook is blessed with many major tributaries which are considered prime fishing in September. But the excessively low water levels greatly limits access to these traditional fishing holes by rendering access to them impassable during September. The photo below is of a well-known fishing spot along a tributary that was rendered inaccessible from Chesuncook during September.

**PERSONAL PERSPECTIVES**

Moorings: I mentioned previously about the drastic ecological changes in the cove where I moored my family moored boats for 50 years. I have included a photo of the three boat moorings I placed in the cove over that time period. Mooring #1 was used for years without difficulty. Then the water levels gradually dropped, so I added mooring #2. Those two moorings continued to suffice for many more years. More recently I added mooring #3. Now all of these moorings are out of water because the cove is dry. When this happens, I need to pull my boat. Once pulled, it is very difficult to relaunch for an outing because the “public landing” is nearly impassable.

Dock: It is a constant struggle to continuously relocate the dock as the water levels recede. The water level is down 20+ feet, and the drop off to the dock is so steep now, it is actually treacherous to attempt to utilize the dock.

It is a long way up a steep rocky slope.

Winter Shoreline damage: The shoreline damage caused from excessive high water impacted my camp property. The photo below depicts how the shoreline was pushed up by ice expansion during the winter - 14".

And the picture below shows the result of the changes to the shoreline - the damage to my brick fireplace - raised, cracked, with many loose bricks behind it. I removed this fireplace and replaced it.

In closing: To my knowledge, during the last relicensing no one represented the camp owners. We did not envision the impacts these water level fluctuations would have on the ecology, navigation, safety, fishing and recreation. We have each been affected in a personal way and surely our camp valuations and marketability are lowered. We need a littoral zone study. In addition, GLHA needs to release all requested water level and flow data since the previous relicense, not just a summary. **Regulation cannot happen without transparency.**

Sincerely,

Jeff Fayle

**RE: Pre-Application Document Comments, Study Requests, and Scoping Document Comments for the Ripogenus (FERC No. 2572-133) and Penobscot Mills (FERC No. 2458-247) Hydroelectric Projects**

Dear Secretary Bose:

This responds to the Pre-Application Document (PAD) for the Ripogenus and Penobscot Mills Hydroelectric Projects (collectively referred to as Projects), located on the West Branch of the Penobscot River and Millinocket Stream in Piscataquis and Penobscot Counties, Maine. The PAD is being provided in preparation of an application for a new federal license for the Projects. The United States Fish and Wildlife Service (Service) offers the following comments based on the PAD (submitted to us by Great Lakes Hydro America, LLC [GLHA] on June 11, 2021) and information we obtained at the Federal Energy Regulatory Commission (Commission) virtual scoping meeting and site visit held on September 09, 2021.

*PRE-APPLICATION DOCUMENT*

**PROPOSAL**

Ripogenus

The Ripogenus project consists of a 795-foot-long, 83-foot-high concrete gravity dam, topped by two concrete ogee spillway sections totaling approximately 480 feet in length, which creates a 29,270-acre impoundment extending approximately 20.8 miles upstream with a normal full pond elevation of 941.59 feet United States Geological Survey (UGSS) datum. Ripogenus, Caribou, and Chesuncook Lakes as well as Black, Brandy, and Moose Pond are all part of the impoundment created by the Ripogenus dam. According to GLHA, the impoundment's usable

storage is about 688,705 acre-feet with a maximum drawdown of 44 feet, to an elevation of 897.59 feet.

Water flows from the Ripogenus impoundment through a concrete intake structure that consists of trashracks with 2-5/8 inch clear spacing, and there are three vertical Francis turbines at the project. The intake structure connects to 16-foot-diameter concrete-lined tunnel that is approximately 3,850 feet long and connects to three penstocks that lead to the powerhouse (i.e., McKay Station). Flows diverted to the tunnel, penstocks, and powerhouse bypass a 0.75-mile-long river reach, the Upper Gorge, of the West Branch. The 130-foot-long by 45-foot-wide powerhouse contains three vertical Francis-type turbines, each connected to a generator. Flow from the powerhouse is conveyed back to the West Branch via a 50-foot-long excavated bedrock tailrace.

The Ripogenus project contains one utility-scale battery energy storage site.

Penobscot Mills Project

The Penobscot Mills project consists of four hydropower developments and one storage development: North Twin, Millinocket, Dolby, East Millinocket, and Millinocket Lake Storage which is located on Millinocket Stream.

*North Twin Development*

The North Twin Development consists of a 1,051-foot-long concrete and earth-filled structure at the outlet of Elbow Lake. The dam includes a 114-foot-wide intake structure and powerhouse, a 34-foot-wide fishway for resident fish species, a 117-foot-long tainter gate section, and a 286-foot-long earthen embankment. In addition to the dam, there are six dikes, totaling 2,530 feet in length, upstream of the dam, which retain water. The North Twin impoundment includes Elbow, South Twin, North Twin, Pemadumcook, and Ambajejus Lake. The impoundment is approximately 11.8 miles long and has a surface area of approximately 17,790 acres at the normal full pond elevation of 491.92 feet. According to GLHA, the impoundment's usable storage is about 344,355 acre-feet with a drawdown of 22 feet.

Water flows from the North Twin impoundment through an intake structure to the powerhouse. The intake contains nine water passages, each 8 feet wide by 13 feet high and equipped with a steel gate to control the flow of water to the turbines. The intake is protected by trash racks with 2-5/8-inch clear bar spacing. Water exits the powerhouse through six tailrace bays and flows through a 104-foot-wide tailrace back into the West Branch. There are two vertical fixed blade turbines and one vertical Kaplan turbine at the project.

*Millinocket Development*

The Millinocket Development consists of a 1,262-foot-long concrete dam (referred to as Stone dam) located at the outlet of Quakish Lake which consists of a 300-foot-long overflow spillway section with no flashboards, a 358-foot-long spillway section with 30-inch-high flashboards, a 428-feet, five-inch-long spillway with a two-foot, nine-inch-high rubber, inflatable dam. The

dam itself directs water into a canal which is 150-feet-wide by 1,400-feet-long and leads to Ferguson Pond. The trashracks for the six 10-foot diameter penstocks have a clear spacing of 2-7/8 inches, while the trashracks for the single 11-foot diameter penstock have a clear spacing of 2-1/2 inches. There are eight horizontal Francis turbines at the project.

*Dolby Development*

The Dolby Development consists of a 1,395-foot-long concrete and earth-filled structure located at the outlet of Dolby Pond, a 27-foot-long concrete abutment, four spillway sections, a 76-foot-wide waste gate, a 209-foot-wide intake with an integral powerhouse, and two contiguous earthen dikes measuring 300 feet long and 250 feet long. Water is drawn from Dolby Pond through a 23-foot-wide by 209-foot-long concrete intake structure with nine openings. Each opening is equipped with a headgate to control the flow of water to the turbines. Eight sets of trashracks, having a total length of 174 feet, extend across the upstream side of the intake. The trashracks for bays 2 through 4 have a clear bar spacing of 1-5/8 inches, and the trashracks for bays 5 through 8 have a clear bar spacing of 2-5/8 inches. Water flows from the intake to a 115-foot-wide by 167-foot-long powerhouse that contains four operable turbine-generator units (Units 5, 6, 7, and 8). Units 1,2,3, and 4 are out-of-service according to GLHA and do not currently contribute to the development's rated capacity. Three of the operable turbines are inclined Kaplan units and one is a fixed blade unit.

*East Millinocket*

The East Millinocket Development is located approximately 1.7 miles upstream of the Medway project (FERC No. 2666) and consists of a 717.5-foot-long structure with two spillway sections measuring 366 feet, a 59-foot-wide waste gate structure. The impoundment extends from the dam 1.9 miles upstream to the tailwater of Dolby. The surface area of the impoundment is 128 acres at normal pull pond elevation of 287.2 feet. The intake contains 12 gate openings that lead to 6 covered flumes in which the turbines are located. Trashracks are located immediately upstream of the gate openings and have 1-1/4-inch clear spacing between the bars. The powerhouse contains six horizontal Francis turbines.

*Millinocket Lake Storage Development*

The Millinocket Lake Storage Development consists of a 635-foot-long concrete and earth-filled dam located at the outlet of Millinocket Lake. The dam includes a 19-foot-long spillway section and an adjacent 58-foot-long gated section that contains four lift gates and one log sluice gate. The normal full pond elevation of the lake is 480 feet with a surface area of approximately 8,640 acres. According to GLHA, usable storage is 45,370 acre-feet with a 6.2-foot drawdown. The development's pumping station, which contains two pumps, is located on the west side of Millinocket Lake, about 6.2 miles from Millinocket Lake Storage Dam. Water is conveyed from the pumping station through two 544-foot-long, 4-foot, 6-inch-diameter steel pipes, which is then discharged to Ambajejus Lake through an outlet structure. According to the PAD, the Millinocket Development contains seven operable (Units 1, 3, 4, 5, 6, 7, and 8) and one inoperable (Unit 2) horizontal Francis turbines. GLHA describes Unit 2 as out out-of-service, but it "routinely evaluates rehabilitation of the unit based on market conditions and other factors."

Protection, Mitigation, and Enhancement Measures

Outside of providing flows for increased angling opportunities, landlocked salmon habitat, and whitewater rafting as well as deployment of nesting platforms for loons and other aquatic birds, and operation and maintenance of an upstream fishway at the North Twin Development for resident species, GLHA has proposed no additional protection, mitigation, or enhancement (PME) measures at Ripogenus, North Twin, Millinocket, Dolby, East Millinocket, or Millinocket Lake Storage.

## COMMENTS

*PAD COMMENTS*

### 4.3 Existing Project Facilities

GLHA provided a detailed description for each of the six dams; however, several important pieces of information are missing and should be provided to the agencies:

- a thorough description of how project operations are monitored and recorded;
- the minimum hydraulic capacities, runner diameters and runner speeds of all turbines (those in operation and those currently deemed out-of-service) at each dam;
- the calculated approach velocity at the trashracks/intakes (based on the wetted trashrack area); and
- how the Applicant intends to operate each development for the duration of any new license issued.[1]

### 4.4 Project Operations

Currently, it is unclear how GLHA operates the Projects as operations data was not provided in the PAD and is not available to the public, as discussed at the September 9, 2020 scoping meeting.[2] On September 13, 2021, the Service asked the Commission to require the Applicant to provide stakeholders with ten years of operations data for each project.[3] In the Commission's September 28, 2021 response, this item was not addressed or discussed.[4] Operations data is needed in order to understand how each facility is operated and how operations might affect the

[1] As noted in the PAD, some project turbines are out-of-service. At least for Millinocket Lake Storage Development, the choice to keep the turbine offline is routinely evaluated and the turbine could be brought back online if market conditions, and other factors, make it profitable to do so. However, to properly assess the impacts each development may have on the Service's trust resources, clarity and confirmation about (1) how the Projects are operated; and (2) how the Applicant plans to operate the Projects for the duration of any new license term is needed.
[2] Volume 1 of the PAD presents monthly and annual flow duration curves which show outflows from the Ripogenus and Penobscot Mills Projects and are based on GLHA operations data from 2016 through 2020 for the McKay Station and North Twin Development.
[3] Accession No. 20210914-5124
[4] Accession No. 20210928-3057

hydrology in the West Branch and mainstem Penobscot River.[5] This data will also better inform the agencies understanding of study results collected as part of this licensing proceeding.

Therefore, the Service requests the Applicant provide water surface elevation and project discharge (along with other relevant operational data and hydrologic records) at each of the six dams. Ideally hydrologic records maintained by GLHA, and the previous licensee, from 1980 to 2021 would be provided to the agencies. Additionally, the Applicant should deploy water level loggers throughout the system as a means of collecting data on how water surface elevation changes hourly over the course of three years as requested in the *Impacts of Water Level Fluctuations on Riparian and Aquatic Vegetation, Including Invasive Species, Associated Wildlife, and their Associated Habitats* study provided herein.

**5.3 Water Resources**

River Flows

According to the PAD, the North Twin Development dam and the Ripogenus Project (McKay Station) operate in a peaking mode as part of the existing store-and-release license condition(s). While the Millinocket, Dolby, and East Millinocket Development dams are said to be run-of-river facilities in the PAD, they are operated in response to peaking inflows from the North Twin Project. Therefore, outflows of the run-of-river dams also fluctuate similarly to the peaking facilities.

In addition to understanding how the Projects currently operate, a tool (or model) is needed that will allow stakeholders to predict impacts of alternative project operations and any potential mitigation measures to protect or enhance aquatic fish and wildlife resources. Therefore, the Service is requesting a three-dimensional computational fluid dynamics study, provided herein. The CFD study will also allow the agencies to evaluate fish behavior and passage data collected as part of the requested upstream and downstream eel studies (see below) and could be used to help model, and plan for, potential drought and/or flood scenarios that might occur during the duration of any newly issued license due to climate change and other factors.

**5.4 Fish and Aquatic Resources**

Fisheries Management

Currently, there are no upstream or downstream American eel (*Anguilla rostrata*) passage and protection measures installed at the Ripogenus, North Twin, Millinocket, Dolby, East

[5] GLHA states, in Section 1.6 of the PAD, that the impoundments and project operations are used to modify flows in the mainstem Penobscot River. Specifically, "The Project storage impoundments are managed on an annual cycle to dampen the variability and occasional extremes of seasonal precipitation and runoff through storage within the impoundments. This storage allows for continuous flows to downstream aquatic habitat and spawning areas within the West Branch and the mainstem of the Penobscot River during times of lower inflows to the system. In addition, the storage allows flows from the West Branch to be reduced during higher seasonal flow periods when the combined flows from the East and West Branches have the potential to adversely impact human life, property, and environmental resources downstream along the mainstem Penobscot River."

Millinocket, or Millinocket Lake Storage dams. However, as indicated in the PAD, "American eel have been found in each of the Project impoundments."

To date, studies have not been performed to identify information relative to areas where eels concentrate below each dam, where permanent passage facilities would be best placed, nor has there been an assessment of the numbers and size of eels attempting to pass each facility. To fill these data gaps, the Service requests GLHA conduct a study that assesses areas of eel concentration so that permanent upstream passage facilities can be properly sited. Similarly, studies have not been performed to evaluate the route of passage and survival of adult silver phase eels at Ripogenus, North Twin, Millinocket, Dolby, East Millinocket, or Millinocket Lake Storage dams. However, trashrack spacing greater than ¾-inch is known to create a high risk of entrainment and mortality to both migratory and resident fish species (USFWS 2019). To fully understand how adult silver phase eels move past each dam, through the turbine intakes, over spill, and any other routes applicable to each dam, the Service recommends GLHA conduct a downstream eel passage assessment. Turbine injury and mortality studies are also needed and should be used in conjunction with results of the passage routing studies, where applicable, to calculate total through-project survival rates. As part of this assessment, GLHA should perform a downstream eel passage alternatives study, in coordination and via a collaborative process with, the Service (and the other agencies) in order to determine conceptual options, and expected performances for, improved downstream passage that will reduce delay, increase passage efficiency, and increase survival for downstream migrating adult eels in the West Branch. Additionally, data regarding the size range of eels moving past each dam, as well as their migration timing, is needed and should be combined with the other downstream eel studies to better understand survival estimates and to inform when downstream passage and protection measures need to be operated.

The Service herein provides study requests to address these information needs.

Freshwater Mussels

The PAD provides limited information on the distribution and abundance of freshwater mussels within the West Branch of the Penobscot River/within the vicinity of the Ripogenus and Penobscot Mills projects.[6] Given this, the Service is requesting that GLHA conduct a mussel survey (1) in each project impoundment and bypass reach; and (2) in project-affect reaches downstream from project dams and powerhouses (e.g., Upper Gorge, Holbrook Side Channel, what GLHA is referring to as the "Back Channel", Millinocket Stream, etc.) to determine the species composition, distributions, and abundance of freshwater mussels, including the State-listed brook floater (*Alasmidonta varicosa*), yellow lampmussel (*Lampsilis cariosa*), and tidewater mucket (*Leptodea ochracea*).[7]

Should any federally listed, or priority at-risk species, be found at the East Millinocket Development, Dolby Development, Millinocket Development, North Twin Development, Millinocket Lake Storage Development, or Ripogenus the Service reserves the right to request an

[6] A freshwater mussel survey was last performed in parts of the West Branch by IFW in 2009.
[7] The brook floater is also a priority at-risk species for the Service.

instream flow study to assess the impacts of the range of the proposed project discharges on the wetted areas, and optimal habitats, for said species.

**5.6 Wetland, Riparian, and Littoral Vegetation**

Appendix F of the PAD lists the plant species that existed at Ripogenus and Penobscot Mills in the early 1990's, information that was collected during the last relicensing. However, there is no information in the PAD pertaining to how botanical resources may have changed over time due to operation of the Projects. Further, while Table 5.5-5 and 5.5-6 provides a list of invasive plants found within the state of Maine, none are explicitly identified as occurring within the Ripogenus and Penobscot Mills project areas. Likewise, the lists of mammals, birds, amphibians, and reptiles are only those that may occur at each development associated with each of the six developments.

These information gaps need to be filled so that the resource agencies can assess any potential impacts related to operations of the Projects and to develop adequate protection measures to meet management goals and objectives. Plants and wildlife occurring in habitats in the project areas may benefit from PME measures, given the potential effects of current and future operations as well as any potential maintenance activities. Therefore, the Service herein submits a request for such a study as well as an assessment of the impacts of project-induced water level fluctuations on wetlands, littoral and riparian vegetation, and wildlife.

**5.7 Rare, Threated, and Endangered Wildlife Species**

Mist-netting surveys conducted in several locations in Piscataquis County in 2006 and 2008 found northern long-eared bat (NLEB), indicating that the species could be present within the Ripogenus and Penobscot Mills project boundaries. However, baseline information regarding the presence/absence and distribution of the NLEB within the Project's boundaries is lacking. These data are needed to meet the goal of evaluating project effects. An acoustic survey may also provide information regarding the presence of the little brown bat (*Myotis lucifugus*) and tri-colored bat (*Perimyotis subflavus*) within the project areas.[8] The Service herein provides a study request to address these information needs.

*RECOMMENDED STUDIES*

GLHA is not proposing to undertake any studies as part of this relicense proceeding. Enclosed please find our formal study requests (Attachment A) in the format required pursuant to 18 CFR §4.38(b)(5).

*SCOPING DOCUMENT 1*

**3.1.3 Project Operations**

While the Scoping Document and PAD indicate the Millinocket, Dolby, and East Millinocket Development dams are run-of-river facilities, these dams are operating in response to peaking

[8] Both species are currently undergoing consideration for listing by the Service under the Endangered Species Act.

inflows from the North Twin Development dam and Ripogenus (McKay Station). Therefore, the outflows of the Millinocket, Dolby, and East Millinocket Development likely fluctuates, like that of the peaking facilities upstream. Operations data is needed in order to understand if Millinocket, Dolby, and East Millinocket are truly operated in a run-of-river mode.

### 4.1.2 Water and Aquatic Resources

Effects of project facilities and operations on water and aquatic resources, including fish migration, and wildlife and botanical resources should be analyzed for each individual dam, as well as cumulatively (to include the mainstem Penobscot River). Additionally, effects of fish entrainment should not be limited to fish populations but should include impacts to food web interactions and overall ecosystem productivity.

Thank you for this opportunity to comment. Please direct any questions to Julianne Rosset at julianne_rosset@fws.gov.

# ATTACHMENT A

## Study Requests

# Impacts of Water Level Fluctuations on Riparian and Aquatic Vegetation, Including Invasive Species, Associated Wildlife, and their Habitats in the Ripogenus and Penobscot Mills Impoundments

(Ripogenus, P-2572; and Penobscot Mills, P-2458)

***Goals and Objectives***

The goal of this study is to obtain baseline information on riparian, wetland, emergent and submerged aquatic vegetation, and associated shallow water aquatic habitats (subject to operational inundation and exposure to near exposure) known to occur in the project areas. Information would be used to determine whether riparian, wetland, emergent aquatic vegetation (EAV) and submerged aquatic vegetation (SAV), littoral, and shallow water (e.g., mid-river bars and shoals) habitats are impacted by current water level fluctuations permitted under East Millinocket Development, Dolby Development, Millinocket Development, North Twin Development, Millinocket Lake Storage Development, and the Ripogenus projects' licenses and whether these vegetation types and shallow water habitats can be protected and restored by modifications to project operations or other mitigation measures. This analysis needs to take into account existing and potential future limits on impoundment level fluctuations intended to limit recreation impacts, and the interactions of any changes in impoundment level fluctuation range or frequency and discharge changes under any new license issued for the projects. This information is needed to determine whether existing operations affect plants, habitat, and wildlife in the project areas, whether aquatic vegetation and its habitats can be enhanced by modifications to project operations, or other mitigative measures, and whether there is any unique or important shoreline or aquatic habitats that should be protected.

The specific objectives of the field study, at a minimum, include:

1. collect data on how water surface elevation changes hourly over the course of three years;
2. quantitatively describe and map wetland types within 250 feet of the shoreline, and describe associated wildlife;
3. delineate, quantitatively describe, and map all wetland types, including invasive species and wildlife observed (e.g., bald eagle nesting, waterfowl nesting, etc.) within 200 feet of the shoreline, and the extent of this habitat if it extends beyond 200 feet; and
4. quantitatively describe (e.g., substrate composition, vegetation type and abundance) and map shallow water aquatic habitat types subject to project operation inundation and exposure, noting and describing additional areas where water depths at the lowest operational range(s) are wetted to a depth less than one foot (flats, near shore areas, gravel bars, with very slight bathymetric change).

A second year of study may be required should river discharge in the first year prove to be atypical (outside of 25-75th percentile of average weekly flow values) during the study period.

The field study should produce a habitat inventory report that includes:

1. the results of the field study in the form of maps and descriptions;
2. an assessment of project effects on wetland, riparian, littoral zone vegetation and shallow water habitats, invasive plant species, and wildlife habitat at the project;
3. recommendations for any necessary plant, habitat type, or wildlife, protection and/or invasive species control measures; and
4. recommendations for plant, habitat type, or wildlife protection and/or invasive species control measures, including riparian buffer restoration and protection and protection of key nest and roost trees for bald eagles.

***Resource Management Goals***

The U.S. Fish and Wildlife Service (Service) seeks the accomplishment of a number of resource goals and objectives through the relicensing process for the projects. General goals include the following:

1. Ensure that protection, mitigation and enhancement measures are commensurate with project effects and help meet regional fish and wildlife objectives for the basin.
2. Conserve, protect, and enhance the habitats for fish, wildlife, and plants that continue to be affected by the projects.

Specific to aquatic resources, the Service's goals are:

1. Protect, enhance, or restore diverse high-quality aquatic and riparian habitats for plants, animals, food webs, and communities in the watershed and mitigate for loss or degradation of these habitats.
2. Minimize current and potential negative project operation effects on water quality and aquatic habitat.

***Public Interest***

The requester is a natural resource agency.

***Existing Information and the Need for Additional Information***

Existing information in the Pre-Application Document (PAD) does not quantify EAV and SAV in the project area associated with each development, nor does it quantify shallow aquatic habitat types and physical features (e.g., depths, substrates, wood structure), that are the associated environment for aquatic biota in the project area(s) associated with each development. The PAD does indicate that there is aquatic vegetation present at certain developments but does not provide monitoring data.

Further, the PAD indicates that several developments associated with the Penobscot Mills project (North Twin Development) and Ripogenus (McKay Station) operate in a peaking mode as part of their store-and-release license conditions. The Millinocket, Dolby, and East Millinocket

Developments, although being run-of-river facilities, presumably operate in response to peaking inflows from the North Twin Project; thus, outflows of these dams also fluctuate similarly to peaking facilities.

It is unclear what the actual timing, frequency and magnitude of operations are over the course of a year, at each development, and how that relates to aquatic plant species establishment, growth, survival, littoral zone or other shallow water habitats. It's also unclear how operations affect fish spawning periods like reproduction success and subsequent recruitment (e.g., bass and fall fish nests) in available and utilized habitat, and how the quantity and quality of these shallow water habitats are affected by project operational manipulation/alteration (as currently permitted or proposed).

The PAD provides a list of plant and wildlife species whose native ranges overlap with the project areas, but it does not provide any baseline information on known occurrences of these species in the wetlands, riparian, littoral, or shallow water habitats, within or adjacent to the project area. Plant and wildlife occurring in these habitats may benefit from protection, mitigation, and enhancement (PMEs) measures, given the potential effects of continuing the current peaking operating regime.

***Nexus to Project Operations and Effects***

Water level fluctuations due to project operations could affect EAV and SAV habitat as well as the quantity and quality of littoral and shallow water habitat. These operational water level fluctuation effects are expected to impact fish species use of these habitats and may affect spawning fishes, reproductive success, and subsequent population recruitment including but not limited to sea lamprey, fallfish, and bluegill, which spawn in mid-to-late spring through early summer in areas subject to daily or more frequent water level fluctuations.

The current operating mode as the agencies understand it, as well as the unknowns, may affect wetland riparian, littoral and other shallow water habitats, and promote the introduction and expansion of invasive plant species through fluctuating water levels. A study that explains the relationship between the proposed mode of operation and the type and quantity of wetland, riparian, littoral, shallow water habitats, and invasive species affected would help inform a decision on the need for protection and/or control of these resources in any new license.

Riparian buffers provide for riverbank stability, reduction in nutrient and sediment from runoff, shading and reduced solar heating of river waters and wildlife habitat (including eagle nesting and roosting habitat) and movement corridors. Management of the project's shorelines are within the scope of project review and a Shoreline Management Plan is likely to be required. Incorporation of riparian resource protection and enhancement into this plan will require baseline information on existing conditions

***Methodology Consistent with Accepted Practice***

The Applicant should deploy water level loggers throughout the West Branch of the Penobscot River as a means of collecting data on how water surface elevation changes hourly over the

course of two to three years. This data will better inform the information below, as well as data collected in other studies related to this relicensing.

The proposed study should utilize existing information (any existing maps portraying wetland types, detailed bathymetry data, etc.) in conjunction with field surveys designed to describe the characteristics of each mapped wetland, riparian, littoral and shallow water habitat, including plant species composition, relative abundance/density, habitat quality, and land use. Surveys should be conducted to describe these habitats at the lowest water level operational range permitted on a daily operation schedule, under low flow conditions. Information collected should include:

1. plant species composition, and their relative abundance/density and condition/structure (e.g., seedlings);
2. structured data, including estimates of average heights and aerial cover of each vegetation layer (specifically denoting invasive species);
3. aquatic habitat substrate composition, quantity (i.e., percent types and area), wood structure (relative abundance measure applied by area), water depths (inundated, exposed, and water less than one foot);
4. predominate land use(s) associated with each cover type;
5. wildlife sightings should be noted; and
6. field-verified wetland, riparian, and littoral and shallow water habitats and invasive species occurrences should be geo-referenced as polygons and overlain on orthophoto at a suitable scale.

***Level of Effort/Cost, and Why Alternative Studies Will Not Suffice***

A wetland, riparian, littoral/shallow water, invasive species inventory, coupled with the species studies component outlined above, of the scope envisioned would likely require six to eight months to complete and cost $40,000 to $50,000. No alternatives are proposed.

# Three-Dimensional Computational Fluid Dynamics (CFD) Modeling Upstream and Downstream of the Discharge and in the Vicinity of Powerhouse Forebays

(Ripogenus, P-2572 and Penobscot Mills, P-2458)

***Goals and Objectives***

The goal of this study is to determine the potential impacts of the East Millinocket Development, Dolby Development, Millinocket Development, North Twin Development, Millinocket Lake Storage Development, and the Ripogenus dams on: (1) the zone of passage for migratory fish near turbine discharge; and (2) natural flow regimes in the West Branch of the Penobscot River immediately upstream and downstream of each project.

Specific objectives of the study include:

1. Develop a CFD model of the full width of the West Branch upstream and downstream of each projects discharge.

2. Model flow characteristics upstream and downstream of the project under existing project operations and at several representative river flow levels, as well as any other modifications under consideration (including potential future impacts to operations as a result of climate change), to assess potential impacts to fish and wildlife resources.

3. Assess velocities and flow fields at, and in proximity to each project's intake/discharge structure when generating, and their potential to (1) interfere with fish migration; (2) create undesirable attraction flows; and (3) result in fish entrainment and/or impingement.

4. Assess the potential for velocity barriers to aquatic organism movement in the mainstem river resulting from generation flows at each project, alone and in combination with generation flows from the other projects on the West Branch.

5. Model, and then evaluate, flow characteristics under alternative project operations with potential measures to avoid, minimize, or mitigate impacts to fish and wildlife resources.

6. Define flow velocities, fields/magnitudes, and direction in front of each project's powerhouse.

This information is necessary to properly assess the scale, and feasibility, of potential upstream and downstream passage alternatives (see the *Downstream Passage Alternatives* study request). The requested information can be utilized to create a more productive, cost-effective, and

efficient alternatives analysis process by helping to narrow the focus to a minimal number of feasible alternatives.

***Resource Management Goals***

The mission of the U.S. Fish and Wildlife Service (Service) is to work with others to protect, conserve and enhance fish, wildlife, plants, and their habitats for the continuing benefit of the American people. Service trust resources include wetlands, endangered species, and migratory species, all of which occur (or have the potential to occur) in the project area. Instream flow is an important riverine habitat characteristic that can have a large impact on aquatic habitat for fish, wildlife, and plants. Flow is an important directional guidance cue for instream navigation and attraction to upstream, and downstream, fishway entrances for migratory fish. As for downstream migration of adult eel, the results from the models will reveal flow magnitude and direction in front of each powerhouse.

These study requests are intended to facilitate the collection of information necessary to conduct effects analyses and to develop reasonable and prudent conservation measures, and protection, mitigation, and enhancement measures pursuant to the Fish and Wildlife Coordination Act, as amended (16 U.S.C. §661, *et seq*.), and the Federal Power Act (16 U.S.C. §791a, *et seq*.).

***Public Interest***

The requestor is a natural resource agency.

***Existing Information and the Need for Additional Information***

No project-specific information exists that will allow for a comprehensive assessment of existing project operations on West Branch flows and on fish and aquatic organisms in the project areas upstream and downstream of each dam. The Pre-Application Document does not contain any information, or tool(s), that will allow for predictions of impacts of alternative project operations, or potential mitigation measures to protect or enhance aquatic fish and wildlife resources. Further, a comprehensive understanding of fish behavior at each powerhouse forebay is needed to create safe, timely, and effective upstream and downstream passage for American eel on the West Branch. CFD models are a relatively cost-effective way to analyze existing and future conditions. As such, changes in the amount of attraction water, changes in which turbines are operating, and which spillway gates are releasing water can all be examined.

The Service notes, modeling this information now can help the resource agencies, as well as the Applicant, account for potential drought and/or flood related scenarios that might occur during the duration of any newly issued license, due to climate change and other factors.

***Nexus to Project Operations and Effects***

The Ripogenus and Penobscot Mills Projects have direct impacts to instream flows, aquatic habitats, and upstream and downstream migrating American eel in the West Branch of the Penobscot River. The development of the requested CFD models will aid in determining the potential impacts of the East Millinocket Development, Dolby Development, Millinocket

Development, North Twin Development, Millinocket Lake Storage Development, and Ripogenus dam. For downstream passage, the Service has velocity vector guidelines associated with intake racks and guidance screens; the output from these models will inform the resource agencies under what conditions appropriate velocities are being met and when they are being exceeded. Additionally, modeling of flow will aide in our interpretation of year one downstream passage telemetry results. Therefore, aspects of the CFD modeling effort could focus on the locations identified as important in the study results and GLHA could assess changes to structures of operations and evaluate them in the model. Suitable alternatives would then be tested in year three studies.

***Methodology Consistent with Accepted Practice***

A three-dimensional CFD model has become an increasingly common standard of analysis at hydroelectric projects across the nation. Within the northeast region, we have seen these types of models developed at the Holyoke (P-2004), Brunswick (P-2284), Shawmut (P-2322), Milford (P-2534) and Lowell (P-2790) projects. We would expect to engage with the licensee in terms of determining the appropriate areas and flows to be modeled. We expect the spatial extent of the model at each study site will vary. Given the large number of ways in which output from these models can be presented and the near infinite number of flows which could potentially be modeled, we would expect to consult with the applicant to reach agreed upon modeling efforts and scenarios to be examined.

***Level of Effort/Cost, and Why Alternative Studies Will Not Suffice***

The cost of developing, running, and testing a CFD model can vary tremendously; one large variable in determining the cost is based on the amount of existing bathymetric data to which GLHA currently has access. We roughly estimate the maximum cost of each CFD model to be $50,000, assuming no bathymetric data currently exists. Proactive communication with resource agencies will reduce the cost and iterative effort. Given the level of effort that has occurred at other projects where licensees have proposed to amend their license, we see the level of effort requested here as reasonable, given that GLHA is seeking a renewal of its license.

Regarding alternatives, no project-specific instream flow analysis tool has been developed for the West Branch that will allow for assessment of existing operations and alternative operational impacts on instream flow and aquatic habitat for fish and wildlife resources. Further, the model, once built, can be used to simulate flow conditions in the vicinity of each project during the migratory fish passage season and can be used together with behavior studies (i.e., telemetry studies and entrainment studies requested herein) to assess the impacts of varying project operations or potential mitigation operations and measures on fish migration and aquatic habitat. The Service knows of no other tool that will provide for these types of assessments. No alternatives are proposed.

# Upstream American Eel Passage Assessment
(Ripogenus, P-2572 and Penobscot Mills, P-2458)

The PAD identifies American eel as present in the Project area. Dams, such as East Millinocket Development, Dolby Development, Millinocket Development, North Twin Development, Millinocket Lake Storage Development, and the Ripogenus dam, are known to impair migration success for catadromous species such as American eel (ASMFC 2014). Presently, upstream passage facilities specific to the needs of migrating juvenile eels are not available at either project (or any of the dams that comprise the two projects). Installing upstream eel passage at each facility will address direct project related impacts and facilitate restoration of American eel within the Penobscot River watershed. The study request below is intended to provide data necessary to develop reasonable and prudent conservation measures, specifically safe, timely and effective passage for American eel.

If aspects of the project design or project operations changes with any new license, this study may need to be repeated.

***Goals and Objectives***

The goal of this study is to assess the locations for dedicated upstream passage for American eel.

The study has two objectives:

1. Conduct systematic surveys of eel presence/abundance below the East Millinocket Development, Dolby Development, Millinocket Development, North Twin Development, Millinocket Lake Storage Development, and the Ripogenus dam to identify areas of concentration of eels staging in pools or attempting to ascend wetted structures that would potentially establish the most effective location to place upstream eel passage facilities.
2. Collect eels with temporary trap/pass devices at areas identified from surveys as potential location of eel concentrations to assess whether eels can be collected/passed in substantial numbers, and whether locations are viable sites for permanent eel trap/pass structures.

***Resource Management Goals***

The Atlantic States Marine Fisheries Commission (ASMFC) has developed three documents related to the management of American eel and hydropower facilities:

1. Interstate Fishery Management Plan for American Eel. April 2000. Atlantic States Marine Fisheries Commission.
2. Addendum II to the Fishery Management Plan for American Eel. Atlantic States Marine Fisheries Commission. Approved October 23, 2008. 8 pp.
3. Addendum III to the Fishery Management Plan for American Eel. Atlantic States Marine Fisheries Commission. Approved August 2014. 19 pp.

Objectives of the management plan include: (1) protect and enhance American eel abundance in all watersheds where eel now occur; and (2) where practical, restore American eel to those waters where they had historical abundance, but may now be absent, by providing access to inland waters for glass eel, elvers, and yellow eel, and adequate escapement to the ocean for pre-spawning adult eel.

Addendum II contains specific recommendations for improving upstream and downstream passage of American eel, including requesting that member states and jurisdictions seek special consideration for American eel in the Commission's relicensing process.

Based on these plans, the U.S. Fish and Wildlife Service (Service) seeks the accomplishment of a number of resource goals and objectives through the relicensing process for the project. General goals include the following:

1. Ensure that protection, mitigation and enhancement measures are commensurate with project effects and help meet regional fish and wildlife objectives for the basin.
2. Conserve, protect, and enhance the habitats for fish, wildlife, and plants that continue to be affected by the project.

Specific to upstream passage of American eel, the Service's goals are:

1. Minimize current and potential negative project operational effects that could hinder management goals and objectives.
2. Minimize project-related sources of upstream passage delay, injury, and stress in order to facilitate access to historical rearing habitat.

Our study requests are intended to facilitate the collection of information necessary to conduct effects analyses and to develop reasonable and prudent conservation measures, and protection, mitigation, and enhancement measures pursuant to the Endangered Species Act of 1973, as amended (16 U.S.C. §1531 *et seq*.), the Fish and Wildlife Coordination Act, as amended (16 U.S.C. §661 *et seq*.), and the Federal Power Act (16 U.S.C. §791a, *et seq*.).

***Public Interest***

The requester is a natural resource agency.

***Existing Information and the Need for Additional Information***

The PAD does not provide information relative to areas eels concentrate below the East Millinocket Development, Dolby Development, Millinocket Development, North Twin Development, Millinocket Lake Storage Development, or Ripogenus dams or an assessment of the numbers and size of eels attempting to ascend each facility. Data from this study will provide information in support of the licensing process and in developing the administrative record for potential mitigation measures under Section 18 and/or Section 10(j) of the Federal Power Act.

***Nexus to Project Operations and Effects***

Dams impede the safe, timely, and effective passage of eels. The ability of eels to pass a dam depends on factors such as its height, hydraulics, presence of climbable surfaces (e.g., rough surface, wetted substrate), presence of predators, and risk of exposure to heat or drying while climbing a dam among others (Solomon and Beach 2004). Passage is also limited by the size of eel present. Only small juvenile eels are able to scale vertical surfaces (Machut et al. 2007). The design of the East Millinocket Development, Dolby Development, Millinocket Development, North Twin Development, Millinocket Lake Storage Development, and the Ripogenus dam creates multiple potential sites for upstream migrating eels to congregate. Site-specific data are necessary to understand project effects and support the decision process for properly designing and siting eel passage facilities.

***Methodology Consistent with Accepted Practice***

This study request consists of two parts: (a) an initial survey for presence and identification of areas where juvenile eels congregate and (b) a site evaluation for permanent eel passage. The methodologies described here are consistent with commonly accepted practices.

1. Objective 1: Systematic Surveys

   Surveys of eel presence and relative abundance should be conducted at regular intervals (as described below) throughout the eel upstream migratory season (approximately April 1 to November 30). Surveys should consist of visual inspection and trapping in likely areas where eels may concentrate. Areas of quiescent water and leakage points along the downstream face of the dams should be targeted. Methods should include visual surveys (on foot, from a boat, or snorkeling) and trapping using small mesh (< 1/8" clear opening) baited eel pots. Visual surveys should be performed once per week, at night, preferentially during precipitation events. Trap sets should be performed once per week, with an overnight soak time. Recorded data should include location, observation of eels (presence, absence, relative numbers, relative sizes, behaviors, time/date of observation), and survey method.

2. Objective 2: Trap/Pass Collections

   Areas identified from the systematic surveys as having significant number of eels present should be targeted as potential areas for permanent eel trap/passes and should be initially

assessed using temporary/portable trap passes. Temporary trap/passes should be purpose-designed and built for each location and operated throughout the eel upstream migratory season in the year following the survey. Ramp-type traps with supplementary attraction flow are preferred temporary trap/pass designs (Solomon and Beach 2004). Traps should operate daily, with catches quantified every 2-3 days. Data recorded should include location, trapping interval, absolute numbers of eels trapped, relative eel sizes, and hydraulic and environmental conditions during the trapping period.

All collected eels from surveys should be released at their point of capture; those eels collected from trap/pass collections should be transported to and released above each respective dam.

### *Level of Effort/Cost, and Why Alternative Studies Will Not Suffice*

The level of cost and effort for the survey component of the study would be low; a minimal number of personnel may be able to conduct the weekly surveys. The trap/pass component would require low to moderate cost and effort. We estimate the cost will be approximately $50,000 for the study. No alternatives are proposed.

# Downstream American Eel Passage Assessment
(Ripogenus, P-2572 and Penobscot Mills, P-2458)

***Goals and Objectives***

The goal of this study is to determine the impact of the East Millinocket Development, Dolby Development, Millinocket Development, North Twin Development, Millinocket Lake Storage Development, and the Ripogenus hydroelectric projects on the outmigration of silver eels in the West Branch of the Penobscot River. Project operations can result in delay, mortality or injury during emigration. It is important to understand the passage routes at the project and the potential for delay, injury, and mortality to determine measures and recommendations to increase survival and improve fish passage at the projects.

The objectives of this study are:

1. Quantify the movement rates, including delays, and relative proportion of eels passing via various routes at the project (i.e., through the turbines, through the downstream bypass, via spill at the dams, etc.).
2. Quantify the relative proportion of eels passing each potential emigration route (spill, bypass pipes, powerhouse) at the project during various project operations.
3. Evaluate instantaneous and latent mortality and injury of eels passed via each potential route.

***Resource Management Goals***

The Atlantic States Marine Fisheries Commission (ASMFC) has developed three documents related to the management of American eel and hydropower facilities:

4. Interstate Fishery Management Plan for American Eel. April 2000. Atlantic States Marine Fisheries Commission.
5. Addendum II to the Fishery Management Plan for American Eel. Atlantic States Marine Fisheries Commission. Approved October 23, 2008. 8 pp.
6. Addendum III to the Fishery Management Plan for American Eel. Atlantic States Marine Fisheries Commission. Approved August 2014. 19 pp.

Objectives of the management plan include: (1) protect and enhance American eel abundance in all watersheds where eel now occur; and (2) where practical, restore American eel to those waters where they had historical abundance, but may now be absent, by providing access to inland waters for glass eel, elvers, and yellow eel, and adequate escapement to the ocean for pre-spawning adult eel.

Addendum II contains specific recommendations for improving upstream and downstream passage of American eel, including requesting that member states and jurisdictions seek special consideration for American eel in the Commission's relicensing process.

The U.S. Fish and Wildlife Service (Service) seeks the accomplishment of a number of resource goals and objectives through the relicensing process for the project. General goals include the following:

1. Ensure that protection, mitigation and enhancement measures are commensurate with project effects and help meet regional fish and wildlife objectives for the basin.
2. Conserve, protect, and enhance the habitats for fish, wildlife, and plants that continue to be affected by the project.

Specific to downstream passage of American eel, the Service's goals are:

1. Minimize current and potential negative project operation effects that could hinder management goals and objectives.
2. Minimize project-related sources of downstream passage delay, injury, stress, and mortality in order to maximize the number of silver eels migrating to the spawning grounds.

These study requests are intended to facilitate the collection of information necessary to conduct effects analyses and to develop reasonable and prudent conservation measures, and protection, mitigation, and enhancement measures pursuant to the Fish and Wildlife Coordination Act, as amended (16 U.S.C. §661, *et seq*.), and the Federal Power Act (16 U.S.C. §791a, *et seq*.).

***Public Interest***

The requester is a natural resource agency.

***Existing Information and the Need for Additional Information***

The Pre-Application Document does not contain information on the route of passage or the amount of delay that occurs for emigrating adult eels.

To date, no directed studies of eel entrainment or mortality have been conducted at the projects. These information gaps need to be filled so the natural resource agencies can assess the relative and cumulative impacts of project operations on outmigrating eels and develop adequate passage and protection measures to meet management goals and objectives.

***Nexus to Project Operations and Effects***

The East Millinocket Development, Dolby Development, Millinocket Development, North Twin Development, Millinocket Lake Storage Development, and the Ripogenus hydroelectric projects do not have entrainment prevention measures in place at their respective turbine intakes, nor are there designated spillway passage routes or fish bypass systems. To determine overall project survival, we need to understand the routes of emigration, the potential for delay under different river flow conditions and project operations, and the level of injury and/or mortality resulting from each potential passage route (i.e., the turbines, the spillway, etc). This study will contribute

information in support of the licensing process, and development the administrative record in support of potential mitigation measures under Section 18 and/or 10(j) of the Federal Power Act.

***Methodology Consistent with Accepted Practice***

In order to understand the movements of outmigrating silver eels as they relate to operations at Ripogenus and Penobscot Mills, radio telemetry technology should be utilized. Radio- and PIT-tagging is an accepted technology which has been used for a number of studies associated with hydropower projects, including at projects in the mainstem Penobscot River and the Merrimack River.

Studies should be designed to investigate the size class among the full spectrum of silver eels at each project, route selection (i.e., entrainment vs. spill) independently from estimation of mortality/injury, because these metrics require different methodologies. Studies will also likely benefit from data collected over two study years to account for differences in environmental conditions and natural variation in eel migration (especially route selection studies, which may be more significantly affected by environmental conditions during a given season than mortality/injury studies). It is also envisioned that results from route selection studies can guide design of turbine mortality studies. Therefore, it is proposed, at a minimum, route selection studies be conducted in multiple years, but mortality/injury studies may be conducted after the first year of route selection studies have been completed.

**Objective 1: Route Selection**

This study will involve systematic releases of radio- and PIT-tagged silver phase eels at strategic points above areas of interest, to assess general routes of passage (i.e., via spill, bypass, or turbines). Active downstream migrants should be collected within-basin if possible, but fish sourced from out-of-basin may be acceptable to meet sample size demands. Experimental fish must meet morphometric (e.g., eye diameter relative to body size) criteria to ensure they are migrant silver phase. Collections should be made within the migratory season, and eels should be tagged and released within 21 days after capture, but preferably within 7 days (particularly if the test eels are from out-of-basin).

All telemetered eels will be radio- and PIT-tagged. PIT antennas will be installed and monitored continuously to verify passage of eels via bypass channels.

A minimum number of 150 telemetered eels (e.g., five separate groups of approximately 30 eels each) per development will be required to maximize the data return. If enough eels cannot be captured for this study in a single year, the study will need to take place over the course of two years. Tagged eels should be released at an appropriate distance upstream of each dam. Groups of eels should be released during spill (if any) and non-spill and during periods of low, moderate, and high generation conditions. Since fish can drift a considerable distance downstream after they have died (Havn et al. 2017), a minimum of 25 dead eels should also be released as a control group in this study (at each project). Additionally, a control is needed to allow comparisons of movement rate and

success of passed and non-passed eels in reaching the detection point downstream. Therefore, an additional 50 telemetered (uninjured) eels should be released below each project and tracked as they emigrate.

Telemetry receivers and antennas should be located upstream and downstream of the spillway, at turbine intakes, station tailraces, etc. These locations will permit assessment of passage via the following potential routes: spillway; station turbines; any existing upstream fishway attraction water intake, etc. The final placement of receivers and antennas should be developed in consultation with the Service and the other agencies.

Mobile tracking (i.e., via boat) in the river between release sites and tens of kilometers downstream will be performed at regular intervals during and after releases to confirm routes and fates of passed fish or lost fish.

Movement rates (time between release and detection at radio antenna locations, and between radio antenna locations) of eels passing the projects by various routes will also be quantified.

The route selection portion of this study should occur in both study years.

**Objective 2: Spill, Bypass, and Turbine Mortality/Injury Studies**

Spill, bypass, and turbine mortality will be assessed using a balloon-tag method.

For spill mortality sites (dam spillways and downstream bypasses), tagged eels will be injected or released into spill flow at points where water velocity exceeds 10 ft/sec to minimize the possibility of eels swimming upstream into the headpond or canal. Passed balloon-tagged eels will be recovered below areas of spill and held for 96 hours in isolated tanks for observation of injury and latent mortality; unrecovered balloon-tagged eels will be censored from the data. Passed eels should be x-rayed for any potential injuries per Muller et al. 2020.

For turbine mortality sites, tagged eels will be injected into intakes of all units associated with the projects, operating at a full range of settings where intake water velocity exceeds 10 ft/sec to minimize the possibility of eels swimming back upstream through the intakes. Passed balloon-tagged eels will be recovered in the tailrace(s) and held for 48 hours in isolated tanks for observation of injury and latent mortality; unrecovered balloon-tagged eels will be censored from the data.

If the balloon-tag mortality component of the study occurs in study year one, all possible route selection sites would need to be evaluated. If the balloon-tag mortality component of the study occurs in study year two, results from the route selection study could be used to inform which sites need to be evaluated for mortality. Eels recovered from balloon-tag studies should not be used for route selection studies.

Data analyses of route selection and mortality (instantaneous and latent) will follow standard methodology.

Project operation (flows, levels, gate openings, number of units operating and operation level) and environmental conditions (river flow, temperature, turbidity, air temperature, precipitation) will be monitored regularly (hourly measurements if possible) throughout the duration of the studies and assessed for potential relationships to passage route selection, migratory delay, and/or passage survival.

These methodologies are consistent with accepted practice.

***Level of Effort/Cost, and Why Alternative Studies Will Not Suffice***

The level of cost and effort for the downstream eel passage study will be moderate to high; silver eels would need to be collected, tagged, and released in several locations over the course of the migration season. Data would need to be retrieved periodically, then analyzed. A multi-site route selection study conducted by the USGS Conte Lab on the Shetucket River in Connecticut cost approximately $75,000 for the first year of study. Costs are estimated at $100,000 per year for the route selection study and $50,000 to $75,000 for the spill, bypass, canal, and turbine mortality/injury study. No alternatives are proposed.

# Downstream Passage Alternatives Study
(Ripogenus, P-2572; and Penobscot Mills, P-2458)

***Goals and Objectives***

The goal of this study is to determine conceptual options, and expected performances for, improved downstream passage that will reduce delay, increase passage efficiency, and increase survival for downstream migrating adult eels as they attempt to pass the East Millinocket Development, Dolby Development, Millinocket Development, North Twin Development, Millinocket Lake Storage Development, and Ripogenus dam.

***Resource Management Goals***

The Atlantic States Marine Fisheries Commission (ASMFC) has developed three documents related to the management of American eel and hydropower facilities:

7. Interstate Fishery Management Plan for American Eel. April 2000. Atlantic States Marine Fisheries Commission.
8. Addendum II to the Fishery Management Plan for American Eel. Atlantic States Marine Fisheries Commission. Approved October 23, 2008. 8 pp.
9. Addendum III to the Fishery Management Plan for American Eel. Atlantic States Marine Fisheries Commission. Approved August 2014. 19 pp.

Objectives of the management plan include: (1) protect and enhance American eel abundance in all watersheds where eel now occur; and (2) where practical, restore American eel to those waters where they had historical abundance, but may now be absent, by providing access to inland waters for glass eel, elvers, and yellow eel, and adequate escapement to the ocean for pre-spawning adult eel.

Addendum II contains specific recommendations for improving upstream and downstream passage of American eel, including requesting that member states and jurisdictions seek special consideration for American eel in the Commission's relicensing process.

The U.S. Fish and Wildlife Service (Service) seeks the accomplishment of a number of resource goals and objectives through the relicensing process for the project. General goals include the following:

3. Ensure that protection, mitigation and enhancement measures are commensurate with project effects and help meet regional fish and wildlife objectives for the basin.
4. Conserve, protect, and enhance the habitats for fish, wildlife, and plants that continue to be affected by the project.

Specific to downstream passage of American eel, the Service's goals are:

3. Minimize current and potential negative project operation effects that could hinder management goals and objectives.
4. Minimize project-related sources of downstream passage delay, injury, stress, and mortality in order to maximize the number of silver eels migrating to the spawning grounds.

These study requests are intended to facilitate the collection of information necessary to conduct effects analyses and to develop reasonable and prudent conservation measures, and protection, mitigation, and enhancement measures pursuant to the Fish and Wildlife Coordination Act, as amended (16 U.S.C. §661, *et seq*.), and the Federal Power Act (16 U.S.C. §791a, *et seq*.).

***Public Interest***

The requester is a natural resource agency.

***Existing Information and the Need for Additional Information***

As indicated in the Pre-Application Document (PAD), eels occur upstream and downstream of the Ripogenus and Penobscot Mills projects. The American eel is a native migratory fish species of the Penobscot River watershed with a catadromous life cycle. Eels are widely recognized as a species of high ecological value and significance in its native habitats and has a significant commercial value in certain markets. In addition, eels were important historically to the Penobscot Indian Nation and other tribes for spiritual sustenance as well as physical subsistence.

In the PAD GLHA states that downstream passage is not provided at the East Millinocket Development, Dolby Development, Millinocket Development, North Twin Development, Millinocket Lake Storage Development, or Ripogenus dam. Therefore, the current configuration at each facility is not designed to today's fish passage design criteria and is likely insufficient to adequately pass American eel as they attempt to migrate downstream past each project. An alternatives analysis of the existing configuration at each dam and the subsequent impact(s) on adult eels is needed to evaluate each existing project as well as potential future project design and operation(s).

***Nexus to Project Operations and Effects***

Hydropower project related mortality and delay has a direct effect on migratory fish populations. East Millinocket Development, Dolby Development, Millinocket Development, North Twin Development, Millinocket Lake Storage Development, and Ripogenus dam all lack guidance structures to keep fish out of project turbines. Therefore, eels in the West Branch are likely not realizing their full juvenile production and adult escapement potential. Data derived from this study will facilitate evaluation of various fish passage alternatives, inform the Federal Energy Regulatory Commission’s (Commission) licensing process, and contribute to the development of an administrative record in support of protection and enhancement opportunities related to American eel.

***Methodology Consistent with Accepted Practice***

Fish Passage Engineering Alternative studies are a common way to explore various options in the decision-making process and have been used by the Commission in several licensing proceedings.

This study will require a review of existing downstream fish passage technologies that meet Service fish passage criteria (USFWS 2019 or the most recent version, as they become available) and should consist of conceptual engineering designs of downstream fish passage options that include physical screening of fish, adequate flows for attraction, and adequate relative velocities directing fish to downstream passage structures. Expected performance of each alternative should also be included in any report developed for this study.

The alternatives GLHA proposes to study for each project, the depth and breadth of the conceptual design, and the itemization and source of costs (as well as any potential lost generation modeling) should be agreed upon by the Service, and the other agencies, prior to GLHA conducting the study.

***Level of Effort/Cost, and Why Alternative Studies Will Not Suffice***

The level of cost and effort for this study would be low to moderate; we estimate the cost will be approximately $30,000. No alternatives are proposed.

# Evaluation of the Size of American Eels and the Timing of their Downstream Migratory Movements

(Ripogenus, P-2572; and Penobscot Mills, P-2458)

***Goals and Objectives***

The goal of this study is to understand the size range of eels moving past the projects as well as the migration timing of adult, silver-phase American eels in relationship to environmental factors and operations of hydropower projects on West Branch of the Penobscot River.

The objective of this study is to quantify and characterize (1) the full spectrum of silver eel sizes at each project; and (2) the general migratory timing and presence of adult, silver-phase American eels in the West Branch relative to environmental factors and operations of the East Millinocket Development, Dolby Development, Millinocket Development, North Twin Development, Millinocket Lake Storage Development, and Ripogenus hydroelectric projects.

***Resource Management Goals***

The Atlantic States Marine Fisheries Commission (ASMFC) has developed three documents related to the management of American eel and hydropower facilities:

10. Interstate Fishery Management Plan for American Eel. April 2000. Atlantic States Marine Fisheries Commission.
11. Addendum II to the Fishery Management Plan for American Eel. Atlantic States Marine Fisheries Commission. Approved October 23, 2008. 8 pp.
12. Addendum III to the Fishery Management Plan for American Eel. Atlantic States Marine Fisheries Commission. Approved August 2014. 19 pp.

Objectives of the management plan include: (1) protect and enhance American eel abundance in all watersheds where eel now occur; and (2) where practical, restore American eel to those waters where they had historical abundance, but may now be absent, by providing access to inland waters for glass eel, elvers, and yellow eel, and adequate escapement to the ocean for pre-spawning adult eel.

Addendum II contains specific recommendations for improving upstream and downstream passage of American eel, including requesting that member states and jurisdictions seek special consideration for American eel in the Commission's relicensing process.

The U.S. Fish and Wildlife Service (Service) seeks the accomplishment of a number of resource goals and objectives through the relicensing process for the project. General goals include the following:

5. Ensure that protection, mitigation and enhancement measures are commensurate with project effects and help meet regional fish and wildlife objectives for the basin.
6. Conserve, protect, and enhance the habitats for fish, wildlife, and plants that continue to be affected by the project.

Specific to downstream passage of American eel, the Service's goals are:

5. Minimize current and potential negative project operation effects that could hinder management goals and objectives.
6. Minimize project-related sources of downstream passage delay, injury, stress, and mortality in order to maximize the number of silver eels migrating to the spawning grounds.

These study requests are intended to facilitate the collection of information necessary to conduct effects analyses and to develop reasonable and prudent conservation measures, and protection, mitigation, and enhancement measures pursuant to the Fish and Wildlife Coordination Act, as amended (16 U.S.C. §661, *et seq*.), and the Federal Power Act (16 U.S.C. §791a, *et seq*.).

***Public Interest***

The requester is a natural resource agency.

***Existing Information and the Need for Additional Information***

The Pre-Application Document does not contain any information about (1) the size range of American eels in the West Branch of the Penobscot River; or (2) timing of downstream migratory movements and rates of eels in the West Branch. This information gap needs to be filled, as it relates directly to (1) more fully understanding survival estimates which will be provided via the requested *Downstream American Eel Passage Assessment*; and (2) when downstream passage and protection measures need to be operated.

***Nexus to Project Operations and Effects***

The timing of downstream migration of adult eels is not defined for the West Branch of the Penobscot River and there is not information about the size of the eels attempting to move downstream past the six projects that comprise Ripogenus and Penobscot Mills. Therefore, the general effects of hydroelectric project operations on eel survival to the ocean are unknown. Although separate study requests have been submitted to address project-specific downstream passage route selection, delays, and mortality of eels, general characteristics (size) of eels moving downstream and of river flow and environmental conditions may have significant relationships with project operation and eel migratory success and survival. For example, eels may tend to move immediately before or during periods of significant precipitation (or consequently river flow), times at which projects may be generating at maximum capacity or spilling, which may, or may not, present a higher passage risk to eels. Conversely, periods of low flow may be associated with a significant proportion of total river flow passing through turbine units, which present additional, or different, passage risk to eels. If discrete conditions which

promote eel downstream migration are known, it may be possible to take actions with respect to project operations which reduce or minimize passage risk (i.e., operation of a bypass, reduction of intake approach velocities, directed spillage through a particular route at a project, etc). These studies should provide baseline information on river-specific downstream migration to predict when silver-phase eels are expected to migrate downstream in the West Branch, from which project operations could be modified to minimize passage risks.

***Methodology Consistent with Accepted Practice***

Quantification of downstream movements of American eels in river systems requires systematic sampling of migrants throughout the migratory season. This can be accomplished with traditional active trapping methods (i.e., fyke or stow net sampling, weirs, or eel racks). Passive monitoring of migrant eels using hydroacoustic methods offers an alternative to active trapping. However, this form of passive monitoring requires verification of potential acoustic targets with some level of active (collection) or visual (traditional optical or acoustic video) sampling.

The Applicant will need to identify at least two potential locations that offer opportunities to conduct simultaneous passive and active sampling. Each location will need to possess a route of downstream passage which conducts a significant proportion of river flow and each would need a proximal bypass equipped with a sampler so that fish can be concentrated/collected from the passage route and identified to species. Project operations will influence the relative proportion of flow (and thus numbers of downstream migrant eels) in each passage route, so numbers of eels sampled in each route represent only a proportion of the total number of eels migrating downstream within the entire river. Since the absolute proportion of eels using a specific route at any one time is unknown, numbers of eels quantified within a route must serve as a relative index of the degree of migratory movement.

This study should quantify eel movements for two consecutive years since environmental conditions strongly influence migratory timing of eels, which can vary significantly from year to year (Haro 2003). Eels should also be measured during both study seasons, throughout the downstream passage season.

Eels will be quantified using methods similar to Haro et al. (1999), by continuously monitoring a fixed location at the projects with hydroacoustics. Since eels tend to concentrate in areas of dominant flow (Brown et al. 2009; EPRl 2001), the zone to be monitored should pass a dominant proportion of project flow throughout most periods of operation (i.e., forebay intake areas). Hydroacoustic monitoring shall encompass the entire potential migratory season, beginning in mid-August and ending in mid- December, and shall operate 24 hours per day. Data will be recorded for later processing and archiving.

Systematic active quantification of eels at downstream bypass samplers shall be performed simultaneously with passive hydroacoustic monitoring, to verify presence of eels and relative abundance of eel-sized hydroacoustic targets from the hydroacoustic data as well as the sizes of the eels collected.[9] Although daily operation of the bypass sampler could be performed, a more

[9] If all eels are not sampled, and a subset are measured for morphometrics, a power analysis will need to be performed that determines the most suitable sample size for this effort.

comprehensive technique is to monitor eels entering the bypass with an acoustic camera (i.e., DIDSON, BlueView, etc.). The acoustic camera will afford positive visual identification of eels as they enter the bypass, which is a concentration point for migrating eels. Acoustic camera monitoring will also allow monitoring to be performed 24 hours a day, and will be relatively unaffected by water turbidity
(which influences effectiveness of traditional optical video monitoring). The acoustic camera system will be operated during the same time period as acoustic monitoring, and images will be recorded for later processing and archiving.

Data analyses of size of eels, hydroacoustic, acoustic camera, bypass sampling, and environmental/ operational data will follow standard methodology.

Each project's operations (flows, levels, gate openings, number of units operating and operation level) and environmental conditions (river flow, temperature, turbidity, air temperature, precipitation) will be monitored regularly (hourly measurements if possible) throughout the duration of the studies.

***Level of Effort/Cost, and Why Alternative Studies Will Not Suffice***

The level of cost and effort for the downstream migrant eel migratory timing study would be moderate, given the level of cost for instrumentation, deployment, and data review/analysis. Cost is estimated at $50,000 per year for the study. No alternatives are proposed.

# Freshwater Mussel Survey
(Ripogenus, P-2572; and Penobscot Mills, P-2458)

***Goals and Objectives***

The goal of this study is to determine which freshwater mussels inhabit project-affected areas. A freshwater mussel survey was last performed in parts of the West Branch by Maine Inland Fish and Wildlife (IFW) in 2009.

The objective of the study will be to characterize the distribution and abundance of freshwater mussels in the impoundment, the bypass reach, and riverine reach downstream of the tailrace affected by project operations (including, but not limited to, Upper Gorge, Holbrook Side Channel, Back Channel, Millinocket Stream, etc.).

Should any federally listed, or priority at-risk species, be found at the East Millinocket Development, Dolby Development, Millinocket Development, North Twin Development, Millinocket Lake Storage Development, or Ripogenus dam the Service reserves the right to request an Instream Flow Incremental Methodology study to assess the impacts of the range of the proposed project discharges on the wetted area (and optimal habitat) for these species.

***Resource Management Goals***

The Service seeks the accomplishment of a number of resource goals and objectives through the licensing process for the Project. General goals include the following:

1. ensure that protection, mitigation and enhancement measures are commensurate with project effects and help meet regional fish and wildlife objectives for the basin; and
2. conserve, protect, and enhance the habitats for fish, wildlife, and plants that would be affected by the Project.

Specific to aquatic resources, the Service's goals are:

1. protect, enhance, or restore diverse high-quality aquatic and riparian habitats for plants, animals, food webs, and communities in the watershed and mitigate for loss or degradation of these habitats;
2. provide an instream flow regime that meets the life history requirements of resident fish and wildlife (including invertebrates such as freshwater mussels) throughout the project area; and
3. minimize potential negative effects of project construction, operation and/or maintenance activities on freshwater mussels that may inhabit the project area.

Our study requests are intended to facilitate the collection of information necessary to conduct effects analyses and to develop reasonable and prudent conservation measures, and protection, mitigation, and enhancement measures pursuant to the Endangered Species Act of 1973, as

amended (16 U.S.C. §1531 *et seq*.), the Fish and Wildlife Coordination Act, as amended (16 U.S.C. §661 *et seq*.), and the Federal Power Act (16 U.S.C. §791a, *et seq*.).

***Public Interest***

The requester is a natural resource agency.

***Existing Information and the Need for Additional Information***

The Pre-Application Document (PAD) provides limited information on the distribution or abundance of freshwater mussels within the West Branch of the Penobscot River/within the vicinity of the Ripogenus and Penobscot Mills projects (a freshwater mussel survey was last performed in parts of the West Branch by IFW in 2009). At that time, there were yellow lampmussel (*Lampsilis cariosa*) identified, but no brook floater (*Alasmidonta varicosa*), and tidewater mucket (*Leptodea ochracea*) was not mentioned. The Service notes, since the last survey performed by IFW, the brook floater has been deemed a priority at-risk species. Without an updated, robust, mussel survey, focused on project-affected areas, the Service cannot determine what, if any, measures are needed to ensure their protection.

***Nexus to Project Operations and Effects***

If mussels occur in the headpond, routine maintenance activities that require drawing the impoundment down could strand them, leaving them vulnerable to desiccation or predation. Likewise, the projects are not operated in instantaneous run of river mode, resulting in rapid flow fluctuations downstream of the tailrace. Freshwater mussels are relatively sessile animals and therefore susceptible to desiccation and/or predation if water surface elevations recede too quickly and/or drop too low.

According to the PAD, the distribution and abundance of freshwater mussels, within the West Branch, has not been assessed since 2009 and, based on Figure 5.4-4 in the PAD, all areas of concern to the agencies (related to any potential project-affected river reaches) have not previously been surveyed.

Updated information on the distribution and abundance of freshwater mussels, including the brook floater, in the vicinity of the Projects is needed in order to determine the impact project operations may have on these aquatic invertebrates.

***Methodology Consistent with Accepted Practice***

The Service requests a mussel survey be conducted at each dam associated with Ripogenus and Penobscot Mills. Since field identification of freshwater mussels can be quite difficult, we recommend that the Applicant hire a freshwater mussel expert to perform the assessment.

In general, the surveyor(s) should use snorkel or dive equipment to perform the assessment (depending on the depth of water). The impoundment effort should focus on the upstream extent of the headpond as well as littoral areas down to the lowest expected elevation during current

peaking operations and routine drawdowns for maintenance. Each bypass reach in its entirety should be surveyed. Downstream of each tailrace, the survey should focus on near-bank areas, island complexes/shoals, riffles, and shallow runs (i.e., those habitats most likely affected by flashboard failure and SAR operations). Results should include the number of each mussel species observed, the location and condition of each mussel, and the habitat in which it was found.

Should any federally listed, or priority at-risk species, be found at the East Millinocket Development, Dolby Development, Millinocket Development, North Twin Development, Millinocket Lake Storage Development, or Ripogenus dam, the Service reserves the right to request an Instream Flow Incremental Methodology study.

***Level of Effort/Cost, and Why Alternative Studies Will Not Suffice***

The expected level of effort and anticipated costs will be comparable to those experienced on similar FERC projects of this size, overall costs may range $20,000 to $30,000. No alternatives are proposed.

# Terrestrial Wildlife and Botanical Resources Study
(Ripogenus, P-2572 and Penobscot Mills, P-2458)

***Goals and Objectives***

The goal of this study is to (1) to characterize and describe the terrestrial wildlife and botanical resources that are currently representative of upland habitats within, and adjacent to, the Project's boundaries to evaluate potential project impacts from current or future operations and maintenance activities; and (2) compare baseline data collected during the last licensing proceeding with current conditions of the terrestrial, wildlife, and botanical resources community distribution (and data collected for other species, and their diversity, as relevant).

The specific objectives of the field study, at a minimum, include:

1. survey and inventory overall existing upland wildlife habitats;
2. note the occurrence of wildlife sightings during the course of the surveys;
3. survey and inventory vegetation cover classes and land use;
4. survey and evaluate the presence of targeted rare threatened or endangered species or associated habitats;
5. survey and inventory the nature and extent of upland invasive and exotic vegetation species; and
6. compare the current species diversity and distribution with the species diversity and distribution collected during the last licensing proceeding.

***Resource Management Goals***

The Service seeks the accomplishment of a number of resource goals and objectives through the relicensing process for the Project. General goals include the following:

1. Ensure that protection, mitigation and enhancement measures are commensurate with Project effects and help meet regional fish and wildlife objectives for the basin.

2. Conserve, protect, and enhance the habitats for fish, wildlife, and plants that continue to be affected by the Project.

Specific to terrestrial wildlife and their habitats, the Service's goals are:

1. Protect, enhance, or restore diverse high quality terrestrial habitats for plants, animals, food webs, and communities in the watershed and mitigate for loss or degradation of these habitats.

2. Minimize existing and potential negative Project effects of ongoing operation and/or maintenance activities on terrestrial wildlife and vegetation.

3. Protect habitat important to the persistence of the federally threatened northern long-eared bat (*Myotis septentrionalis*) (NLEB) and Canada lynx (*Lynx canadensis*) within the Project boundary.

Our study requests are intended to facilitate the collection of information necessary to conduct effects analyses and to develop reasonable and prudent conservation measures, and protection, mitigation, and enhancement measures pursuant to the Endangered Species Act of 1973, as amended (16 U.S.C. §1531 *et seq*.), the Fish and Wildlife Coordination Act, as amended (16 U.S.C. §661 *et seq*.), and the Federal Power Act (16 U.S.C. §791a, *et seq*.).

***Public Interest***

The requestor is a natural resource agency.

***Existing Information***

Appendix F of the Pre-Application Document (PAD) lists the plant species that existed at Ripogenus and Penobscot Mills in the early 1990's, information that was collected during the last relicensing. However, there is no information in the PAD pertaining to how botanical resources may have changed over time. Further, while Table 5.5-5 and 5.5-6 provides a list of invasive plants found within the state of Maine, none are explicitly identified as occurring within the Ripogenus and Penobscot Mills project areas. Likewise, the lists of mammals, birds, amphibians and reptiles are only those that may occur at each development associated with each of the six developments.

These information gaps need to be filled so that the resource agencies can assess any potential impacts related to project operations and develop adequate protection measures to meet management goals and objectives. Plants and wildlife occurring in habitats in the project areas may benefit from protection, mitigation, and enhancement measures, given the potential effects of current and future operations and maintenance activities.

***Nexus to Project Operations and Effects***

The Project area contains habitat suitable for the Northern Long-Eared Bat and may contain habitat suitable for Canada lynx and their designated critical habitat and, according to the PAD, multiple State-listed species may occur in the vicinity of the projects (at all six developments). GLHA states it is not proposing any new construction, changes to current land management practices, or new land management activities as part of this licensing proceeding. However, the PAD provides no description of the types of land management practices that GLHA currently employs. Without knowing what terrestrial resources currently exist and what wildlife occurs in the project areas (or what types of land management and/or maintenance activities GLHA routinely undertakes) the Service is unable to determine if impacts are currently occurring or if they may occur under any new conditions that could be imposed via a new license (e.g., additional recreational amenities such as trails).

***Methodology Consistent with Accepted Practice***

The Service recommends that GLHA follow the methodology detailed in FirstLight's Study Plan 3.4.1, as described in the Revised Study Plan for the Turners Falls Hydroelectric Project (No. 1889) and Northfield Mountain Pumped Storage Project (No. 2485) filed with the Commission on August 14, 2013. Pursuant to the Study Plan Determination issued on September 13, 2013, the Commission approved FirstLight's proposed methodology; therefore, it is consistent with accepted practice.

In general, the study should consist of two tasks. The first task is a literature review to collect information needed to develop vegetation type maps and calculate the percentage of each vegetation type present (including any coarse woody material) in the study area. The second task is to conduct field surveys to document wildlife habitat and occurrence, vegetative cover types, and invasive plant species in the project areas.

According to the PAD, there are known bald eagle nesting and roosting sites along the impoundments associated with the projects. During field surveys, biologists should conduct surveys of bald eagle nests, feeding concentrations, and roosting sites using standard aerial methodology used by state and federal wildlife agencies. Aerial nest surveys should be conducted annually within a half mile of the shoreline of wetlands, rivers, streams, and beaver flowages in April of 2022 and 2023. Where encountered, bald eagle nests and roosting trees should be GPS-located and photo-documented.

The study report should include:

1. maps of the project areas showing locations and extent of habitats, vegetative cover, locations of invasive species, and known eagle roosting and nesting trees (as both polygons and point locations, as appropriate);
2. forest stand maps showing information like stand tree composition, age, height, and stocking density to determine if lynx habitat is present with the Ripogenus and Penobscot Mills project areas;
3. tabular summaries of the data;
4. an assessment of project effects (operations, maintenance activities, potential future recreational amenities, etc.) on terrestrial habitat, wildlife, and habitat connectivity at the Projects;
5. recommendations for any necessary plant, habitat type, or wildlife protection and/or invasive species control measures, including riparian buffer restoration and protection of key nest and roost trees for bald eagles.

***Level of Effort/Cost, and Why Alternative Studies Will Not Suffice***

This study will likely take two seasons to complete. A similar study being undertaken by FirstLight as part of the relicensing of its Turners Falls (FERC No. 1889) and Northfield Mountain Pumped Storage (FERC No. 2485) projects was estimated to cost $60,000 to $80,000.

As the scope of the two studies are similar in size, the Service estimates it will cost GLHA $60,000 to $80,000 to complete the requested study. No alternatives are proposed.

GLHA Study Request #9

# Northern Long-Eared Bat Acoustic Survey
(Ripogenus, P-2572; and Penobscot Mills, P-2458)

***Goals and Objectives***

The goal of this study is to determine whether the Northern Long-Eared Bat (NLEB) is present within the Ripogenus and Penobscot Mills Project boundaries.

The specific objective of the field study is to conduct an acoustic survey for NLEB during the summer period to document presence/absence of the species.

***Relevant Resource Management Goals***

The Service seeks the accomplishment of a number of resource goals and objectives through the relicensing process for the Project. General goals include the following:

1. Ensure that protection, mitigation and enhancement measures are commensurate with Project effects and help meet regional fish and wildlife objectives for the basin.

2. Conserve, protect, and enhance the habitats for fish, wildlife, and plants that continue to be affected by the Project.

Specific to the NLEB, the Service's goals are:

1. Protect, enhance, and restore diverse foraging and roosting habitat (maternity and non-maternity) for the NLEB.

2. Avoid NLEB mortality by conducting tree removal outside the time of year NLEBs are utilizing forest habitats for roosting (April 20 through October 15).

The NLEB is a federally threatened species. As such, this study request is intended to facilitate the collection of information necessary to conduct effects analyses and to develop reasonable and prudent conservation measures, and protection, mitigation, and enhancement measures for the species pursuant to the Endangered Species Act of 1973, as amended (16 U.S.C. §1531 *et seq*.).

It is the goal of the Service to recover the NLEB so that it can be removed from the list of threatened species in the future. An acoustic survey may also provide some information regarding the presence of the little brown bat (*Myotis lucifugus*) and tri-colored bat (*Perimyotis subflavus*) within the project boundaries. Both species are currently undergoing consideration for listing by the Service under the Endangered Species Act.

***Background and Existing Information***

Although bat survey work in Maine has typically been rather limited and we are not aware of any prior surveys on Project lands, mist-netting surveys conducted in several locations in Piscataquis County in 2006 and 2008 captured several NLEB indicating that the species could be present. The Pre-Application Document (PAD) indicates NLEB has been documented as a species potentially occurring in the vicinity of the projects and based on the vegetative community descriptions in the PAD, the project areas likely contain habitat suitable for the NLEB. However, baseline information regarding the presence/absence and distribution of the NLEB within the Project area is lacking. These data are needed in order to meet the goal of evaluating project effects. If NLEBs are present within the project area, they may benefit from protection, enhancement, and mitigation (PME) measures, given the potential effects of current and future operations and maintenance or enhancement activities on project lands.

***Nexus to Project Operations and Effects***

The Project consists of the East Millinocket Development, Dolby Development, Millinocket Development, North Twin Development, Millinocket Lake Storage Development, and Ripogenus dams. Based on vegetative community descriptions provided in the PAD, the project areas likely contain habitat suitable for the NLEB. While GLHA acknowledges that the NLEB may exist in the Project vicinity, it maintains that continued operation of the Project is unlikely to have any effect on NLEB populations. Even though GLHA is not proposing any new construction, land management activities that could impact bat habitat or hibernacula could change as a result of the relicensing process. For example, additional recreational trails could be a requirement of any new license issued for the projects. Those trails could require that trees be cut, which could result in bat mortality if the removal occurs during a time when bats are unable or unwilling to flee a tree that is felled when they are inside. Without knowing if, and where, NLEBs occur within the project areas, the Service cannot determine if existing operations (e.g., maintenance activities on project lands) or future activities could result in adverse effects to NLEB populations.

***Methodology Consistent with Accepted Practice***

The Service requests that GLHA conduct a bat survey following the Service's current-year summery survey protocol for the NLEB, which can be found at the following website: https://www.fws.gov/midwest/endangered/mammals/inba/inbasummersurveyguidance.html.

In general, survey methodology should consist of having a qualified acoustic surveyor conduct acoustic surveys during the summer period (May 15 through August 15). In accordance with Service guidance, non-linear projects should have a minimum of four detector nights per 123 acres of suitable summer habitat, with two detector locations per 123-acre "site" being sampled until at least four detector nights have been completed over the course of at least two calendar nights.

To maximize the quality of recorded echolocation calls, detectors should be positioned at least 1 meter off of the ground, at an angle ≥45 degrees, and with PVC tube weatherproofing. The

acoustic sampling period for each site must begin at sunset and end at sunrise each night of sampling.

Data analysis should consist of using currently available approved[10] acoustic bat identification programs to determine if positive detections of NLEB calls were recorded.

A report of the acoustic survey results should include:

- an explanation of any modifications from the original survey plan;
- a description of acoustic monitoring sites, survey dates, duration of survey, weather conditions, and a summary of findings;
- a map identifying acoustic monitoring locations and a corresponding table including the GPS coordinates;
- a table with information on acoustic monitoring and resulting data, including detector GPS coordinates, survey dates, survey hours;
- detailed analysis and results of any qualitative acoustic analysis conducted where a program(s) considered NLEB presence likely, including justification for rejecting any program MLE results (if applicable); and
- photographs of each acoustic site documenting the location of the detector, the orientation of the detector, and the detection cone.

The methodologies described here are consistent with commonly accepted practices.

***Level of Effort/Cost, and Why Alternative Studies Will Not Suffice***

The study should take one field season to complete. The level of effort required is moderate. Given the amount of potentially suitable habitat, the Project area may contain 10 or more survey sites with 40 or more detector nights. The Service estimates it will cost GLHA $20,000 to $40,000 to complete the requested study. No alternatives are proposed.

[10] Currently approved bat identification software programs to be used in conjunction with the NLEB presence/absence summer survey protocols can be found at the following website: https://www.fws.gov/midwest/Endangered/mammals/inba/surveys/inbaAcousticSoftware.html.

Re: Project Number: 2572-133, Docket Number: P-2572 and Sub Docket Number: 133
Ripogenus Dam

Dear Ms. Bose:

We purchased our camp on Timberland Road on Caribou Lake as a retreat for fishing, boating and other recreational water uses.

The water level of Caribou Lake in the past 2 years has been lowered to a point where we are unable to navigate with our boat up into Chesuncook Lake. As of July 4th weekend 2021, the shorefront was approximately 200 feet from the shoreline. In previous years, it was less than half the distance during the same time frame. We are unable to launch our 16-foot boat at our location or at the public boat launch provided by Brookfield off the Golden Road due to such low lake levels. The low water level has also impacted our ability to get water to the camp.

Other lakes in the Penobscot watershed have seasonal draw down limits, i.e. North & South Twin Lake. We respectfully request that similar limitations on the drawdowns by the dam be limited to certain thresholds at certain times of the year as with these other lakes.

If the lake levels continue to drop, the value of our property will be negatively affected. We hope that F.E.R.C. will take into consideration public use of the lake and waterways that we so strongly support and enjoy.

Thank you for your consideration.

Sincerely,

Curt & Emelie Ferland

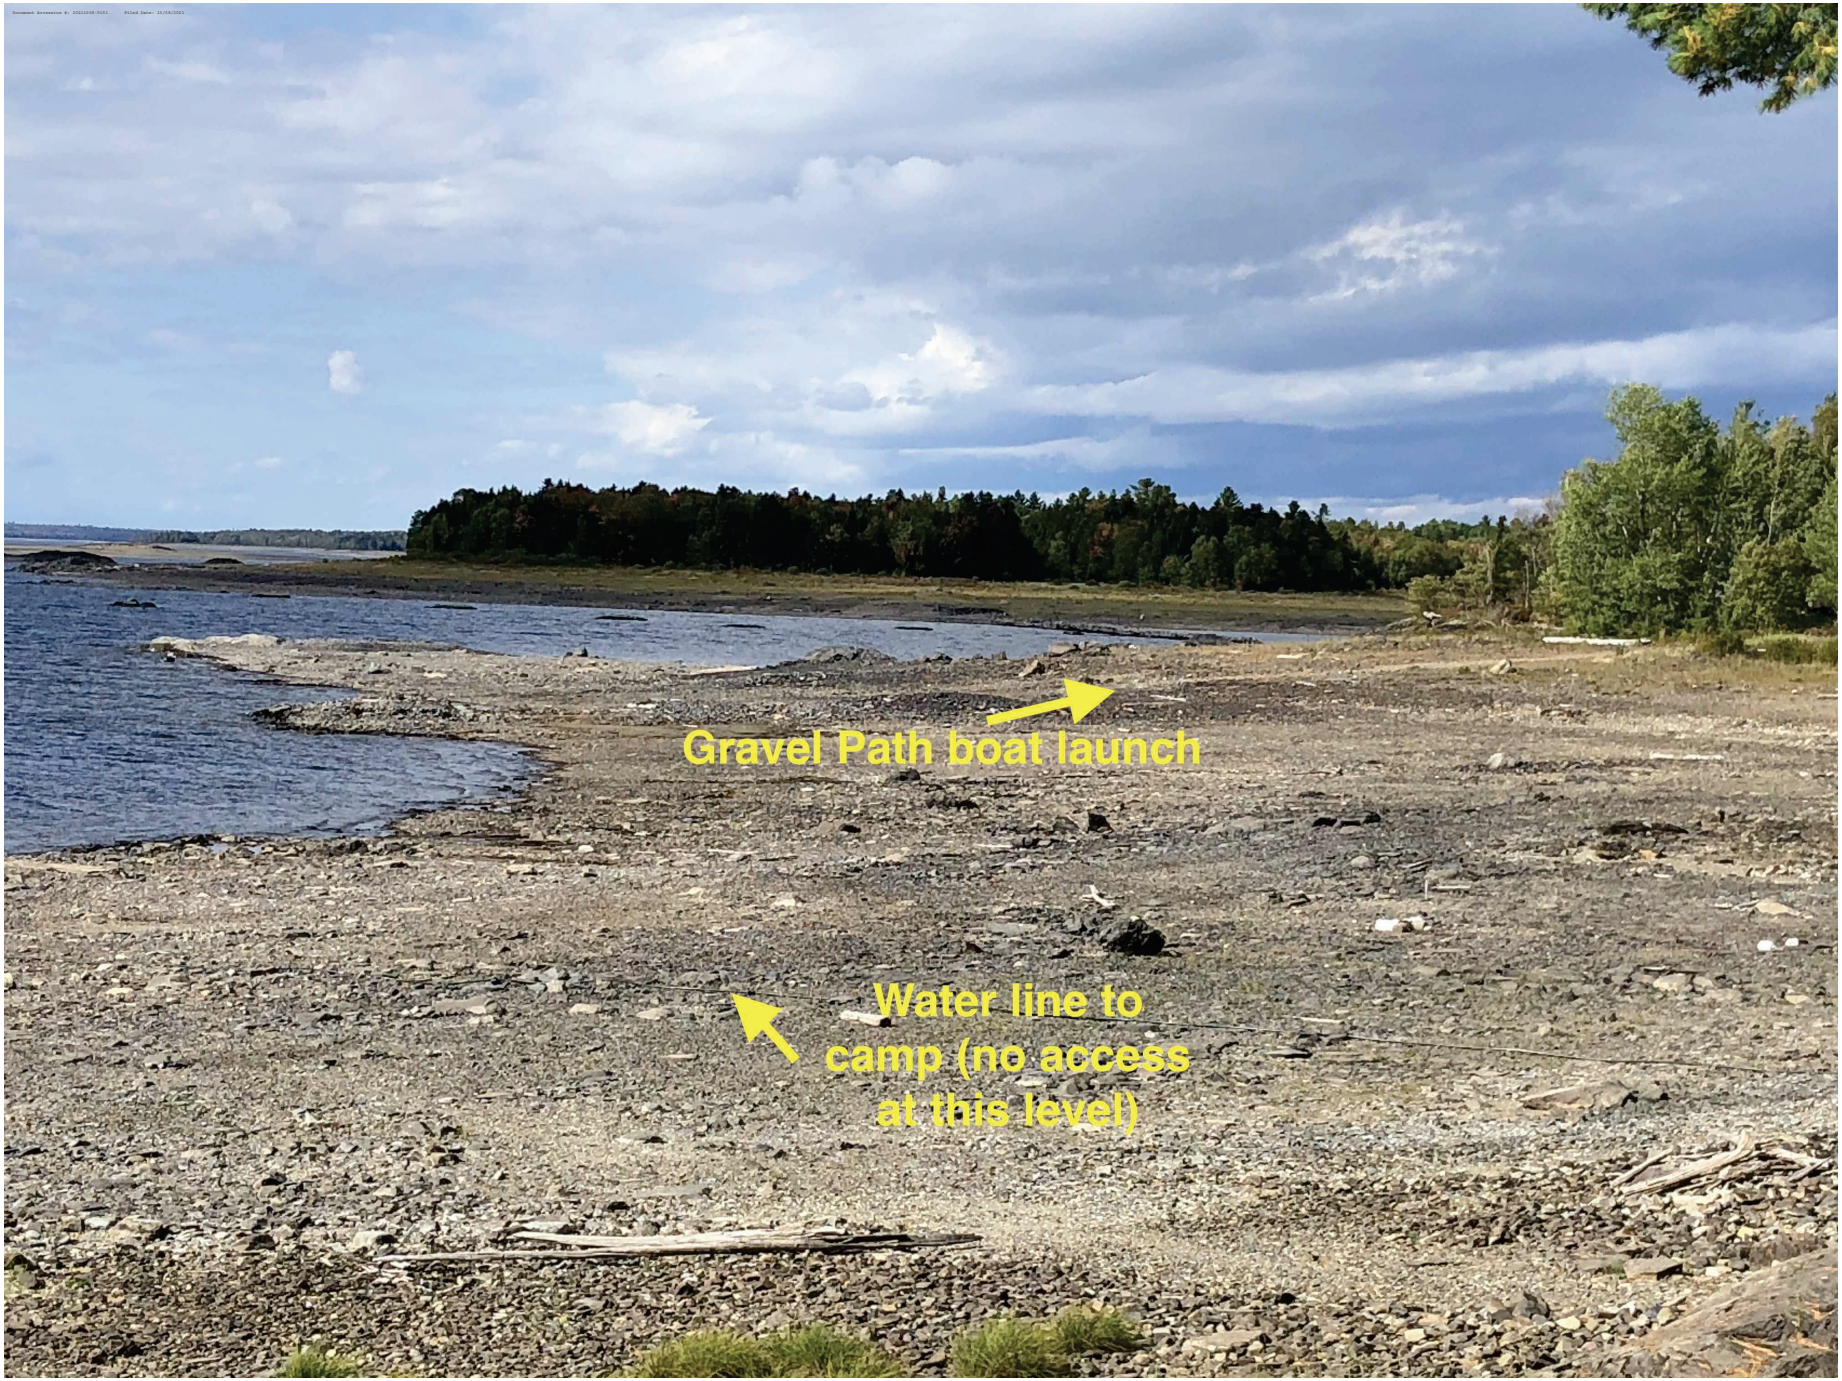
October 7, 2021

Kimberly D. Bose
Secretary
Federal Energy Regulatory Commission
888 First Street, N.E. Washington DC 20426

Dear Secretary Bose,



I'm writing today to provide comments on the PAD over the relicensing of the Ripogenus Hydroelectric Project (P-2572-133). I currently serve as the primary caretaker of our family's recreational camp on Chesuncook lake, which has been in our family since my grandfather purchased the camp in March of 1983. I have been visiting this incredible place for the past 30+ years and have many fond memories of fishing, viewing wildlife, and learning from the generations before me at our remote cabin in the North Maine Woods.

Over the past several years we have seen declining lake levels over the summer months that have greatly impacted the use of Chesuncook lake in a recreational manner during the late summer and early fall months. The drastic lowering of lake levels over the summer have introduced navigational hazards in the form of large rocks, emergence of rock pilings (including the existing retired dam leading from Chesuncook to Ripogenus lake), and submerged stumps/logs. The emergence of these hazards, which in former years have been far under water, has resulted in damage to my boat in the form of dented hulls and motor damage, specifically propeller damage. Additionally, the lowering of the lake to the levels seen in the past few years makes traveling from Chesuncook to both Caribou and Ripogenus Lakes nearly impossible. Admittedly, low snow melt and runoff the past two springs have failed to "fill" the lake in the spring months leading to even lower lake levels in the late summer/fall of both 2020 and 2021 (pictures included for reference). In addition to these navigational hazards, access to public campsites managed by the Department of Conservation becomes very difficult and recreational boat access to the lake becomes essentially non-existent. The current relicensing plan details that GLHA will "continue to operate and maintain the 11 recreation sites", which includes the public launch at Chesuncook lake as well as the boat "put-in" on Caribou lake. Under the current proposed renewal plan, the public launch at Chesuncook lake has not been "maintained" in many years and with current draw down of the lake, was not accessible for boats larger than 16 feet in the fall of 2020 and 2021 (for reference, my boat is 19 feet, and I am unable to launch this boat at this public access point). As currently written, the PAD would allow for a targeted seasonal draw down range of 28 feet. If this plan were to continue, we will continue to see an inability to utilize this watershed for recreational purposes given the above mentioned hazards. Futhermore, the current draw down allowance specified in the PAD shows the contrast between the draw down plan at Chesuncook lake compared to other large lakes in the region. Even within this same document, the required level of North Twin Lake is set to be within one and one half feet of full from Memorial Day until the end of August and no more than 3.5 feet by October. I ask that a similar draw down restriction be placed on the Ripogenus impoundment as well, being the upstream source of the North Twin Watershed.

I would like to advocate that the relicensing plan requires GLHA to partner with state/federal agencies as well as conservation groups (including but not limited to the Department of Conservation Bureau of Parks and Lands, Maine Department of Inland Fisheries and Wildlife, U.S. Fish & Wildlife Service, Trout Unlimited, and others) to conduct additional impact studies on the fisheries and wildlife in the Ripogenus watershed. The scoping document states that GLHA will continue to support and collect information on impact of aquatic resources, wildlife and botanical resources, and recreational resources. The data included within the PAD is not up to date and photographs do not reflect the current state of the lake, nor the public access to the lakes. I would specifically like to request impact studies as they pertain to ongoing management projects by the Maine Department of Inland Fisheries and Wildlife surrounding Landlocked Salmon populations in the watershed. The low water levels seen in the past several fall seasons certainly put stress on fish spawning areas, but we do not know what the true impact is without fisheries studies.

Thank you for your time and for taking my comments into consideration.

Great Lakes Hydro America, LLC
Application for New License

Ripogenus Hydroelectric Project
FERC No. 2572

Penobscot Mills Hydroelectric Project
FERC No. 2458

# AMERICAN WHITEWATER AND APPALACHIAN MOUNTAIN CLUB COMMENTS & STUDY REQUESTS IN RESPONSE TO NOTICE OF INTENT TO FILE LICENSE APPLICATION, FILING OF PRE-APPLICATION DOCUMENT (PAD), COMMENCEMENT OF PRE-FILING PROCESS, AND SCOPING; REQUEST FOR COMMENTS ON THE PAD AND SCOPING DOCUMENT, AND IDENTIFICATION OF ISSUES AND ASSOCIATED STUDY REQUESTS REGARDING THE RIPOGENUS HYDROELECTRIC PROJECT (P-2572) AND PENOBSCOT MILLS HYDROELECTRIC PROJECT (P-2458)

American Whitewater ("AW") and Appalachian Mountain Club ("AMC") submit the following Comments and Study Requests in response to the filing of the Pre-Application Document (PAD) for the Ripogenus Hydroelectric Project and Penobscot Mills Hydroelectric Project (FERC Project Nos. P-2572, P-2458) by Great Lakes Hydro America, LLC ("GLHA") Collectively, these projects are located on the West Branch of the Penobscot River and Millinocket Stream and are comprised of the Ripogenus Hydroelectric Project and the Millinocket Lake Storage, North Twin, Millinocket, Dolby, and East Millinocket developments as part of the Penobscot Mills Hydroelectric Project. While GLHA holds separate licenses for the Ripogenus and Penobscot Mills projects, the licensee has appropriately filed a joint Pre-Application Document, because GLHA is the licensee for both projects, they have the same license expiration date, and the operations of both projects are inextricably linked. Inasmuch as these projects have cumulative impacts on both developmental and non-developmental resources, we are filing these comments and study requests as a single document under each FERC docket to support a coordinated approach to the relicensing of these projects and to advocate for the preparation of a single NEPA document addressing the cumulative impact of all six developments.

American Whitewater is a national non-profit 501(c)(3) river conservation and recreation organization founded in 1954. With approximately 6,000 members and 100 affiliate clubs, representing tens of thousands of whitewater paddlers across the nation, American Whitewater's mission is to protect and restore our nation's whitewater resources and to enhance opportunities to enjoy them safely. Our members are primarily conservation-oriented kayakers and canoeists, many of whom live and/or engage in recreational boating in the New England region within easy proximity of the Penobscot River. American Whitewater has long been involved with the FERC licensed hydropower projects in the Maine, including hydropower projects located on the Penobscot, Kennebec, Rapid, and Magalloway rivers, and are party to settlement agreements that provide for whitewater boating opportunities that partially mitigate for project impacts.

Since 1876, the Appalachian Mountain Club has promoted the protection, enjoyment, and understanding of the mountains, forests, waters, and trails of the Appalachian region. AMC is the largest conservation and recreation organization in the Northeast with more than 90,000 members, supporters, and advocates, many of whom visit the lands and waters upstream and downstream of the projects for recreation.

## Comments

The West Branch of the Penobscot River is one of the nation's premier natural, scenic, and recreational wonders. Water flowing over many millennia has sculpted the bedrock, river channel and landscape from the Ripogenus Gorge to Millinocket into a series of remarkable geological and scenic features that make this river a unique recreational and natural resource. The continued operation of large hydroelectric power plants, dams and other associated structures degrades the public's use and enjoyment of this unique and spectacular public resource.

## Project Facilities and Operations

From the top of the Ripogenus impoundment to the East Millinocket tailrace, these storage projects and hydropower dams impact more than 40 river miles of the West Branch of the Penobscot River and more than 12 river miles of Millinocket Stream. The uppermost development, Ripogenus Hydroelectric Project, obstructs more than 20 miles of the West Branch of the Penobscot River by diverting flows at the Ripogenus Dam into a 3,850-foot-long penstock leading to the McKay Station powerhouse. The drainage area at the project is 1422 sq. mi. The flow diversion at Ripogenus Dam regularly diverts nearly all flows from the West Branch of the Penobscot River, virtually dewatering the Ripogenus Dryway or Upper Gorge of the natural river channel other than an unnatural steady state minimum flow of 100 cfs from July 1 to September 30 to attract adult salmon for recreational fishing during the summer months. At other times, GLHA leaves the Upper Gorge dewatered except for leakage of 12 cfs.

The minimum flow in the bypassed reach is 0.07 cubic feet per second per square mile (cfsm) of the drainage area during the summer months and 0.008 cfsm during the rest of the year, far below the United State Fish and Wildlife Service recommended base flow of 0.5 cfsm necessary to support healthy aquatic habitat. The flow diversion and dewatering of the natural river channel below the Ripogenus Dam impacts aquatic habitat, obstructs river connectivity, reduces sediment transport, degrades water quality, reduces recreation opportunity, and degrades the aesthetic quality of the Ripogenus Dryway.

From the top of the Ripogenus impoundment to the McKay Station tailrace, the dewatered natural river reach drops about 84 feet over the .75-mile natural river channel. While the licensee does not include a description of the geologic features in the bypassed reach, imagery of and accounts by whitewater paddlers of this reach shows that this river reach contains a continuous series of ledges and features that provide high-quality whitewater boating opportunity when sufficient flows are provided. Additionally, the licensee acknowledged in its prior license application that the Upper Gorge is an aesthetic feature in the project boundary that draws

visitors to the project to hike and view the falls in its present dewatered condition. There are no scheduled whitewater boating releases in the Dryway, and the licensee does not provide information on the frequency with which flows are spilled into the natural river reach when the pond is full, and inflows exceed the 3500 cfs combined capacity of the three turbines at McKay Station. McKay Station is a 38.6 MW powerhouse that operates in hydropeaking mode by fluctuating the upstream impoundment. Given the allowable impoundment drawdown of 44 feet at Ripogenus and the licensee's interest in avoiding spillage, we assume that spillage into the Upper Gorge is infrequent outside of the spring freshet.

The lack of publicly available Chesuncook lake elevation information and historic flow data at Ripogenus makes it difficult to assess the impact of project operations on flows below McKay Station. Based on the information provided in Figure 4.4-1 in the PAD, project outflows can be as low as 400 cfs when the project trips offline, an increasingly common occurrence. More commonly, the project releases a minimum flow of 1000 – 1400 cfs depending on the time of year to support fish spawning, incubation, and habitat. In addition, the licensee releases flows ranging from 1800 – 2300 cfs to provide recreational boating opportunity from May through September during daytime boating hours. The frequency with which the licensee exceeds these minimum flows is unknown, and we look forward to the licensee providing historic operational flow data through the relicensing process so that we can more fully evaluate the impact of project operation on non-developmental resources.

Below McKay Station, project outflows cascade over the 15-mile premier whitewater boating reach between McKay and Debsconeag before flowing into Ambajejus Lake in the North Twin Development impoundment and diversion dam located 21 miles below McKay Station. Like McKay, North Twin is a peaking operation relying on storage from the four lakes that comprise its impoundment. North Twin impoundment lake levels fluctuate throughout the year from 1.5 feet after spring refill to 3.5 feet during the late summer to 12 feet or more during the winter months. Flows into the North Twin Impoundment come from releases from Ripogenus and tributary inflow as well as water pumped from the Millinocket Lake Storage Development.

Flows into North Twin are augmented by the Millinocket Lake Storage Development pumping water into Ambejejus Lake in support of hydropeaking operations at North Twin. Impoundment levels at Millinocket Lake Storage Development fluctuate 10 feet because of its pumping for North Twin Station as well as the release of an unnatural steady state minimum flow of 60 cfs from Millinocket Lake Dam into the 9.4-mile reach of Millinocket Stream between Millinocket Lake and Shad Pond below the Millinocket Development. The pumping at Millinocket Lake diverts flows that would otherwise be available for downstream flows on Millinocket Stream, eliminates natural flow variability beneficial to aquatic habitat and recreation, degrades water quality, and increases the hydropeaking on the West Branch of the Penobscot in the Penobscot Mills project area.

The North Twin Dam, located 33 miles below the Ripogenus Dam, is a 7 MW hydropower development with three turbines with a combined hydraulic capacity of 4500 cfs. The powerhouse, located adjacent to the North Twin Dam, operates in hydropeaking mode fluctuating flows from a minimum flow of 2000 of 3000 cfs up to the 4500 cfs hydraulic capacity of the project. Project outflows are released into a riverine reach leading to Quakish

Lake, the impoundment for the Millinocket Development located 2.6 miles below the North Twin Dam.

Inasmuch as Quakish Lake has negligible storage capacity, the licensee's characterization of its operations at Millinocket and the lower developments as run-of-river is misleading in several respects. The Penobscot Mills Hydroelectric Project is a hydropeaking project from North Twin to East Millinocket because each hydropower development is successively passing peaking flows from the upstream development. None of these developments can be characterized as run-of river because they generate power based on the peaking flow regime at North Twin and rely on the operational flexibility provided by the North Twin and Millinocket Lake storage reservoirs. Characterizing the Millinocket Development as run-of-river obscures the substantial impact of project operations by implying that it passes natural flows and protects the natural flow regime.

More significantly, the 37 MW Millinocket Development dams and diverts the West Branch of the Penobscot River at Stone Dam where the current license requirements fail to mandate any minimum or naturally variable flow into the 4.5-mile natural river channel of the Penobscot River leading to Shad Pond, a section of the Penobscot River that the licensee incongruously calls the "Back Channel". While the Licensee is required to release a minimum flow of 3000 cfs from North Twin Development from August 22 through October 15 and 2000 cfs from Shad Pond at other times, no minimum or naturally variable flows are passed at Stone Dam, leaving the natural river channel nearly dewatered at most times. The only flow in the natural river is from tributary inflow in the lower reach when available and at times when upstream flows exceed the 4305 cfs hydraulic capacity of the Millinocket powerhouse, primarily during the spring runoff as shown on the image below.

*West Branch of the Penobscot River Below Stone Dam Showing Spillage*

*West Branch of the Penobscot River Below Stone Dam at Grand Falls Showing Spillage*

Flows from Millinocket Development, Millinocket Lake Storage Development, and leakage or spill from Stone Dam converge on Shad Pond downstream from Millinocket Development with a required minimum flow of 2000 cfs leading to the Dolby impoundment. Like Millinocket, the licensee mischaracterizes the Dolby Development as run-of-river. In reality, the Millinocket, Dolby, and East Millinocket Developments, like Ripogenus and North Twin, are hydropeaking projects that successively pass altered flows from the upstream developments rather than passing unaltered flow or reregulating discharges to more closely mimic the natural flow regime.

The Dolby Development, located approximately 8 miles below the Millinocket Development and approximately two miles above East Millinocket Development, has a 16.5 MW powerhouse with a hydraulic capacity of 4350 cfs. According to the PAD, both Dolby and East Millinocket have negligible usable storage, although it is unclear from the PAD whether the Dolby Pond maintains a level impoundment. It appears that there is some level of fluctuation based on historical imagery. Flows from the Dolby tailrace flow into the West Branch of the Penobscot River to the 6.9 MW East Millinocket Development located 1.9 miles downriver. The Drainage area at East Millinocket is 2,111 sq. mi.. East Millinocket powerhouse has a combined hydraulic capacity of 4200 cfs.

**Impact of Project Facilities & Operations**

- Aquatic Habitat & Fish Passage

For more than a century, the dams on the mainstem and tributaries of the Penobscot River have decimated native species of sea-run fish including Atlantic Salmon and Shad. While efforts over the past two decades have resulted in the removal of the Veazie and Great Works dams, improvements to fish passage, and opening of hundreds of miles of habitat, the continued presence of hydropower dams continue to have deleterious effects on numerous fish species and recreation opportunity. The harm caused by the hydropower dams on the Penobscot is evident in the licensee's dams at East Millinocket, Dolby, Millinocket, North Twin, and Ripogenus. Once home to Atlantic Salmon, river herring, and other native fish species, what remains today is a managed fishery with landlocked Salmon, Rainbow Trout smelt, and warm water fish species. Restoration of the Penobscot River will require an assessment of each dam along the mainstem and tributaries to provide meaningful improvements for fish passage through the relicensing process.

Fish passage at the Penobscot Mills and Ripogenus hydroelectric projects is virtually nonexistent except for North Twin where passage is provided for landlocked Salmon between the Millinocket and North Twin impoundments. The dewatering of bypassed reaches below the Ripogenus and Millinocket dams has eliminated habitat that would be otherwise suitable for various species. The East Millinocket and Dolby projects lack any fish passage for river herring and there are no Shad in Shad Pond. Restoration of the river reach from the Ripogenus impoundment to the East Millinocket tailrace will require the restoration of flows to dewatered river reaches, installation of appropriate fish passage at each development, and the restoration of a Shad fishery in Shad Pond.

- Whitewater Boating

The West Branch of the Penobscot River is known internationally as among the most important rivers for whitewater boating in the Northeast and draws tens of thousands of whitewater boaters annually seeking to enjoy the scenic beauty of the Penobscot River and its dramatic rapids. Paddlers traveling to the Maine Woods region have a positive economic impact on the region and support the outdoor recreation economy, impacts that far exceeds the value of power generated by these hydroelectric projects.

The West Branch of the Penobscot River, where the projects are located, is treasured by local residents and visitors to the area who enjoy boating, angling, swimming and hiking throughout the recreation season. Eco-tourism and outdoor recreation form the foundation of the local economy, relying heavily on the resources impacted by these projects. Unfortunately, project facilities and operations diminish recreation opportunities on the West Branch of the Penobscot River, and diminish the natural beauty of the area, obstructing natural river flow, dewatering dramatic waterfalls, rapids and other sections of the natural river essential to the enjoyment of designated and existing uses of these rivers. AW and AMC have identified four sections of the West Branch of the Penobscot River located in the project boundaries for the Ripogenus and Penobscot Mills projects as providing high quality whitewater boating opportunities. These sections are as follows:

**Ripogenus Dryway:**

The section of the West Branch from Ripogenus Dam to McKay Station, known as the Upper Gorge or Ripogenus Dryway, is a .75-mile reach with sufficient gradient structure to provide a highly valuable whitewater boating opportunity with sufficient flow. This section of the West Branch cascades over a series of ledges and other geologic features through a remote, narrow gorge setting before paddlers enter the lower gorge below McKay Station. This section has been periodically run by paddlers during spillage from the Ripogenus Dam, demonstrating that this section should be considered a whitewater boating resource. Unfortunately, opportunities to boat this section are infrequent as they only occur when flows are above station capacity, or when the project is offline. The aesthetic quality of this reach also attracts hikers along the Upper Gorge Trail. While precise flow ranges for this section of the river are unknown, anectodical information from those who have previously boated this reach shows that the Ripogenus Dryway is boatable at flows at 400-2200+ cfs and provides flows in the Class III/IV range of difficulty. These flows within the normal operating range of the project and would require that the licensee forego generation and restore natural river flows in the Ripogenus Dryway.

*Ripogenus Dryway*

*Ripogenus Dryway at base flow conditions*

*Ripogenus Dryway from the crest of Ripogenus Dam*

*Ripogenus Dryway during a high flow event showing whitewater paddling features*

**McKay Station:**

The West Branch of the Penobscot River below McKay Station is the arguably the most renowned whitewater river in the northeast, its closest comparable river reach being the Gauley River in West Virginia. The upper section below McKay features a series of Class III – V rapids through the Penobscot Gorge and Cribworks sections to Big Eddy. This section of the West Branch is known for its powerful hydraulics, waterfall drops, stunning views of Mount Katahdin and frequent wildlife sightings. The 15-mile reach down to Debsconeag provides both rafters and private boaters with an unequaled boating opportunity in the region.

Under its current FERC license, the licensee is required to release daytime flows ranging from 1800-2300 between May 1 – October 1 with flows varying within this range depending on the day of week and hydrologic conditions. While this flow range is well utilized by both private boaters and commercial outfitters, the licensee has not conducted a controlled-flow whitewater boating study on this river reach using the widely accepted *Whittaker* protocols developed in 2005 to identify minimum acceptable and optimal flow ranges.

*Penobscot Gorge downstream of McKay Station*

*Cribworks Rapid on the West Branch of the Penobscot River near Telos Road*

*Rapids on the West Branch of the Penobscot River*

**Stone Dam:**

The Penobscot Mills Dryway or Stone Dam Dryway between Stone Dam and Shad Pond on the West Branch of the Penobscot River, is a 4.5-mile river reach that the licensee refers to as the "Back Channel", which has the potential to provide a highly valuable whitewater boating opportunity to paddlers with a wide range of abilities if sufficient flows were provided. Under current FERC license conditions, the licensee is not required to release any minimum flow into this lengthy river reach as all flows are diverted into the Millinocket powerhouse rather than flowing naturally into the river.

The flow diversion at Stone Dam and the dewatering of the 4.5-mile reach of the West Branch of the Penobscot River destroys aquatic habitat, obstructs sediment transport, reduces water quality, and eliminates valuable recreational boating and angling opportunities that would otherwise be available if sufficient flow were provided. This section of the river contains ample gradient and geologic features that would provide high quality aquatic habitat as well as whitewater boating and angling opportunities under appropriate flow conditions. The reach also contains Grand Falls, a significant geologic feature located 2.7 miles below Stone Dam. Rarely, flows are spilled over Stone Dam, except when upstream flows from North Twin exceed 4305 cfs and the impoundment is at capacity. Dewatered throughout the year except during high flows that are beyond the capacity of the project to store or generate power, the dewatered Grand Falls is a natural and recreational treasure along this reach significantly impacted by the projects.

Higher flows into the Back Channel can be released from an inflatable rubber flashboard system and is currently operated at times by deflating the pneumatic rubber flashboard system to provide flows of 200 cfs and then ramping up at an interval of 400 cfs an hour until downstream flow targets are met or until Stone Dam falls to 459.45 FTMSL.

This section of the West Branch has been run by numerous whitewater boaters when flows on the West Branch exceed the hydraulic capacity of the Millinocket Development. While this river reach is clearly boatable, minimum acceptable and optimal flow ranges are unknown, and the licensee has not previously performed a controlled-flow whitewater boating study using the widely accepted *Whittaker* protocols developed in 2005. Boaters previously paddling this reach have determined that this reach contains Class III/IV rapids that provide a high-quality whitewater boating experience under suitable flow conditions.

*Grand Falls on the West Branch of the Penobscot River below Stone Dam on the Penobscot Mills Dryway*

**Millinocket Stream:**

Millinocket Stream between Millinocket Lake and Shad Pond has the potential to provide whitewater boating opportunity if sufficient flows are provided. While there is no river gage and the licensee does not publicly release flow information on spill from the Millinocket Lake Dam, whitewater boating is an existing use on this 9.4-mile river reach during spill conditions. The licensee has not performed a controlled-flow whitewater boating study using the widely accepted *Whittaker* protocols, so precise flow ranges that would identify minimum acceptable and optimal flows are unknown. In its prior relicensing of the Penobscot Mills Hydroelectric Project, the licensee acknowledged the whitewater boating potential of this reach in response to FERC's AIR, stating that the reach between Millinocket Lake and Shad Pond is a recreational resource when flows greater than 250 cfs are released from the Millinocket Lake Dam including the Class III Locomotive Rips (or Choo-Choo Falls). While the information was solely based on a conversation with several boaters who previously paddled the reach, a more in-depth study is required to evaluate the recreational value of the resource more thoroughly.

**Consideration of Alternatives to Project Relicensing**

The licensee for the Ripogenus and Penobscot Mills hydroelectric projects have filed their Pre-Application Document with FERC and have stated their intent to seek new licenses that propose to continue existing operations for another 30-50 years. Relicensing provides FERC, resources agencies, NGOs and other stakeholders with an opportunity to explore alternatives to relicensing these projects under the current mode of operation. There is little doubt that many hydropower projects including some of these developments on the West Branch of the Penobscot River would not be constructed today due to their environmental impacts. We urge the licensees for these projects, state, and federal resource agencies responsible for evaluating environmental

impacts, and FERC as part of its NEPA review and economic valuation analysis to consider alternatives to relicensing including project decommissioning and dam removal as alternatives to relicensing.

**Comments on the Studies Proposed in the PAD**

For both the Ripogenus and Penobscot Mills projects, the applicant proposes a Recreation Facility and Inventory Assessment study. Considering the complexities of the projects, impacts of the projects on more than 60 miles of the West Branch of the Penobscot River and its tributaries, as well as the nationally significant recreation resources in and adjacent to the project boundaries impacted by the projects, the scope of the applicant's proposed Recreation Facility Inventory and Condition Assessment is inadequate and must be significantly expanded. Therefore, AW and AMC are requesting a "Recreation Facility Inventory, Recreation Use and Needs Assessment, Aesthetics and Reservoir Surface Area Assessment Study", which is detailed in the study request section of this filing.

The applicant's proposal (PAD 6-19 and 6-21):

| | | | |
|---|---|---|---|
| Recreation and Land Management | Recreation Facility Inventory and Condition Assessment | Characterize existing Project recreational facilities and conditions | Potential/relevant study methods may include:<br>• Field inventory and documentation of existing Project recreational facilities.<br>• Desktop research and inventory of regional recreational facilities, opportunities, and management plans.<br>• Identify gaps, improvements, or use needs within the Project boundary. |

The applicant's proposed study will be inadequate in assessing the impacts of the projects on recreation. First, the PAD identifies the project boundaries, which at the Ripogenus project, includes Chesuncook Lake, the Ripogenus Bypass and project facilities at McKay Station only. According to the PAD, below McKay Station, the project boundary does not include the river corridor of the West Branch of the Penobscot though the Ripogenus Gorge, to Telos Road, and below to Ambajejus Lake. Since the project boundary does not include the river corridor below McKay Station, the applicant's proposed study would not assess recreational use in this corridor, popular for whitewater rafting, floating, and fishing enhanced by project operations. A field inventory should include an assessment of all formal recreation facilities, informal facilities in the project boundary being used by the public for recreation, and all recreational uses, areas and facilities that are outside of the project boundary but directly impacted by project operations, such as river access locations between McKay Station and Ambajejus Lake. Non-project recreation areas are inextricably linked to the projects' operations and must be studied, such as those used by whitewater boaters and fisherman downstream of McKay Station. This information cannot solely be obtained through a desktop analysis as proposed and must include a field inventory of non-project recreation areas, as well as user intercept surveys to assess satisfaction, demand, and projected future needs. Since whitewater paddlers are accessing the river corridor at McKay station, for example, within the project boundary and most often taking off the river outside of the project boundary after traveling downstream, it is necessary to assess the adequacy of recreational facilities on non-project lands to ensure that project recreation facilities can meet current and projected use

Further, the proposed study will inadequately address the relationship between recreation and project operations at the project reservoirs. It is necessary to map the relationship between reservoir surface area and reservoir levels at all the projects, and to understand how reservoir use and recreation is impacted by lake levels fluctuated by project operations. A field inventory and desktop analysis must include a use and needs assessment conducted at a variety of reservoir elevations, with user surveys conducted within the full range of reservoir elevations allowed under the current license and within project operational ranges.

Finally, the proposed study fails to address the impacts of the projects on the aesthetic values of the reservoirs, river reaches, and other natural areas impacted by project operations. This component must be included within the scope of the study to ensure the public's satisfaction with the aesthetic values impacted by the projects. A dedicated Aesthetic Resource Study is requested to specifically assess the impact of project facilities on the surrounding landscape.

## Study Requests

The following study requests are requested for the Ripogenus and Penobscot Mills hydroelectric projects. While these projects are separately licensed by FERC, the projects are owned and operated by the same licensee, are in proximity to one another on the same river, and are closely related operationally. As such, we file these study requests jointly for both projects and expect that the licensee will undertake a joint study plan covering the entire study area from the top of the Ripogenus impoundment to the bottom of the East Millinocket tailrace including Millinocket Stream, project storage areas, and bypassed reaches.

- **Study Request 1: Recreation Facility Inventory, Recreation Use and Needs Assessment, Aesthetics and Reservoir Surface Area Assessment Study**

*Goals and Objectives*
§5.9(b)(1)
The goals of the Recreation Facility Inventory, Recreation Use and Needs Assessment, Aesthetics and Reservoir Surface Area Assessment Study are to:

1. Obtain information about the condition of existing formal and informal recreation facilities and access to lands and waters from the top of the Ripogenus impoundment to the bottom of the East Millinocket tailrace including Millinocket Stream, project storage areas, and bypassed reaches; and existing recreation use, and demand at the project and non-project locations in this area;
2. Evaluate the adequacy of existing access to areas in and adjacent to project lands including impoundments and bypassed reaches in the project boundaries and on lands from the top of the Ripogenus impoundment to the bottom of the East Millinocket tailrace including Millinocket Stream, project storage areas, and bypassed reaches, including formal and informal access areas that are utilized for boating, angling, hiking, and other recreational use;
3. Conduct an assessment of the need to enhance recreation opportunities and access from the top of the Ripogenus impoundment to the bottom of the East Millinocket tailrace including Millinocket Stream, project storage areas, and bypassed reaches;

4. Determine the minimum acceptable and optimal aesthetic flow in the bypassed reaches in the in the Ripogeus and Penobscot Mills projects including the Ripogenus Upper Gorge Dryway and the Stone Dam Dryway, as well as in Millinocket Stream sufficient to protect aesthetic values; and,
5. Quantify and map the relationship between reservoir surface area and reservoir levels, and how those reservoir elevations relate to recreation; and,
6. Inform the development of a Recreation Management Plan for the implementation of any enhancement measures and long-term monitoring of recreation demand and adequacy of project and non-project facilities over the term of new licenses.

§5.9(b)(2)
Not applicable.

§5.9(b)(3)
Sections 4(e) and 10(a) of the Federal Power Act require the Commission to give equal consideration to all uses of the waterway on which a project is located, and what conditions should be placed on any license that may be issued. In making its license decision, the Commission must equally consider the environmental, recreational, fish and wildlife, aesthetics, and other non-developmental values of the project, as well as power and developmental values. Any license issued shall be best adapted to a comprehensive plan for improving or developing a waterway or waterways for all beneficial public uses. Recreation and aesthetics have been identified as legitimate project purposes by the Commission. The Ripogenus and Penobscot Mills Projects, including reservoirs, bypassed reaches, and riverine reaches below the projects, have the potential to offer recreational opportunities unique to the region, provided that sufficient flow and access are provided.

*Background and Existing Information*
§5.9(b)(4)
The PADs provide a general description of public recreation facilities, activities, and recreational use at the projects. However, the PAD provides no detailed information regarding the condition of existing facilities or type or location of various uses as would be indicated by detailed user surveys and field data. The PADs provide no project-specific information regarding visitor perceptions and identified needs at the projects and areas impacted by the projects. Information on current use and whether existing access to facilities in the area are meeting recreation demand would inform a decision on whether additional designated public access at and near the projects is necessary to meet existing and future recreation demand at the projects. Further, no information is provided in the PADs regarding the impact of project operations on aesthetic values in the bypassed reaches, in each of the developments. American Whitewater maintains a rivers database representing the most comprehensive listing of whitewater boating resources in the nation including the river reaches on the West Branch of the Penobscot River impacted by these developments. The PAD describes only some of the whitewater boating resources at and near the projects but fails to adequately describe the significantly diminished opportunities for water-based recreation above, at, and below the projects due to project operations.

*Project Nexus*
§5.9(b)(5)

The projects include multiple reservoirs, bypassed reaches, and riverine reaches within and below the project boundaries, which are inherently attractive recreation features. An analysis of existing recreation uses and access at and near the projects would help form the basis for determining the projects' impacts upon, and ability to enhance, public recreation access opportunities. Flow over the dams and in the bypass directly impact both recreation use and aesthetics. Also, an assessment of the current level of recreation use would provide information necessary to develop a Recreation Management Plan for efficient management of the recreational components of the project over the term of a new license.

*Proposed Methodology*
§5.8(b)(6)
1. Provide the methods and results of the investigation of the existing recreation facilities conditions.

2. The facility inventory will include characterization of the suitability of the bypassed and riverine reaches below each development for whitewater boating (e.g., gradient, length, character of potential flows), angling, swimming, and other recreational uses.

3. The use and needs assessment will include all recreation activity types known to occur or potentially occurring in the project area, on both project and non-project lands and waters impacted by project operations. Specific methods should include visitor observations; on-site visitor intercept surveys at formal and informal public recreation areas at the project reservoirs, bypassed reaches, tailraces, and riverine areas; and mail and/or internet surveys targeting unique stakeholder groups that may not be practically accessed through on-site surveys (e.g., adjacent residential landowners, residents of the counties in which the projects are located, hikers, whitewater boaters).

4. The needs assessment will include the demand for whitewater boating, angling, swimming, and other recreational uses in the project area, feasibility of providing additional public access at the project reservoir and riverine reaches (potential locations, type of facilities and access, and any associated costs), identifying visitor perceptions regarding the adequacy of recreation facilities, and access in the project area, and assessing future recreation demand and facility needs at and near the project under different modes of operation.

5. The aesthetic assessment will include a range of alternate spillages that should be videotaped and qualitatively analyzed, and a demonstration study should be arranged for direct observation of flows by a team for subjective grading. Use of drone UAS platforms would be of considerable use in determining areas that are usually accessible only from the water or through terrain management. A rating form is employed to provide a structure for the individual observations.

6. Assess visitor perceptions of the effects of project operations and management on recreation and recreation opportunities at and near the project (including fluctuating reservoir levels, minimum flow releases, and anticipated changes) over a new license term. Identify potential measures to alleviate any negative effects as well as to enhance existing recreation opportunities and access.

7. A Recreation Management Plan for the projects should be included in the license application and should include, at a minimum:

(1) a description of any proposed protection, mitigation, and enhancement measures, including: location of any proposed facilities and/or access areas (including description and figure depicting the relationship of any proposed facilities to the existing project boundaries), proposed ownership and management of any proposed facilities, associated capital, and operation and maintenance costs; and a timeline for implementation;
(2) a description of operation and management measures associated with project-related recreation access and facilities;
(3) a description of measures for future monitoring of recreation demand and adequacy of project-related facilities to meet this demand over the term of new licenses; and,
(4) the impact of climate change on future recreational use and periodic review and amendment to the Recreation Management Plan to meet changing demand and use over the term of the new license.

*Level of Effort and Cost*
§5.9(b)(7)
The estimated cost of the Recreation Facility Inventory, Recreation Use and Needs Assessment, Aesthetics and Reservoir Surface Area Assessment Study for the reach between the top of the Ripogenus impoundment to the bottom of the East Millinocket tailrace including Millinocket Stream, project storage areas, and bypassed reaches should be reasonable providing that these licensee coordinates with AW, AMC, other stakeholders and the impacted communities to develop and implement the study plan. One field season should be sufficient to collect the required data and prepare the report.

- **Study Request 2: Controlled-flow Whitewater Boating and Access Study**

*Goals and Objectives*
§5.9(b)(1)
The goals of the Controlled-flow Whitewater Boating and Access Study are to:

(a) assess the presence, quality, access needs, flow information needs, and preferred flow ranges for river-based boating resources in a stepwise manner;
(b) assess the effects of a range of optimal and acceptable flows on whitewater recreation opportunities for whitewater paddling in the following river reaches: 1) Ripogenis Dryway between Ripogenus Dam and McKay Station; 2) McKay Station to Debsconeag; 3) Stone Dam Dryway from Stone Dam to Shad Pond; and, 4) Millinocket Stream between Millinocket Lake Storage Dam and Shad Pond.
(c) assess the frequency, timing, duration and predictability of optimal and acceptable paddling flows under current, proposed, and alternative modes of operation;
(d) identify the need for, and define adequate put-in and take-out points that promote car-top boating, and also identify the need for additional or improvements to parking areas;
(e) identify the location, challenge, and other recreational attributes associated with specific rapids and other river features;

(f) assess the flow information needs of whitewater boating and the current and potential flow information distribution system.

§5.9(b)(2)
Not applicable.

§5.9(b)(3)
Sections 4(e) and 10(a) of the Federal Power Act require the Commission to give equal consideration to all uses of the waterway on which a project is located, and what conditions should be placed on any license that may be issued. In making its license decision, the Commission must equally consider the environmental, recreational, fish and wildlife, aesthetics, and other non-developmental values of the project, as well as power and developmental values. Any license issued shall be best adapted to a comprehensive plan for improving or developing a waterway or waterways for all beneficial public uses. Conducting the necessary studies and implementing measures to ensure public access to outdoor recreation is in the public interest. It is widely accepted that outdoor recreation has significant benefits to participants including health, well-being, and quality-of-life. Outdoor recreation also has proven economic benefits for communities located near recreational resources. FERC has concluded elsewhere that *"to fully evaluate the project's effect on whitewater recreation opportunities and to balance potential enhancement opportunities with their cost, a controlled-flow whitewater boating study is relevant to the Commission's public interest determination."* The reaches between Ripogenus Dam and Shad Pond, including bypassed reaches and the riverine reach along Millinocket Stream offers recreational opportunities unique to the region provided that sufficient flow and access are provided.

*Background and Existing Information*
§5.9(b)(4)
Whitewater boating is currently an existing use on the West Branch of the Penobscot River and Millinocket Stream. American Whitewater's national whitewater river inventory identifies these river reaches on the West Branch of the Penobscot River and Millinocket Stream as providing high quality whitewater boating opportunities. The PAD contains little information on whitewater boating use or the extent to which the Licensee's peaking operations and flow diversions impact on the availability of sufficient flows for whitewater boating in the vicinity of each of the projects undergoing relicensing.

*Project Nexus*
§5.9(b)(5)
Project operations at the Ripogenus Hydroelectric Project and the Penobscot Mills Hydroelectric Project directly impact whitewater boating opportunity at each development by diverting natural river flows into penstocks and powerhouses, inundating upstream rapids with impoundments, and dewatering natural river features that would otherwise be available for whitewater boating. While these impacts are partially mitigated under current operations, alternative modes of operation would enhance whitewater boating opportunity in and near the projects.

*Study Methodology*
§5.9(b)(6)

The study we request that the licensee for the Ripogenus and Penobscot Mills hydroelectric projects conduct a controlled-flow whitewater boating study on each of the four identified river reaches – Ripogenus Dryway, McKay Station, Stone Dam Dryway, and Millinocket Stream – following the standard methodology as described in Whittaker, et. al. (2005). This methodology is designed to assess the presence, quality, and preferred flow ranges for river-based boating resources in a stepwise manner. The process steps are generally 1) desktop analyses, 2) on-land feasibility assessment, 3) on-water single flow assessment, 4) on-water multiple flow assessment. We expect and request the full implementation of this methodology. Because the quality of the resource has not been fully analyzed with current metrics, we request that on-water multiple flow assessments be conducted.

We recognize that there is considerable existing information that will inform the study process with respect to the McKay Station reach; however, there is little existing information known about the two bypassed reaches and Millinocket Stream. During the Level 1 study phase, the licensees should compile existing information from literature, conduct individual interviews with organizations and individuals familiar with each aspect of the four river reaches, perform a hydrological analysis of flows on the West Branch of the Penobscot River and Millinocket Stream and project operations, and analyze of project operations under current and alternative modes of operation. Following the Whittaker study protocols, the licensee, in coordination with recreation stakeholders, should conduct a Level 2 study on those sections of the river where insufficient information is known to identify minimum acceptable and optimal flow levels and provide demonstration flows to an expert panel to identify appropriate flow ranges. Should the Level 2 study be insufficient to provide information necessary to fully evaluate the whitewater boating potential of the reach at various flow levels, an on-water multiple flow evaluation Level 3 study should be conducted in accordance with the protocols.

We will work with the licensee to document the known information regarding the river. We will provide volunteers and technical support for the studies as appropriate. We hope to work collaboratively with the licensee on this study. The whitewater boating study methodology we have requested has been used on dozens of other FERC regulated reaches.

*Level of Effort and Cost*
§5.9(b)(7)
We are willing to work with the licensee on the whitewater paddling controlled-flow study to keep costs reasonable and the quality of information high. The information that is already known about the reach below McKay Station can jump-start the study process and avoid duplicate effort. The consultants usually employ still image and video documentation, surveys of the boaters, a guided conversation among the boaters, and subsequently a written report. Given the collaborative approach sought by the paddling community, including in-kind contributions of time and expertise, a consultant should be able to complete this study on behalf of the licensee for a very reasonable cost.

- **Study Request 3: Aesthetics Resources Study**

*Goals and Objectives*
§5.9(b)(1)

The goals of the Aesthetics Resources Study are to:

(a) Inventory and baseline aesthetic resource conditions (e.g. visual and auditory);
(b) Determine if the projects have an adverse effect on a scenic vista, riverscape, or other noteworthy natural feature;
(c) Determine if the project degrades the existing character or quality of public views of the site and its surroundings;
(d) Determine if the project contributes substantial light or glare which would adversely affect night-time views in the area.
(e) Determine what the ambient noise levels are generated by the various plant operations and other uses of project lands.

§5.9(b)(2)
Not applicable.

§5.9(b)(3)
Sections 4(e) and 10(a) of the Federal Power Act require the Commission to give equal consideration to all uses of the waterway on which a project is located, and what conditions should be placed on any license that may be issued. In making its license decision, the Commission must equally consider the environmental, recreational, fish and wildlife, aesthetics, and other non-developmental values of the project, as well as power and developmental values. Any license issued shall be best adapted to a comprehensive plan for improving or developing a waterway or waterways for all beneficial public uses. Recreation and aesthetics have been identified as a legitimate project purpose by the Commission.

*Background and Existing Information*
§5.9(b)(4)
Across both the Ripogenus and Penobscot Mills hydroelectric projects, no aesthetic mitigation flows, or visual screening is required notwithstanding the presence of spectacular gorges, waterfalls, and geologic features throughout the project boundaries and surrounding landscape. The minimum flow at the Ripogenus Dryway varies from 100 cfs during the summer down to 12 cfs for the rest of the year leaving only a trickle in the river along the Upper Gorge Trail while the lower gorge below McKay flows with 1800 + cfs throughout the year, which likely impacts the aesthetic values of this reach. In the Millinocket Development, the Stone Dam Dryway remains completely dewatered below the dam except for 2 to 5 cfs leakage from the dam or other small tributary inflow also likely impacting the aesthetic values of this reach. The licensee's operations resulting in the lack of any meaningful flow in the Stone Dam Dryway has eliminated the aesthetic views of what was once Grand Falls but is now not so grand. At the Millinocket Lake Storage Development, the steady state flow of 60 cfs into Millinocket not only eliminates the benefits of naturally variable flows that restore aquatic habitat, but also diminishes the aesthetic views of the river by boaters paddling the reach. We seek a study to assess improvements in visual resources that multiple flow choices can provide.

Visual impacts and natural vegetative screening should be evaluated to mitigate the unnatural development in that area. Minimization of visual intrusion associated with the vertical tailrace walls and blasted cliff faces can be accomplished by masonry, painting and other mechanisms to

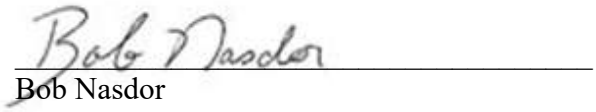
disguise the unnatural features of this part of the development. We seek a study that will assess the characteristics and severity of these elements of the facilities and earth tone painting, vegetation plantings and physical modification options that will reduce the visual intrusion these elements of the facilities represent. Similarly, the lack of water flow over the impoundment dams degrades the visual aesthetics in the bypassed reaches. We seek a study to assess improvements in visual resources that multiple flow choices can provide.

*Project Nexus*
§5.9(b)(5)
Project operations at the Ripogenus Hydroelctric Project and the Penobscot Mills Hydroelectric Project directly impact the aesthetics of the surrounding landscape as experienced by visitors. The Katahdin Region is widely known for its natural, recreational, and aesthetic characteristics. The six dams and related hydropower projects cause significant impacts on the aesthetic values of the river corridor and surrounding landscape, through both the diversion of water into conduits and through the introduction of a significant number and size of man-made structures directly and indirectly related to project operations.

All the projects feature structures and landscape disturbances that are egregious man-made intrusions upon what were once unspoiled natural riverscape vistas. Examples include Upper Gorge Hiking Trail and Grand Falls as well as the tailwater structures and equipment atop the blasted notch into the once spectacular cliffs McKay Station, the study we seek will explore a full range of options to mitigate the degradation of the natural scenic vistas occasioned by the equipment, structures and landscape disturbance associated with each project.

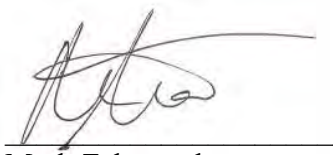
*Study Methodology*
§5.9(b)(6)

An aesthetic resource study will evaluate the impacts of the project facilities to visually sensitive areas, resources, and residential areas. A study methodology may be designed based on the visual classification systems that have been developed by the federal Bureau of Land Management[1] and U.S. Forest Service[2] and by some states to rank the scenic quality of various landscapes. Using these standards may be appropriate to quantify the potential visual impact of project operations on a given scenic, natural, and/or recreation area. Visual impacts on areas such as historic districts, traditional cultural properties, and places listed on, or eligible for listing on, the NRHP should also be addressed by the study. For all designated or sensitive scenic areas, a study should describe mitigation proposed to reduce visual impact. Mitigation may include planting shrubs and small trees for visual screening; removing or restoring project facilities in disrepair; removing and implementing management plans related to debris and trash; evaluating the need for audible mitigation and light pollution mitigation as appropriate. Additional mitigation measures may be recommended such as painting the facility with colors that would harmonize with the landscape, building facades consistent with natural features or buildings in the area, or effectively restoring the landscape, including screening the facility with shrubs and trees. Part (e) of section 380.15 (siting and maintenance requirements) provides additional information about avoiding and minimizing impacts on visually sensitive resources.



[1] https://www.blm.gov/programs/recreation/recreation-programs/visual-resource-management
[2] https://blmwyomingvisual.anl.gov/vr-inventory/usfs/

*Level of Effort and Cost*
§5.9(b)(7)
We are willing to work with the licensee on the aesthetic resource study to keep costs reasonable and the quality of information high. The information that is already known and documented can help serve as a baseline inventory, such as existing unused project facilities, project structures in disrepair, audible impacts, and aesthetic impacts of dewatered river reaches. Paddlers and our members will offer photographs, key person interviews, and may also suggest avoidance, minimization, and mitigation elements. Given the collaborative approach sought by the paddling community, including in-kind contributions of time and expertise, a consultant should be able to complete this study on behalf of the licensee for a very reasonable cost.



## Conclusion

We respectfully request that the licensees for the Ripogenus Hydroelectric Project and the Penobscot Mills Hydroelectric Project complete the above described (1) Recreation Facility Inventory, Recreation Use and Needs Assessment, Aesthetics and Reservoir Surface Area Assessment Study, (2) Controlled-flow Whitewater Boating and Access Study, and, (3) Aesthetic Resources Study, in order to provide FERC with sufficient information to complete its NEPA analysis of project impacts to determine appropriate license conditions that are protective of recreation values and mitigate project impacts. Thank you for considering these comments.

Respectfully submitted this 8th day of October, 2021

## CERTIFICATE OF SERVICE

I hereby certify that on this day I have caused to be served electronically a copy of the foregoing Comments and Study Requests of AW & AMC on all parties listed on the official service list compiled by FERC in this proceeding in accordance with the applicable FERC regulations.

Dated at 8, October, 2021

Mark Zakutansky

Beckham M Bayreuther, Caratunk, ME.
My name is Beckham Bayreuther. I am a young whitewater kayaker and fisherman, and I get to enjoy some of Maine's greatest outdoor experiences because of it. The Dryway on the West Branch of the Penobscot River is one of those many great Maine adventures that few people get to enjoy. I as well as many other Whitewater/fishing enthusiasts would like to request a flow study on the Dryway, Millinocket Stream, and the Backbend to determine navigable water levels for the purposes of recreational/commercial boating and to judge flow rates for increased fish habitat. The goal of the requested study is to have a better understanding of minimum/ideal flows for kayaking and rafting as well as fish habitats. This study should have the objective of obtaining a minimum CFS required for kayaking and rafting as well as to obtain the minimum CFS required for kayaking and rafting. These flows should both accommodate all experience levels of whitewater boating as well as increase fish habitat.
The Dryway section of the Penobscot is just above the commercial rafting put-in (McKay Station) and is a section of the river where the water has been diverted from Ripogenus Dam to Mckay Station. This section is a special section of whitewater that is seldomly run because of low water levels. By finding flows suitable for whitewater boating it would lengthen the class IV/V section of the Penobscot by almost 2 miles. The requested study would also create information on this section, in terms of difficulty and navigability
This study should be done by scheduling a day or days in which Brookfield Releases 300,500,1000,1500,2000,3000cfs out of Ripogenus Dam. This would allow for kayakers, rafters, and fishermen to assess the different flows to find a minimum and ideal flow. After there should be a meeting and survey conducted to organize results. This study should find flows that maintain downstream conditions.

Christopher Howe, kingfield, ME.
I Christopher Howe manage a raft company in Millinocket and have been a registered Maine Whitewater Guide for 13 years, and own a home in Kingfield, Maine.

I have enjoyed paddling the whitewater of Millinocket Stream on many occasions. probably around 20-30 times over the last 12 years from flow levels of 400cfs to about 1200cfs.

There are currently no scheduled releases from Millinocket Lake Dam.

The section of river I am referring is from Millinocket Lake Dam down to the snowmobile bridge just off the Staceyville road.

This section of whitewater currently only runs unscheduled in the spring, generally in May and sometimes later in the year with significant rainfall.

I have taken many friends and coworkers on Millinocket Stream to introduce them to whitewater kayaking and canoeing.

The rapids of Millinocket Stream, Class II create one of the best learning environments for whitewater boating I have ever seen. The rapids are small and short with nice long pools at the bottom.

Having any scheduled releases on Millinocket Stream will create a great introduction to whitewater for folks in the region. which is already a prevalent form of recreation in Millinocket with the West Branch of the Penobscot.

Having scheduled releases for the purpose of whitewater boating on Millinocket Stream can give the town of Millinocket yet another form of recreation to help draw people to the town as a place to live.

Having a scheduled release on Millinocket Stream could also open up the the possibility of holding a Canoe Race. Canoe races all over the state bring significant tourism and economic impact to the local region and draw people to visit the town. The venue of Millinocket Stream for a canoe race would be extraordinary and would easily rival the Kenduskeag Canoe Races and Soudabscook Canoe Races. A Millinocket Stream Canoe Race would significantly add to the the already vibrant canoe racing circuit in the state of Maine, and amongst racers the stream would become known for its consistent rapids.

Having scheduled releases from Millinocket Lake dam would offer a tremendous opportunity for Commercial Whitewater Rafting Outfitters to expand their trip offerings. Outfitters could run clients from the Millinocket Lake Dam in inflatable kayaks also known as Duckies. This can be a incredible experience and gateway to whitewater rafting clients to experience the river in their own craft under their own control. As a whitewater guide for 13 years, Kids and Families would absolutely love this trip if it were offered.

Local public schools currently use Millinocket Stream as part of a Outdoor Ed/Recreation program to get youth out on the river.

Currently they are limited to only paddling the very lower part of the stream because of low water conditions upstream were the river is unnavigable.

I request a flow study to assess river conditions downstream of Millinocket Lake Dam to determine minimal and ideal flow rates for the purpose of whitewater boating

Goals:
A) to find minimum and ideal flows for recreational rafting, kayaking, and canoeing.
B) To obtain data about minimum and ideal flows needed to increase fish habitat.

Objectives:
Determine any congruencies between recreational boating and increased fish habitat.
Obtain minimum CFS level required for kayak, canoe, and raft passage.
Obtain an ideal CFS level for kayak, canoe, and raft passage.
Obtain an ideal flow for increased fish habitat.

Methodology:
A)Schedule a day or days where Brookfield Releases 200, 300, 400, 500,1000cfs from Millinocket Lake Dam.
B) Schedule kayakers, rafters, canoers, and biologists to be available to assess all flows and water temperatures.
C) Have participants fill out surveys about observed river conditions.
E) Have a team compile the data and make a report to present to FERC on the flow study findings.

Anticipated Outcomes:
Find a flow that Brookfield, kayakers, canoer's, and fishermen can all agree on to make this extraordinary beginner whitewater run available to the public.

Conclusion:

I would like to see Several Scheduled releases through out the summer that could economically benefit the town by holding a Canoe Race, create additional income for rafting outfitters, provide the Katahdin Region youth with a great river to get into whitewater boating, and also bolstering the Katahdin Regions recreational benefits and offerings to help draw people to move to the town.

**Reference: Staff Comments on the Pre-Application Document and Preliminary Study Proposals for the Ripogenus Hydroelectric Project and the Penobscot Mills Hydroelectric Project**

Dear Mr. Dorman:

We have reviewed the Pre-Application Document (PAD) for the Ripogenus Hydroelectric Project No. 2572-133 (Ripogenus Project) and the Penobscot Mills Hydroelectric Project No. 2458-247 (Penobscot Mills Project), filed on June 11, 2021, and conducted scoping meetings and participated in the environmental site review for the projects on September 9, 2021.

Based on staff's review of the PAD, scoping meetings, and site review, we need additional information and clarification on the material presented in the PAD. Unless otherwise indicated in the specific request, the information requested (*see* attached Schedule A) should be filed with the proposed study plan on, or before, November 23, 2021. If the requested information is not readily available, the proposed study plan should discuss Great Lakes Hydro America, LLC's plans for gathering the information prior to filing the final license application. In addition, if the requested information causes another part of the PAD to be inaccurate, that part must be revised and provided as well. Please be aware that further requests for additional information may be sent to you at any time before the Commission takes final action on your application. We also provide comments on the preliminary study proposals in Schedule B.

If you have any questions, please contact Allan Creamer at (202) 502-8365, or allan.creamer@ferc.gov.

Sincerely,

Stephen Bowler

Stephen Bowler, Chief
South Branch
Division of Hydropower Licensing

Schedule B

**SCHEDULE A**
**ADDITIONAL INFORMATION REQUESTS**

*General*

1. The Preliminary Application Document (PAD) provides a summary of the studies performed during the previous relicensing. During the September 9, 2021, scoping meetings, stakeholders expressed concern regarding access to reports and information. On September 24, 2021, Great Lakes Hydro America, LLC (GLHA) filed the 1991 license applications for the Ripogenus Hydroelectric Project No. 2572-133 (Ripogenus Project) and the Penobscot Mills Hydroelectric Project No. 2458-247 (Penobscot Mills Project), along with supporting study reports and post-license monitoring reports. However, there are additional references in the PAD that were not included in GLHA's September 24 filing. Please include with the Proposed Study Plan (PSP) copies of the following documents/information:

    (a) Maine Rivers Fish Assemblage Assessment: Interim Report, Assessment: Interim Report II Penobscot River & Tributaries: 2004. (Yoder *et. al*, 2008);
    (b) Maine Rivers Fish Assemblage Assessment: Interim Report II (Midwest Biodiversity Institute & Center for Applied Bioassessment and Criteria (MBI), 2005);
    (c) MDIFW unpublished sampling data from 2017 and 2018, as cited in a footnote on p. 5-122;
    (d) Swartz (2007), as referenced on page 5-134 of the PAD;
    (e) Recreational Activities in the Ripogenus Project Survey, as referenced on page 5-213 of the PAD; and
    (f) Shoreline Buffer Zone Management Plans, including any amendments to the plans, for the Ripogenus Project and Penobscot Mills Project.

*Project Description*

2. The PAD, in sections 4.3.1, *Ripogenus Project*, and 4.3.2, *Penobscot Mills Project*, describes the steel trash rack structures at the Millinocket Lake Storage Development's pumping station and at the projects' powerhouse intakes. The PAD indicates that the trash racks have clear bar spacings varying from 1 inch to 2-7/8 inches. No other design specifications are provided. To assist us in our review of potential fish entrainment and impingement at the projects, please include in the license application: (a) the overall dimensions (including bar spacing) of each trash rack panel protecting the project intakes; and (b) estimates of the approach velocity and through-the-rack velocity for the trash racks, along with the calculations and/or methods used to develop the estimates. This information is required by sections 4.51(b)(1) and 5.18(a)(5)(iii) of the Commission's application regulations. If any of

this information is not available, such information should be obtained as part of GLHA's proposed studies.

3. The Penobscot Mills Project was originally licensed in 1996 with 70.6 MW of installed capacity. The PAD, in section 4.3.2, *Penobscot Mills Project*, states the authorized installed capacity is 67.875 MW. Please account for the lower installed capacity reported in the PAD, which may be due to inoperable turbines at the Millinocket Development. For any turbines which are inoperable, please describe when the turbines were shut down, and the necessary repairs needed to refurbish the turbines. Your application should also include a summary of modifications to any of the project turbines which have occurred since filing of the March 31, 2000 Exhibit A, which describes the project facilities.

   Exhibit A, filed on March 31, 2000, identifies a 5-mile-long transmission line extending from the 40 hertz (Hz) Dolby substation to the 40 Hz Substation No. 1 located at the Millinocket Mill. Your comments on Scoping Document 1, filed October 5, 2021, state that this transmission line is currently out of service. Please describe when and why this line was shut down, and the status of plans to return this line to service. Your application should also include a summary of any modifications to any of the project transmission lines which have occurred since filing of the March 31, 2000 Exhibit A, which describes the project facilities.

*Project Operation*

4. Tables 4.3-1, 4.3-4, 4.3-6, 4.3-8, and 4.3-10 of the PAD provide the hydraulic capacities (in cubic feet per second or cfs) for the turbines associated with the Ripogenus and Penobscot Mills Projects. It is not clear if the hydraulic capacity provided is rated capacity or some other capacity (e.g., minimum, or maximum hydraulic capacity). To clarify the hydraulic capacities shown in the tables and the operating capabilities of the project's units, please revise the tables to include the minimum, rated, and maximum hydraulic capacities of each unit and file the revised tables with the PSP.

5. Section 4.4, *Project Operations*, of the PAD indicates that the Ripogenus and Penobscot Mills Projects are operating as a combined system. Specifically, the PAD states that the Ripogenus Project and two developments associated with the Penobscot Mills Project (Millinocket Lake Storage Development and North Twin Development) are operated as storage and release facilities. Three other developments associated with the Penobscot Mills Project (i.e., Millinocket, Dolby, and East Millinocket) are operated in a run-of-river mode (or run-of-release). During the September 9, 2021 daytime scoping meeting, NMFS representatives characterized the operations of the two developments as daily peaking.

Detailed operations data is needed to clarify how the projects are operated on a daily basis. Therefore, please include, as an appendix to the Proposed Study Plan, 10 years of operations data (in excel format) for each project, or each individual development, in the case of the Penobscot Mills Project, including: (1) daily impoundment elevations; and (2) daily outflows (minimum, maximum, and average discharges). The data for each project/development should be presented in separate tabs of the excel spreadsheet. In addition, in order to characterize any changes in the hydrologic conditions in the West Branch, please provide, in the license application, the average annual flow at the Penobscot Mills Project for the period of record of 1970 through present.

*Water Resources and Water Quality*

6. Section 5.3.4, *Existing and Proposed Uses of Project Waters*, of the PAD refers to a Water Use Plan that was developed during the prior relicensing based on prioritized water uses and operations modeling. This Water Use Plan was used as the basis for the operational requirements included in the projects' 1996 licenses. To assist us in reviewing the water management issues at the two projects, please provide: (1) a copy of the current Water Use Plan, including any amendments made to the original plan; and (2) all of the 10-year reports documenting the effectiveness of the Water Use Plan, as required by Article 403 of the 1996 Ripogenus Project license.

7. The Water Use Plan described above was based on a Water Use Model developed in 1996 to evaluate various flow proposals. If you plan on using this Water Use Model to support your licensing proposal, please provide: (1) any report documenting the model development and the results of any modeling done to support development of the Water Use Plan; and (2) a quantitative analysis showing the hydrology in the project area has not changed since 1996 when the model was developed. This analysis may be accomplished by comparing hydrographs for the project area. The Water Use Model used a hydrologic record and developed flow duration curves for a 15-year period between 1976 and 1990. Similar information can be prepared and analyzed for the most recent 15-year period.

8. Appendix D of the PAD provides monthly and annual flow duration curves for the outflows at the Ripogenus and Penobscot Mills Projects for the period 2016 through 2020. So that we may accurately read the numbers defining the curve, in addition to the curves, please provide this information in tabular format in a Microsoft Excel file.

*Fisheries and Aquatic Resources*

9. Section 4.3.1, *Existing Project Facilities-Ripogenus Project*, of the PAD (on page 4-14), states that the invert elevation of the Ripogenus Project intake is 898.09 feet "USGS datum," which is 43.5 feet below the normal full-pool elevation of the Ripogenus impoundment. To assist us in reviewing water quality issues in the West Branch of the Penobscot River downstream from Ripogenus Dam, please describe: (1) the relationship between the intake's invert elevation and the typical depth at which thermal and dissolved oxygen (DO) stratification occurs in the Ripogenus impoundment; (2) the quality of water (i.e., DO and water temperature) discharged from McKay Station; and (3) the mechanism and point of release for water released from Ripogenus Dam to the Upper Gorge. If any of this information is not available, such information should be obtained as part of the PSP.

*Wildlife, Botanical Resources, and Threatened and Endangered Species*

10. Section 5.6(d)(3)(vi) of the Commission's regulations require that the PAD include estimates of acreage for each type of wetland, riparian, and littoral habitat, including variability in such availability as a function of storage at a project that is not operated in a run-of-river mode. We need this information to assess the potential impacts of project-related water level fluctuations on wetlands, littoral and riparian vegetation, and wildlife. In the PAD, wetland habitats in the vicinity of the projects are presented in figure 5.6-1 through figure 5.6-6, and table 5.6-1 includes a summary of wetland habitats occurring within the approximate boundaries of the projects. However, the PAD does not discuss the variability in these habitats associated with project operation. Thus, if available, please include in the license application, estimated variability (in acres) of each type of wetland, riparian, and littoral habitat as a function of storage at the projects. If this information is not currently available, please include collection of the data as part of your PSP.

11. Figures 5.6-1 (sheets 8 through 10) and 5.6-5 in the PAD include maps of the Ripogenus Project and Penobscot Mills Project transmission line corridors. To assist in our review of potential effects of transmission corridor maintenance on wetlands, please provide, in the license application, a breakdown of the wetland acreage provided in table 5.6-1 that includes the acreages by the wetland types occurring in the transmission line corridors for each project. Also, the wetland maps of the transmission line corridors are difficult to review due to the small scale (e.g., sheets 8 through 10 in Figure 5.6.1). When filing your license application, please provide larger scale wetland maps of the transmission line corridors at the projects that include wetlands in the vicinity of the corridor as well as those directly within the corridor.

12. Table 5.5-3 in the PAD provides a list of numeric identifiers and quality rankings of mapped inland waterfowl and wading bird habitats that are located within the approximate boundaries of the projects. However, no maps were provided. To facilitate our review of the potential effects of the projects on waterfowl and wading bird habitats, please include in the license application a map, or maps, indicating the location of these areas relative to the project boundaries, and include the acreage associated with each type of habitat in tabular format.

13. The license application is required to include information regarding the potential effects of the current and proposed project operation, maintenance, and project-related recreation on project resources, including botanical and wildlife resources; wetlands, riparian, and littoral habitat; and rare, threatened, and endangered species and habitats (*see* sections 5.16(b)(3) and 5.18(b)(5)(ii)(B)). Commission staff also intend to evaluate any Endangered Species Act candidate species potentially occurring in the project areas. As noted on page 5-197 of the PAD, in table 5.7-1, and Appendix F, the project areas include diverse upland and wetland habitat associated with the shoreline of the West Branch, and the shorelines of the impoundments within the project boundaries. Additionally, there are about 36 miles of transmission line corridors within the project boundaries. Therefore, with the license application, please include an evaluation of the projects' effects on the aforementioned environmental resources. Also, to assist staff in assessing the potential occurrence of federally-listed species or candidate species within the vicinity of the projects, please file the U.S. Fish and Wildlife Service Information for Planning and Consultation (iPaC) database reports referenced in the PAD, and the GIS data layers for the project boundaries used to generate the iPaC reports.

14. The PAD, in Figure 5.5-1, depicts a map of the Back Channel showing the Wildlife Management Area (WMA) and associated enhancements. The WMA comprises about 2,300 acres of land adjacent to the Back Channel downstream from Stone Dam and Quakish Lake. To facilitate our analysis of potential project effects on the resources of the WMA, please provide a breakdown of the following in the license application: (1) wetland types and acreage for each of the management blocks illustrated in figure 5.5-1; (2) the total acreage for each of the management blocks; (3) a description of the forest type, dates, and acreage of the timber harvest completed in Management Block 3, and (4) a description of the forest type, estimated dates, and acreage of the timber harvest proposed in Management Block 4. Please also include a revised figure 5.5.1 with the National Wetlands Inventory (NWI) wetlands shown in figure 5.6.4 of the PAD.

*Recreation and Land Use*

15. The PAD, in section 5.8.2, *Existing Project Recreation Facilities and Opportunities*, indicates that there are six project recreation facilities at the Ripogenus Project: Caribou Lake Put-In, Chesuncook Dam Point Boat Launch, Chesuncook Lake Remote Campsites, Umbazooksus Stream Campsites, Upper Gorge Trail, and McKay Station Rafting Put-In Site. The same section of the PAD lists six project recreation boat launch facilities at the Penobscot Mills Project: Millinocket Lake, Ambajejus Lake, South Twin Lake (Partridge Cove), Green Bridge, Dead Man's Curve, and Dolby Pond (Flowage). No schematic drawings (only photographs) were included for the facilities. To facilitate our review of recreation resources at the projects, please include in the license application a map or drawing of each facility showing all amenities to scale, including parking areas, in relation to the project boundary.

16. The PAD, in section 5.8, *Recreation and Land Management*, lists several non-project recreation facilities at the Ripogenus and Penobscot Mills Projects that are located within the project boundaries. To facilitate our review of all the existing recreation facilities at the projects, please identify these facilities on a map (or maps) with respect to the project boundaries and include the map(s) with the license application.

# SCHEDULE B
# COMMENTS ON PRELIMINARY STUDY PROPOSAL

## PRELIMINARY STUDY PROPOSAL COMMENTS

*General*

1. In section 6.2, *Proposed Studies and Information Gathering Associated with Identified Issues*, of the Preliminary Application Document (PAD), Great Lakes Hydro America, LLC (GLHA) states that a significant body of information exists for the Ripogenus Hydroelectric Project No. 2572-133 (Ripogenus Project) and the Penobscot Mills Hydroelectric Project No. 2458-247 (Penobscot Mills Project). GLHA maintains that a full suite of new studies is not needed and that the information on which the existing licenses are based is sound and should be relied upon in these relicensing proceedings. However, many of the referenced studies are 30 years old and may not reflect current conditions. To ensure that the current relicensing of the two projects is based on current information, GLHA should demonstrate, with supporting information, that the results of the past studies remain valid today.

*Water Quality*

2. During the September 9, 2021, daytime scoping meeting, questions were raised regarding what information is available to describe the water temperature released from Ripogenus Dam and McKay Station and the effect of those temperatures on the West Branch of the Penobscot River downstream from the project. It is not clear from GLHA's response what, if any, data exists to address this question. In order for us to evaluate the temperature effects associated with water released from the Ripogenus Project, please ensure that your proposed Water Quality Study Plan includes methodologies to collect information in sufficient detail to: (a) accurately describe existing water temperature and dissolved oxygen in the Upper Gorge and the West Branch of the Penobscot River downstream from McKay Station; and (b) assess potential project-related effects on water quality in the river.

*Recreation and Land Use*

3. In section 6.0 of the PAD, the proposal for recreation facility inventories states that Great Lakes Hydro will inventory and describe the project recreation facilities and amenities. During the scoping meeting, and in submitted comments, concerns were raised about access to recreation facilities under low water conditions. Additionally, in section 5.10 of the PAD, erosion issues at recreation facilities were discussed. To facilitate our review of the status of recreation access, please include in an inventory

of the general condition of the project recreation facilities, and documentation of any specific erosion issues or low-water use limitations affecting recreation at the facilities.

Additionally, section 6.0 states that updated recreation plans will be included as part of the license application. Please ensure that maintenance procedures for the facilities are included in the plans.

Jacob Risch, MADISON, NH.
To Whom it may concern,

My name is Jake Risch, I am a co-owner of the Sawyer River Group, LLC a swiftwater rescue training company that teaches courses on the West Branch of the Penobscot River and a founding member and Vice President of the non-profit White Mountain Swiftwater Rescue Team in New Hampshire. I grew up canoeing on the lakes and rivers of the North Maine Woods and have been paddling Class V whitewater for more than 20 years. I have been a registered Maine Whitewater Rafting Guide and have explored rivers in 15 countries on four continents, including a 7-week expedition from the source of the Amazon in Peru, first descents in Turkey and Indonesia and expeditions to the remote corners of the Himalaya in Nepal. Through the Sawyer River Group, my business partner and I have imparted safety and rescue skills to hundreds of river users and first responders in Maine and New Hampshire.

Additionally, I am an event organizer. I am the race director for the Tuckerman Inferno Penthathalon adventure race on Mount Washington and the Smalls to the Wall kayak steep creek race on the Sandy River in Sandy River Plantation, Maine. I organize safety for the Maine Whitewater Championships on the Kennebec and West Branch of the Penobscot. I have paddled the Rippogenous Gorge dryway section at numerous flows from 500 cfs up through 5,000 cfs.

The dewatered section of the Rippogenous Gorge between Rippogenous Dam and McCay Station (or “dryway”) is a World Class whitewater run. This run provides a “Big Water” experience comparable to rivers in the Himalayas, Andes, and the Rockies. A scheduled release through the dryway would attract whitewater paddlers from around the northeast and eastern Canada. A dryway release would be an event around which a whitewater festival similar to the festivals on the Moose and Beaver (in upstate NY), Deerfield (in Western Mass), and Gauley (in West Virginia) rivers could be organized bringing significant economic stimulus to the Millinocket region. The run from the Rippogenous Dam through the dryway combined with the existing Rippogenous Gorge to Cribworks section ending at Big Eddy would be the premier scheduled Class IV/V run in New England and provide ample incentive for whitewater enthusiasts to make the trek to northern Maine.

From a difficulty/navigability standpoint, I would consider the run a Class IV or V run depending on the flow and no more difficult than other regularly and commercially-run dam release rivers around the country.

There is safe access to the section using an anglers trail on river left departing from the parking on the north side of Rippogenous Dam.

I formally request a flow study to determine the optimal flow to provide recreational opportunities for the widest range of whitewater paddlers and validate the feasibility of access on the river left bank.

Thank you for your consideration.
Jake Risch

Miles Puleio, Saco, ME.
My name is Miles Puleio. I have lived, worked, and recreated on the West Branch of the Penobscot River since 2011. I am a Class V kayaker and have paddled the Mckay to Big Eddy section thousands of times. I am also a fly fisherman and on average I fish 50 plus days a year on the Penobscot River.

Over these years the flows released have been drastically different. The flow changes I have witnessed on a day to day basis are fluctuating and inconsistent. A digital online gauge to find the hourly flow data would be a huge help for most recreational users. Fly fisherman and guides trying to drift the section of river below the Big Eddy to the above Big A find the takeout difficult to manage at a flow below 1700 CFS.

Peaking water flows not only effect users but more importantly the vital aquatic life in the river. Smelt are no longer abundant in this section of river, once years ago I am told by "old timers" the river was so filled with them, the shore of the river would have hundreds washed up. Now we see none washed up on the banks. The Caddis hatches are less abundant. Now maybe seeing only a few evenings during a season when Caddis cloud the sky. It is our responsibility to ensure this waterway be properly managed with the food source of the fish as top concern.
The average size salmon in my experience is no longer a 18"-20" fish. Fisherman are now reporting average fish at 12 - 14" inch salmon. A trophy fish is now the 18-20" range.

The Upper gorge Dryway section of river is an incredible stretch of whitewater. A release on the dryway section would be a huge recreational draw. A scheduled release on the dryway could lead to the next greatest river festival event happening in the Northeast. This could help to stimulate the local economy. Releasing cold water from deep gates could help cool the temperature of the river, creating a more inhabitable temperature for the fish. When the Dry way is running a certain flow and Mckay station is producing power at a certain flow a recreational play feature is created just up stream of the Hydro station at the bottom of the Dry Way. This wave is referred to in the kayaking community as the "wave that never was" due to its creation only occurring at very specific correlation of these two flows. It is my request that a flow study be done to determine what this ideal flow is to create this world class feature.
Thank you for the opportunity to comment.

Miles Puleio

Michael Smith, Millinocket, ME.
As a recreational paddler and professional outdoor educator living in Maine's Katahdin Region, I regularly paddle on the "Dryway" of West Branch of the Penobscot, as well as Millinocket Stream. The reaches in question in the Ripogenus Hydrologic Project (P-2572) and Penobscot Mills Project (P-2458) are exceptional in their natural beauty and recreation potential. As a member of American Whitewater, I am in concurrence with their comments and study request for these projects.

In particular I want to emphasize the need to further study flows on Millinocket Stream between Millinocket Lake and Shad Pond. This reach has the potential to serve as an incredible educational and recreational asset to the community and economy of Millinocket, and is a critical component in maintaining local fish and wildlife habitat. It's imperative that we study flows on this section so as to better manage water for recreational and environmental benefit.

Thank you for the opportunity to comment.

October 8, 2021

Ms. Kimberly D. Bose, Secretary
Federal Energy Regulatory Division
888 First Street, N.E.
Washington, D.C. 20426

**RE: Comment on PAD and Study Requests, Ripogenus Project (FERC No. 2572) and Penobscot Mills Project (FERC No. 2458)**

Dear Secretary Bose,

On June 11, 2021, Great Lakes Hydro America, LLC (GLHA), a subsidiary of Brookfield Renewable, submitted Notices of Intent (NOIs) to file an application for new licenses and a Pre-Application Document (PAD) for the Ripogenus Hydroelectric Project (FERC No. 2572) and the Penobscot Mills Hydroelectric Project (FERC No. 2458)(the Projects). Subsequently, FERC issued its Notice of Intent to File License Applications, Filing of Pre-Application Document, Commencement of Pre-Filing Process, and Scoping; Request for Comments on the PAD and Scoping Document, and Identification of Issues and Associated Study Requests for the Projects on August 10, 2021. The Projects are located on the West Branch of the Penobscot River and on Millinocket Stream in Piscataquis and Penobscot Counties, Maine.

The Bureau of Parks and Lands (BPL) is a division of the Maine Department of Agriculture, Conservation and Forestry (MDACF), a cabinet level agency of the State of Maine. As authorized under Section 10 of the Federal Power Act, BPL reviews hydropower projects and provides recommendation to licensees with a focus on the adequacy of existing public recreation facilities and access to meet public needs, the adequacy of flow releases to provide for downstream boating opportunities, and the effect, if any, on public lands and private lands if available for public recreation.

Based on these responsibilities we have prepared the following comments on the PAD and Study Requests:

**PAD Section 5.8: Recreation and Land Management**

5.8.2.1 Ripogenus Project, Project Recreation Sites

Project recreation sites are defined on page 5-205 as "those that have been approved by FERC, are located within the Project boundary, and are managed pursuant to the FERC license". Table 5.8-1 on page 5-206 includes "10 campsites at various locations around Chesuncook Lake" and "managed by Penobscot River Corridor" (PRC) among the Project recreation sites listed, but does not mention Gero Island specifically. The text on page 5-210 describing the Project recreation sites includes "10 remote campsites on Chesuncook Lake...located around Chesuncook Lake and on Gero Island…managed by the PRC."

BPL Comments

There are 14 campsites on Chesuncook Lake managed by the PRC; four of the sites are on Gero Island, as shown on Figure 5.8-1 (a reproduction of a regional map produced by BPL). Based on the Project boundary as shown on Figure 4.2-2 and the Exhibit G drawing provided in Appendix C, it appears that at least one of the Gero Island campsites (campsite #4, a group tent site) and possibly another site (campsite #3, a lean-to site) may be within Recreation Area No. 1, shown on both of those sources, and therefore within the Project boundary. However, precise boundary coordinates for Recreation Area No. 1 are not provided, so we are not able to confirm this. The following latitude/longitude coordinates are provided for reference:

| Site | Lat. | Long. |
|---|---|---|
| Campsite 3 | 46.060743 | -69.388105 |
| Campsite 4 | 46.055033 | -69.379735 |

If one or both of these campsites are indeed within the Project boundary, they should be added to the list of FERC-approved Project recreation sites and treated as such in the Integrated Licensing Process (ILP).

Relatedly, it should be made more evident in the ILP that Recreation Areas No. 1, 2 and 3 as shown on Figure 4.2-2 and the Exhibit G drawing are within the Project boundary. These areas are not mentioned in the PAD until section 5.8.7 Existing Shoreline Buffer Zones within the Project Boundary, where on page 5-242 they are described as reserved for potential future recreation use but currently undeveloped. As noted above, Recreation Area No. 1 may have at least one PRC campsite and, if so, cannot be accurately characterized as undeveloped.

As a final point of clarification, the 10 Chesuncook Lake Remote Campsites managed by PRC, as listed in Table 5.8-1, includes five locations with one tent site each as well as four locations with two or three tent sites each and one location with two group tent sites; in total, these locations provide 16 individual and group tent sites. The four Gero Island campsites include a tent and lean-to site (2 total), a tent site, a lean-to site, and a group tent site (five sites in total). All of these are depicted on Figure 5.8-1.

5.8.2.1 Ripogenus Project, Project Recreation Sites

The 2008 Recreation Facility Report for the Ripogenus and Penobscot Mills Projects (GLHA 2009, as referenced in the PAD) submitted to FERC lists the Caribou Lake facility as an informal boat launch and Umbazooksus Stream as a public boat launch. (The recreation facilities table in

the above report was reproduced from the Final Environmental Statement prepared by FERC for the previous relicensing of the Projects (FERC 1996, as referenced in the PAD)). However, Table 5.8-1 on page 5-206 lists Caribou Lake Put-in as a formal FERC-approved recreation site. The boat launch at Umbazooksus Stream (paired with the Umbazooksus Stream West campsite, as shown on Figure 5.8-1) is not listed, nor is it included on Figure 5.8-3 depicting FERC-approved Project recreation sites at the Ripogenus Project.

BPL Comments
The Bureau requests clarification as to the status of the Caribou Lake Put-in, and that the Umbazooksus Stream boat launch be added to the FERC-approved recreation sites for the ILP, or an explanation why this should not be done.

5.8.2.1 Ripogenus Project, Non-project Recreation Sites
On page 5-214, the document describes Gero Island as "a non-project 3,000-acre island."

BPL Comments
As we have stated above, based on the Project boundary as shown on Figure 4.2-2 and the Exhibit G drawing provided in Appendix C, Recreation Area No. 1 on Gero Island, shown on both of those sources, is within the Project boundary. Therefore, it is inaccurate to describe the entire island as non-project. Also, we wish to again note the non-project campsites on Gero Island managed by the PRC (the number of which are project/non-project to be determined, as requested above), which are not mentioned in this section of the PAD. Lastly, based on BPL data, Gero Island is 3,180 acres in area.

5.8.2.2 Penobscot Mills Project, Project Recreation Sites
The 2008 Recreation Facility Report for the Ripogenus and Penobscot Mills Projects (GLHA 2009, as referenced in the PAD) submitted to FERC lists the Millinocket Dam facility as a public boat launch. (The recreation facilities table in the above report was reproduced from the Final Environmental Statement prepared by FERC for the previous relicensing of the Projects (FERC 1996, as referenced in the PAD)). However, Table 5.8-3 on page 5-215 does not include Millinocket Dam boat launch, nor is it included on Figure 5.8-4 depicting FERC-approved Project recreation sites at the Penobscot Mills Project.

BPL Comments
The Bureau requests clarification as to the status of the Millinocket Dam boat launch, and that the facility be added to the FERC-approved recreation sites for the ILP if appropriate, or an explanation why this should not be done.

5.8.7.1 Ripogenus Project, Existing Shoreline Buffer Zones within the Project Boundary
On pages 5-239 and 240, the document describes "the 200-foot Shoreline Buffer Zone (within the Project boundary)" and this zone is stated to exclude "campsites that are currently managed by the PRC."

Also, on page 5-240 the document states "a renewable conservation easement with the State of Maine was also established on Licensee-owned shoreline lands within 250 feet of the normal full pond elevation of Chesuncook and Ripogenus Lakes and Brandy and Black Ponds" and that

"certain campsite areas leased by the State of Maine *excluded from the Project boundary* (italics added) are included within the easement."

BPL Comments
These statements are confusing, in that all 10 of the PRC-managed campsites on Chesuncook Lake (for the present purposes, excluding the Gero Island campsites discussed above) are listed previously in the PAD as FERC-approved Project recreation sites, and are therefore within the Project boundary. This appears to contradict the exclusion of existing leased lands, including the campsites, from the 200-foot extension of the Project boundary on then-Great Northern Paper owned lands (the Shoreline Buffer Zone) as a condition of the 1996 license. BPL requests clarification regarding the 10 Chesuncook Lake campsites and the Project boundary.

The original renewable conservation easement described (Conservation Easement for Limited Duration) was executed June 7, 2002, as recorded in the Piscataquis County Registry of Deeds in Book 1393, Page 112; as amended in Book 1401, Page 191. This easement was made permanent with a Conservation Easement executed May 8, 2009, as recorded in the Piscataquis County Registry of Deeds in Book 1990, Page 149.

**Study Request, Project #2572 – Assessment of Boat Access to Chesuncook Lake with Pool Drawdown**

This study request relates to the evaluation of the existing Chesuncook Lake boat launches at Chesuncook Dam Point and Caribou Lake. As described in the PAD, the Chesuncook Dam Point facility is a single-lane gravel boat launch and the Caribou Lake facility is a primitive gravel put in.

*Criterion (1) – Describe the goals and objectives of each study proposal and the information to be obtained.*

1. The goal of this study is to evaluate the function of the Chesuncook Dam Point and Caribou Lake boat launches, thereby determining whether adequate trailered boat access is available to Chesuncook Lake through the boating season. The objectives of this study are to (a) evaluate the existing physical characteristics of the ramps (length, slope, water depth, condition) that affect the function and usability of the ramps at various pool elevations; and (b) evaluate how those characteristics and possibly other physical and environmental factors affect the ability of the public to access the waters of the lake, particularly as the annual pool drawdown proceeds.

*Criterion (2) – If applicable, explain the relevant resource management goals of the agencies or Indian tribes with jurisdiction over the resource to be studied.*

2. The study is requested to ensure that the public has trailered boat access to Chesuncook Lake throughout the ice-free time of year (generally May – November). Ensuring public boating access to the waters of the State is an important resource management goal of the Bureau. The Bureau's Boating Facilities Program has a primary role in meeting this goal.

*Criterion (3) – if the requester is not a resource agency, explain any relevant public interest considerations in regards to the proposed study.*

3. The Bureau of Parks and Lands is a resource agency; specifically, a division of the Department of Agriculture, Conservation and Forestry, a cabinet level agency of the State of Maine.

*Criterion (4) – Describe existing information concerning the subject of the study proposal, and the need for additional information.*

4. To the best of our knowledge, there is limited information available on the current physical characteristics of the boat launches (such as slope, water depth at the bottom of the launch, condition of the launch below full pond) or on functionality at all relevant pool levels. The Bureau has received complaints from the public about the function of the Chesuncook Dam Point facility at certain times of year due to low water levels impeding access to the lake. Access to the lake by BPL Penobscot River Corridor staff for management purposes is also impeded.

*Criterion (5) - Explain any nexus between project operations and effects (direct, indirect, and/or cumulative) on the resource to be studied, and how the study results would inform the development of license requirements.*

5. The annual cycle of reservoir draw-down and refilling associated with project operations has the potential to have a direct effect on the usability of boat launch facilities. The circumstance of the reservoir elevation falling below the level at which a facility was designed to function is of particular concern. The Project Operations section of the PAD (Section 4.4) describes annual changes in Chesuncook Lake elevation; this includes a 28-foot targeted seasonal drawdown range (between el. 941.6 and el. 913.6), and a maximum drawdown of 44 feet based on operational limitations of the Project. No specific date is given for the 28-foot targeted drawdown. Notably, there is no FERC-mandated minimum pool level for the lake for any time of the year.

The Bureau does not have access to and the PAD does not provide historical elevation data for Chesuncook Lake. Therefore, we are not able to characterize the adverse effect of annual drawdown on boat access with more specificity regarding lake elevation at particular times of the year. However, field staff report that access was severely impeded by mid to late summer during both 2020 and 2021, with the shoreline some distance from the end of the launches, when drought conditions prevailed in the watershed. The photos below are offered as evidence of recent conditions.

Photo 1: Chesuncook Dam Point Boat Launch, Aug. 2021 (photo taken from just above the high water line)

Photo 2: Caribou Lake Boat Launch, Aug. 2021 (photo taken from approximate high water line)

The Bureau's consideration of this issue would be greatly facilitated by daily average surface elevation data for Chesuncook Lake for each of the past 10 years, as well as annual water surface elevation curves for the same time period. The study results, which should incorporate this lake elevation data, will help the Bureau determine whether to request that the license include a requirement to improve the boat launches to function at lower lake levels, to ensure that the public has trailered boat access at all desired pool levels. Alternatively, the Bureau may request that the license include a required minimum elevation to be maintained at Chesuncook Lake through Labor Day weekend each year to ensure public boat access is available throughout the prime summer boating season, with a lower minimum to adjust for low inflows to the impoundment due to dry hydrologic conditions in the watershed.

*Criterion (6) – Explain how any proposed study methodology (including any preferred data collection and analysis techniques, or objectively quantified information, and a schedule including appropriate field season(s) and the duration) is consistent with generally accepted practice in the scientific community or, as appropriate, considers relevant tribal values and knowledge.*

6. The Licensee has proposed a Recreation Facility Inventory and Condition Assessment Study. It is our request that the proposed study evaluate the functionality as well as the condition of the boat launch facilities. This study request proposes that standard engineering and design methodology and criteria for such facilities be applied in the evaluation, to include all relevant physical dimensions of the launches (e.g., length, slope, water depth, condition), and that the study document the range of surface elevations at which the launches are fully functional. ADA compliance should also be addressed in the assessment.

If these data are not available from existing as-built drawings, we request that measurements be obtained in the field. It may be advantageous to obtain data when the pool level is at or near the annual minimum; however, the measurements could be conducted at any pool elevation (i.e.,

when a portion of the ramps may be submerged), with the proper equipment and preparation. The evaluation should include all pool levels that are normally present throughout the period of the year when the lake is ice-free in order to fully determine the adequacy of the facilities.

*Criterion (7) – Describe considerations of level of effort and cost, as applicable, and why any proposed alternative studies would not be sufficient to meet the stated information needs.*

7. The level of effort and cost is commensurate with a project the size of the Ripogenus Project and the likely license term. On-site measurement and other evaluation of the launch ramps will likely be needed to assess the function and condition of the ramps at various surface elevations. It is not expected that this on-site work, if necessary, would require more than a single day.

**Study Request, Project #2458 – Assessment of Boat Access to North Twin Impoundment (Ambajejus and South Twin Lakes) and Millinocket Lake with Pool Drawdowns**

This study request relates to the evaluation of the existing Ambajejus Lake, South Twin Lake and Millinocket Lake boat launches at Ambajejus, South Twin and Millinocket Lakes. As described in the PAD, the listed facilities are single-lane paved and gravel boat launches.

*Criterion (1) – Describe the goals and objectives of each study proposal and the information to be obtained.*

1. The goal of this study is to evaluate the function of the three Project boat launches listed above, thereby determining whether adequate trailered boat access is available to the lakes they serve through the boating season. (Project boat launches on Dolby Pond and on the West Branch below North Twin Dam are not included because the developments of which they are a part are operated in run-of-river mode, with little fluctuation in impoundment elevation.) The objectives of this study are to (a) evaluate the existing physical characteristics of the ramps (length, slope, water depth, condition) that affect the function and usability of the ramps at various pool elevations; and (b) evaluate how those characteristics and possibly other physical and environmental factors affect the ability of the public to access the waters of the lakes, particularly as the annual pool drawdown proceeds in Ambajejus and South Twin Lakes (North Twin Development).

*Criterion (2) – If applicable, explain the relevant resource management goals of the agencies or Indian tribes with jurisdiction over the resource to be studied.*

2. The study is requested to ensure that the public has trailered boat access to the Project waters throughout the ice-free time of year (generally May – November). Ensuring public boating access to the waters of the State is an important resource management goal of the Bureau. The Bureau's Boating Facilities Program has a primary role in meeting this goal.

*Criterion (3) – if the requester is not a resource agency, explain any relevant public interest considerations in regards to the proposed study.*

3. The Bureau of Parks and Lands is a resource agency; specifically, a division of the Department of Agriculture, Conservation and Forestry, a cabinet level agency of the State of Maine.

*Criterion (4) – Describe existing information concerning the subject of the study proposal, and the need for additional information.*

4. To the best of our knowledge, there is limited information available on the current physical characteristics of the boat launches (such as slope, water depth at the bottom of the launch, condition of the launch below full pond) or on functionality at all relevant pool levels.

*Criterion (5) - Explain any nexus between project operations and effects (direct, indirect, and/or cumulative) on the resource to be studied, and how the study results would inform the development of license requirements.*

5. The annual cycle of reservoir draw-down and refilling associated with project operations has the potential to have a direct effect on the usability of boat launch facilities. The circumstance of the impoundment elevation falling below the level at which a facility was designed to function is of particular concern. The Project Operations section of the PAD (Section 4.4) describes annual changes in the North Twin impoundment and Millinocket Lake elevation. Article 408 of the existing license requires that the North Twin impoundment be maintained at a relatively stable level from May 1 - August 22 annually, with a target elevation of 490.41 feet (1.5 feet below full pond) +/- 0.5 feet. A July 26, 2012 Order Approving Amendment of Article 408 set a minimum target level of 488.42 feet (3.5-foot drawdown) for the period August 22 through October 15. Article 402 of the existing license requires that the water level of Millinocket Lake be maintained between 480 feet (full pond) and 470 feet elevation year round.

The Bureau does not have access to and the PAD does not provide historical elevation data for the North Twin impoundment or Millinocket Lake. The Bureau's consideration of this issue would be greatly facilitated by daily average surface elevation data for the North Twin impoundment and Millinocket Lake for the past 10 years, as well as annual water surface elevation curves for the same time period. The study results, which should incorporate this lake elevation data, will help the Bureau determine whether to request that the license include a requirement to improve the boat launches to function at lower lake levels to ensure that the public has trailered boat access at all desired pool levels.

*Criterion (6) – Explain how any proposed study methodology (including any preferred data collection and analysis techniques, or objectively quantified information, and a schedule including appropriate field season(s) and the duration) is consistent with generally accepted practice in the scientific community or, as appropriate, considers relevant tribal values and knowledge.*

6. The Licensee has proposed a Recreation Facility Inventory and Condition Assessment Study. It is our request that the proposed study evaluate the functionality as well as the condition of the boat launch facilities. This study request proposes that standard engineering and design methodology and criteria for such facilities be applied in the evaluation, to include all relevant

physical dimensions of the launches (e.g., length, slope, water depth, condition), and that the study document the range of surface elevations at which the launches are fully functional. ADA compliance should also be addressed in the assessment.

If these data are not available from existing as-built drawings, we request that measurements be obtained in the field. It may be advantageous to obtain data when the pool levels are at or near the annual minimum; however, the measurements could be conducted at any pool elevation (i.e., when a portion of the ramps may be submerged), with the proper equipment and preparation. The evaluation should include all pool levels that are normally present throughout the period of the year when the lake is ice-free in order to fully determine the adequacy of the facility.

*Criterion (7) – Describe considerations of level of effort and cost, as applicable, and why any proposed alternative studies would not be sufficient to meet the stated information needs.*

7. The level of effort and cost is commensurate with a project the size of the Penobscot Mills Project and the likely license term. On-site measurement and other evaluation of the launch ramps will likely be needed to assess the function and condition of the ramps at various surface elevations. It is not expected that this on-site work, if necessary, would require more than one or two days.

Thank you for the opportunity to submit these comments. Please feel free to contact me at (207) 287-2163 or via email at Jim.Vogel@maine.gov if you have any questions regarding these comments and study requests.

Sincerely,

James Vogel

RE: Comments on the Pre-Application Document and Study Requests for the Ripogenus (FERC No. 2572) and Penobscot Mills (FERC No. 2458) Hydroelectric Projects

Dear Secretary Bose:

The Maine Department of Environmental Protection (Department or DEP) received and reviewed a Pre-Application Document (PAD), submitted on June 11, 2021, by Great Lakes Hydro America, LLC (GLHA, applicant), a subsidiary of Brookfield Renewable, for the Ripogenus (FERC No. 2572) and Penobscot Mills (FERC No. 2458) Hydroelectric Projects (Projects). Department staff attended the joint agency meeting for the two Projects on September 9, 2021 and reviewed appropriate Project documents to prepare the following comments and study requests.

## Authorities

Historically a Water Quality Certification (WQC) for Ripogenus was issued on April 23, 1993 by the Land Use Planning Commission (LUPC). As of a 1996 Executive Order of the Governor of the State of Maine, MDEP is the certifying agency for projects located wholly or partially in organized towns and cities. Each Project's current FERC license was issued on October 22, 1996. The proposed relicensing of the Ripogenus and Penobscot Mills Projects are subject to water quality certification provisions of Section 401 of the Federal Water Pollution Control Act (a.k.a. Clean Water Act). By the above-mentioned executive Order, the Department is the certifying agency for projects located wholly or partially in organized towns and cities, and as such has jurisdiction over the Projects.

## Project Descriptions

The Ripogenus Project is located on the West Branch in Piscataquis County, Maine, with the approximately 30-mile-long transmission line also extending into Penobscot County, Maine. The principal features of the Ripogenus Project include: 1) a 795-foot-long concrete gravity dam; 2) a 3,850-foot-long tunnel; 3) a powerhouse,wqe known as McKay Station, containing three turbine-generator units with an authorized installed capacity of 37.5 megawatts (MW); 4) a 20.8-mile-

long impoundment having a normal full pond elevation of 941.59 feet with a surface area of 29,270 acres and Umbazooksus Lake with a surface area of 1,600 acres; 5) a 29.4-mile-long transmission line; and 6) a battery energy storage system sized at a capacity of 10 MW for up to 2 hours.

The Penobscot Mills Project is located on the West Branch and Millinocket Stream in Piscataquis and Penobscot Counties, Maine, and includes five developments, in descending order from upstream to downstream, Millinocket Lake Storage, North Twin, Millinocket, Dolby, and East Millinocket, with a total authorized installed capacity of 67.9 MW.

1. The Millinocket Lake Storage Development includes: 1) an impoundment having a normal full pond elevation of 480.0 feet with a surface area of 8,640 acres; 2) a concrete and earth-filled dam, measuring approximately 635 feet in length, located at the outlet of Millinocket Lake; and 3) a pumping station containing two pumps, located approximately 6.2 miles from the dam, two 4-foot-6-inch-diameter steel pipes measuring approximately 544 feet in length, and a concrete outlet structure discharging to Ambajejus Lake (within the North Twin impoundment). No hydroelectric generating facilities are located at this development.

2. The North Twin Development includes: 1) an impoundment having a normal full pond elevation of 491.92 feet with a surface area of 17,790 acres; 2) a concrete and earth-filled dam measuring approximately 1,051 feet in length, including an intake structure and powerhouse containing three turbine-generator units and appurtenant equipment; 3) a series of six earthen dikes having a combined length of 2,530 feet, located upstream of the dam; 4) a 60 Hertz (Hz) substation containing six transformers; and 5) a transmission line approximately 4.2 miles in length that extends to the last transmission pole structure before entering GLHA’s Millinocket Substation #4.

3. The Millinocket Development includes: 1) an impoundment having a normal full pond elevation of 458.7 feet with a surface area of 1,344 acres; 2) a concrete dam (Stone Dam) measuring approximately 1,262 feet in length; 3) a gatehouse located at the dam, containing ten gates and a sluiceway; 4) three earthen dikes in Quakish Lake with a total length of 1,854 feet; 5) five earthen dikes in Ferguson Pond with a total length of 3,195 feet, a "western" canal leading from the gatehouse to Ferguson Pond, and an "eastern" canal leading from Ferguson Pond to the intake structure, all of which are used to convey water from the gatehouse at Stone Dam to the intake structure located approximately 7,300 feet from Stone Dam; 6) an intake structure containing seven headgates, located at the entrance of the penstocks; 7) six 10-foot-diameter steel penstocks and one 11-foot-diameter steel penstock ranging in length from 1,007 feet to 1,024 feet; 8) a powerhouse containing seven operable turbine-generator units, of which five are located within the former Grinder Room and two are in the Generator Room; 9) two transformers, one having a rated capacity of 30/40/50 megavolt-amperes (MVA) and one at 24/34/40 MVA; and 10) two 60 Hz transmission lines approximately 300 feet in length (one 6.9 kilovolt [kV] and one 13.8 kV).

4. The Dolby Development includes: 1) an impoundment having a normal full pond elevation of 336.2 feet with a surface area of 2,048 acres; 2) a concrete and earth-filled dam measuring approximately 1,395 feet in length, including an intake structure and powerhouse integral with the dam containing four operable turbine-generator units and other appurtenant equipment; 3) a 60 Hz substation containing one transformer having a rated capacity of 15/20 MVA and a second transformer with a rated capacity of 5 MVA; and (4) a transmission line extending approximately 2 miles to the last transmission pole structure before entering GLHA's Powersville Substation.

5. The East Millinocket Development includes: 1) an impoundment having a normal full pond elevation of 287.2 feet with a surface area of 128 acres; 2) a concrete and earth-filled dam measuring approximately 717.5 feet long, including an intake structure and powerhouse integral with the dam containing six turbine-generator units; and 3) a tailrace measuring approximately 1,050 feet long.

The Project also contains two battery energy storage systems each sized at a capacity of 10 MW for up to 2 hours (or combined capacity of 20 MW for 2-hour duration) and are located at the Millinocket Substation #4 and Powersville Substation.

**Water Quality Classifications and Standards**

Water quality standards and the water quality classifications of all surface waters of the State have been established by Maine Legislature (Title 38 M.R.S. §§ 464-468). The following classifications apply to the waters of the West Branch of the Penobscot River and Millinocket Stream affected by the operation of the Ripogenus and Penobscot Mills Projects:

"From its confluence with Chesuncook Lake to Ripogenus Dam – GPA;

From Ripogenus Dam through Ripogenus Gorge to McKay Station – Class B;

From McKay Station to its confluence with Ambajejus Lake – Class A;

North Twin Impoundment – GPA;

Millinocket Lake Impoundment – GPA;

From the outlet of Elbow Lake to the outlet of Quakish Lake and Ferguson Pond to its confluence with Millinocket Stream (includes the Back Channel) – Class C;

From the confluence with Millinocket Stream to its confluence with the East Branch of the Penobscot River, including all impoundments – Class B;

West Branch of the Penobscot River – Tributaries (includes Millinocket Stream) – Class A;

Millinocket Stream, from the railroad bridge near the Millinocket-T3 Indian Purchase boundary to its confluence with the West Branch Canal – Class B;

Millinocket Stream from the confluence of the West Branch Canal to its confluence with the West Branch of the Penobscot River – Class B."

Class GPA waters must be of such quality that they are suitable for the designated uses of drinking water after disinfection, recreation in and on the water, fishing, agriculture, industrial process and cooling water supply, hydroelectric power generation, navigation and as habitat for fish and other aquatic life. The habitat must be characterized as natural.

Class GPA waters must be described by their trophic state based on measures of the chlorophyll "a" content, Secchi disk transparency, total phosphorus content and other appropriate criteria. Class GPA waters must have a stable or decreasing trophic state, subject only to natural fluctuations, and must be free of culturally induced algal blooms that impair their use and enjoyment.

There may be no new direct discharge of pollutants into Class GPA waters[1].

Class A waters must be of such quality that they are suitable for the designated uses of drinking water after disinfection; fishing; agriculture; recreation in and on the water; industrial process and cooling water supply; hydroelectric power generation, except as prohibited under Title 12, section 403; navigation; and as habitat for fish and other aquatic life. The habitat must be characterized as natural.

The dissolved oxygen (DO) content of Class A water shall not be less than 7 parts per million or 75% of saturation, whichever is higher. The aquatic life and bacteria content of Class A water shall be as naturally occurs.

Except as provided in statute[2], direct discharges to these waters licensed after January 1, 1986 are permitted only if, in addition to satisfying all the requirements of this article, the discharged effluent will be equal to or better than the existing water quality of the receiving waters.

Class B waters must be of such quality that they are suitable for the designated uses of drinking water after treatment; fishing; agriculture; recreation in and on the water; industrial process and cooling water supply; hydroelectric power generation; navigation; and as habitat for fish and other aquatic life. The habitat must be characterized as unimpaired.

The DO content of Class B waters may not be less than 7 parts per million or 75% of saturation, whichever is higher, except that for the period from October 1st to May 14th, in order to ensure spawning and egg incubation of indigenous fish species, the 7-day mean DO concentration may

[1] M.R.S § 465-A(1)(C)
[2] M.R.S. § 465 (2)(C)

not be less than 9.5 parts per million and the 1-day minimum DO concentration may not be less than 8.0 parts per million in identified fish spawning areas[3].

Discharges to Class B waters may not cause adverse impact to aquatic life in that the receiving waters must be of sufficient quality to support all aquatic species indigenous to the receiving water without detrimental changes in the resident biological community.
Class C waters must be of such quality that they are suitable for the designated uses of drinking water supply after treatment; fishing; agriculture; recreation in and on the water; industrial process and cooling water supply; hydroelectric power generation, navigation; and as a habitat for fish and other aquatic life.

The DO content of Class C water may not be less than 5 parts per million or 60% of saturation, whichever is higher, except that in identified salmonid spawning areas where water quality is sufficient to ensure spawning, egg incubation and survival of early life stages, that water quality sufficient for these purposes must be maintained in order to provide additional protection for the growth of indigenous fish[4].

Discharges to Class C waters may cause some changes to aquatic life, except that the receiving waters must be of sufficient quality to support all species of fish indigenous to the receiving waters and maintain the structure and function of the resident biological community.

**Antidegradation**

The State's antidegradation policy provides that water quality certification may be approved only if the applicable standards of classification of the affected water body are met and existing in-stream uses and the level of water quality necessary to protect those existing uses are maintained and protected. The policy also provides that, where the actual quality of any classified water exceeds the minimum standards of the next highest classification, that higher water quality classification shall be maintained and protected.[5]

**Comments on the Pre-Application Document (PAD)**

The Department appreciates the effort of the applicant to prepare the PAD. The PAD provides an understanding of the Project facilities, the surrounding resources, and current and proposed project operations. The PAD also provides information from which issues related to relicensing can be readily identified. After review of the available documents, the Department has the following comments on the PAD:

(1) The Department acknowledges that a UAA was issued in 1992 for the Ripogenus Project and was referenced in the PAD document. A UAA typically requires studies, reports data and discusses the impacts of impoundment drawdowns on impoundment habitat. UAA's often cover extended drawdown of impoundments. As a result of the Ripogenus

[3] M.R.S § 465 (3)(B)
[4] M.R.S.§ 465(4)(B)(1) & (2)
[5] See Title 38 M.R.S.A §464(4)(F)

Development changing jurisdiction as described above in the Authorities section of this letter, the Department does not have sufficient documentation of the UAA associated with the Ripogenus Project[6]. Though the Department understands the document likely remains in effect at the Ripogenus Project[7], the Department requires the Applicant to submit the UAA for Department review and further studies on the impoundment aquatic habitat may be required in the Ripogenus Development as described below.

(2) In the PAD, the Applicant summarizes many historical water quality studies in Section 5.3.9 and asserts that water quality standards are being met throughout several impoundment and riverine sections of the West Branch of the Penobscot River related to the Ripogenus and Penobscot Mills Projects. To date, GLHA has not provided (1) the studies referenced in the PAD; or (2) operations data for any of the projects.
In the PAD the Applicant states *"…GLHA maintains that a full suite of new studies is not needed, that the vast body of information on which today's certifications and licenses are soundly based and should be relied upon for these relicensings. In addition, consistent with the Commission's criteria for study requests, the scope and extent of any new study be focused on addressing specific data gaps necessary to inform the development of license requirements."*

While broad summaries of the studies performed during the last relicensing were provided in the PAD, a synthesis of the data was not, nor were any data gaps identified by the Applicant. The Department has determined that studies previously conducted are not sufficient to demonstrate that Water Quality standards are being met at the Projects today, and that the data presented in the PAD is only a high-level summary. Without the original studies, and without operations data for each dam, MDEP cannot identify existing data gaps to inform their respective Study Requests or their PAD comments. Therefore, the Department respectively disagrees that the data on file demonstrates that they meet Classification Standards today and requests that the Applicant provide the Department with each study referenced in the PAD.

**Water Quality Study Requests**

Proposed WQ Studies

In the PAD in Tables 6.2-1 and 6.2-2 the Applicant proposes water quality studies to be conducted for both Projects.

For the Ripogenus Project, the Applicant proposes lake trophic sampling and tailwater sampling of temperature and DO at one station between the Ripogenus dam and McKay Station. GLHA proposes macroinvertebrate sampling below McKay Station as an additional study.

[6] Caribou Lake, Ripogenus Lake, Black Pond, Brandy Pond, Umbazokus Lake, Chesuntcook Lake figure 4.2-2
[7] Section 464 9-A(A)

For the Penobscot Mills Project, the Applicant identifies Millinocket Lake (deep area upstream of dam), the North Twin impoundment (deep area of Elbow Lake), the Millinocket impoundment (deep area of Ferguson Pond), the Dolby impoundment (deep area upstream of dam), and the East Millinocket impoundment (deep area upstream of dam) as study locations to conduct lake trophic sampling. Further proposed studies include tailwater temperature and DO sampling at one location in each of the riverine/tailwater areas: Millinocket Stream downstream of the Millinocket Lake Dam and the West Branch in the North Twin tailrace, downstream of Stone Dam, the Millinocket tailrace, the Dolby tailrace, and the East Millinocket tailrace. Lastly, they identify Millinocket Stream downstream of the dam, the North Twin tailrace, the Millinocket tailrace, the Dolby tailrace, and the East Millinocket tailrace as locations to sample macroinvertebrates. All studies are proposed according to MDEP protocols.

Study Requests

The Department has determined that GLHA has not proposed sufficient studies to demonstrate that either Project meets WQ standards. Further no habitat studies are proposed in any of the Project impoundments or downstream of these Projects.

It has been the Department's practice to determine the metrics, methods, timing, and duration of water quality monitoring necessary to ensure that the water quality studies meet data quality objectives. The Department requests that the applicant conduct water quality studies that include the following parameters and adhere to the Department's established sampling protocols in support of water quality certification. Formal study requests following FERC's Integrated Licensing Process (ILP) criteria are attached to this comment letter.

**Impoundment Trophic State Study -** The purpose of trophic state study is to determine if the Project impoundment and its associated basins have a stable or improving trophic state subject only to natural fluctuations and are free of algal blooms that impair the impoundment use or enjoyment. The objective of this study is to determine if the Project impoundment and its basins meets Maine Water Quality Standards, including dissolved oxygen criteria, and the designated use of recreation in and on the water. The PAD presents summarized data collected in 1991, however, these studies are insufficient to demonstrate that the various impoundment basins exhibit a stable or improving trophic state. The applicant proposes some Trophic State Studies outlined above to demonstrate whether the Project meets water quality standards.

Ripogenus

The Department requires an Impoundment Trophic State Study be conducted in the Ripogenus impoundment, including the waters of Ripogenus Lake, Caribou Lake, Brandy Pond, Black Pond, Chesuncook Lake, Umbazokus Lake. Assessment of the above-mentioned criteria provides information to evaluate the health and impact of the dam structure and operation on the West Branch of the Penobscot River. The Department requires GLHA to conduct their sampling at the deepest part of each basin identified above according to the *DEP Sampling Protocol for Hydropower Studies* (March 2021) to determine if Maine's water quality standards are met.

Penobscot Mills

The Department requires an Impoundment Trophic State Study be conducted in the Penobscot Mills impoundment, including the waters of Millinocket Lake, North Twin Development (including Ambajejus Lake, Pemadumcook Lake, and South Twin Lake), Quakish Lake and Ferguson Pond, and Dolby Pond. Similarly, the Department requires GLHA to conduct their sampling at the deepest part of each basin identified above according to the *DEP Sampling Protocol for Hydropower Studies* (March 2021) to determine if Maine's water quality standards are met.

**Impoundment Aquatic Habitat Studies -** The purpose of this study is to determine the effect of drawdowns on the impoundment or basin's littoral zone and the ability of those water bodies to support fish and other aquatic life. Measurements of Secchi disk transparency and bathymetric data are applied to determine the extent of the littoral zone in the impoundments and an assessment of the volume and surface area dewatered under normal operating conditions, to determine if at least 75% of the littoral zone remains watered at all times. The PAD references but does not present any information regarding littoral habitats associated with the various Project impoundments and the Applicant does not propose to conduct habitat assessment studies.

Ripogenus

The Ripogenus Project is operated as a water storage facility with an impoundment and multiple basins; therefore, normal operations may impact the littoral zone of the impoundment and these basins. As described above in the PAD comments section of this letter, the 1992 UAA may established that the Ripogenus Development meets the aquatic habitat and life standards for GPA waters. However, the Department requires the Applicant submit the UAA that remains in effect at the Ripogenus Project for review. The Applicant must consult with the Department during preparation of the Proposed Study Plan to determine if the Impoundment Aquatic Habitat Studies in the Ripogenus Development must be conducted.

If required, the Applicant should conduct the Impoundment Aquatic Habitat Study following the "Habitat Study" protocol under "Lakes, Ponds, and Impoundments" in the *DEP Sampling Protocol for Hydropower Studies* (March 2021), which is attached to this comment letter. The Department requests that this study be conducted in the Ripogenus impoundment, including the waters of Ripogenus Lake, Caribou Lake, Brandy Pond, Black Pond, Chesuncook Lake, Umbazokus Lake.

Penobscot Mills

The Penobscot Mills Project is operated as a water storage facility with an impoundment and multiple basins; therefore, normal operations may impact the littoral zone of the impoundment and these basins. The Applicant does not propose to conduct habitat assessment studies. The Applicant should conduct the Impoundment Aquatic Habitat Study following the "Habitat Study" protocol under "Lakes, Ponds, and Impoundments" in the *DEP Sampling Protocol for Hydropower Studies* (March 2021), which is attached to this comment letter. The Department

requests that this study be conducted in the waters of Millinocket Lake, North Twin Development (including Ambajejus Lake, Pemadumcook Lake, and South Twin Lake), Quakish Lake and Ferguson Pond, and Dolby Pond. Information will be used to evaluate whether the project meets Maine's habitat and aquatic life criteria, and the designated use of habitat for fish and other aquatic life

**Downstream Temperature and Dissolved Oxygen -** Temperature and DO must be monitored downstream of the Project dams to ensure that discharges from the hydropower projects are sufficient to maintain the resident biological community in the downstream habitats of the Ripogenus and the Penobscot Mills Developments. Dissolved oxygen concentrations in waters downstream of each Project dam must meet Maine water quality criteria as classified in 38 M.R.S. § 467. The Project PAD indicates that water quality in the West Branch of the Penobscot River meets all applicable water quality standards, however such assertions are based on samples collected in 1991, prior to an application for a new FERC license for the Project and may not be representative of current water quality conditions. The PAD indicates that temperature and DO monitoring is planned for these Projects.

Ripogenus

The Department requires temperature and DO to be sampled downstream of the Ripogenus dam and downstream of McKay Station. Assessment of temperature and DO data in the downstream reaches will be used to determine if the hydropower project currently meets Maine Water Quality Standards including Class B and Class A DO criteria, respectively. Data must be collected in accordance with the Department's "Temperature and Dissolved Oxygen Study" protocol under "Rivers and Streams" in the *DEP Sampling Protocol for Hydropower Studies* (March 2021), which is attached to this comment letter. As noted in the protocol, the applicant will need to consult with the Department to verify representative sampling locations as the study plan is developed.

Penobscot Mills

The Department requires temperature and DO to be sampled downstream of the Millinocket Lake Storage Development dam and the North Twin Development dam, downstream of the Stone dam[8], in Millinocket Stream within the tailrace of the Millinocket Development dam, downstream of the Dolby Development dam and downstream of the East Millinocket Development dam. Assessment of temperature and DO data in the downstream reaches will be used to determine if the hydropower project currently meets Maine Water Quality Standards including Class A, Class B and Class C DO criteria, in accordance with classification standards established within 38 M.R.S. § 467. Data must be collected in accordance with the Department's "Temperature and Dissolved Oxygen Study" protocol under "Rivers and Streams" in the *DEP Sampling Protocol for Hydropower Studies* (March 2021), which is attached to this comment letter. As noted in the protocol, the applicant will need to consult with the Department to verify representative sampling locations as the study plan is developed.

[8] In the original channel of the West Branch of the Penobscot River, also referred to as the Back Channel.

**Aquatic Habitat Cross-Sectional Flow Study -** The purpose of this study is to evaluate whether current Project operations affect attainment of habitat standards for fish and other aquatic life in the river below the Ripogenus and Penobscot Mills Developments. An aquatic habitat cross-section flow study measures depth, velocity, and wetted width along established transects at various discharges to determine flows where at least 75% of the stream cross-sectional area has enough water to provide sufficient habitat for fish and other aquatic organisms. Agency file review indicates data is insufficient and the Applicant does not propose to conduct downstream habitat assessment studies.

Ripogenus

The Department requires that the Applicant assess aquatic habitat downstream of the Ripogenus dam. Data will be evaluated to determine if the downstream waters provide sufficient quantity of water to maintain riverine aquatic habitat in the bypass and tailrace reaches. The Applicant must conduct the Cross-Sectional Flow Study following the "Habitat and Aquatic Life Studies" protocol under "Rivers and Streams" in the *DEP Sampling Protocol for Hydropower Studies* (March 2021), which is attached to this comment letter.

Penobscot Mills

The Department requires that the Applicant assess aquatic habitat downstream of the Penobscot Mills dams at Millinocket Lake, North Twin Development, Quakish Lake (Stone dam) and Ferguson Pond (powerhouse tailrace in Millinocket Stream), Dolby Development dam and East Millinocket Development dam. The Applicant must conduct the Cross-Sectional Flow Study following the "Habitat and Aquatic Life Studies" protocol under "Rivers and Streams" in the *DEP Sampling Protocol for Hydropower Studies* (March 2021), which is attached to this comment letter.

**Downstream Benthic Macroinvertebrates Study-** Assessment of the benthic macroinvertebrate community is required to determine whether current in-stream flow releases are affecting attainment of habitat and aquatic life criteria in the waters downstream of these Projects. The assessment provides biological data to evaluate potential impacts caused by project operations. Replicate benthic macroinvertebrate sample collectors are deployed for a 28-day study period in the tailrace reach of the hydropower project during low flow, high temperature conditions. Agency file review indicates data is insufficient to evaluate the current aquatic community in the bypass and tailrace reaches downstream of the Project Development dams. The PAD indicates that a study of this nature is planned for the project. Sample location must be determined in coordination with the Department.

Ripogenus

The Department requires sampling of macroinvertebrates in the West Branch of the Penobscot River below the Ripogenus dam and downstream of the McKay Station powerhouse to determine whether current in-stream flow releases affect attainment of Maine habitat and aquatic life

criteria for Class B and Class A waters. The applicant must conduct this study following DEP's standard protocol *in Methods for Biological Sampling and Analysis of Maine's River and Streams* (April 2014), attached to this comment letter.

Penobscot Mills

The Department also requires sampling of macroinvertebrates in Millinocket Stream and in the West Branch of the Penobscot River downstream of the Millinocket Lake Storage Development dam, downstream of the North Twin Development dam, downstream of the Stone dam[9], in Millinocket Stream within the tailrace of the Millinocket Development dam, downstream of the Dolby Development dam and downstream of the East Millinocket Development dam. This will allow the Department to determine if current in-stream flow releases affect attainment of Maine habitat and aquatic life criteria the applicable Class A, Class B and Class C waters. The applicant must conduct this study following DEP's standard protocol in *Methods for Biological Sampling and Analysis of Maine's River and Streams* (April 2014), attached to this comment letter.

MDEP supports study requests prepared by other natural resource agencies, including but not limited to, Maine Department of Inland Fish and Wildlife (MDIFW), Maine Department of Marine Resources (MDMR), US Fish and Wildlife (USFWS), National Marine Fisheries Service (NMFS), and New Hampshire state agencies.

Thank you for the opportunity to comment on the PAD for the Ripogenus and Penobscot Mills Hydroelectric Project. If you have any questions, please contact me by phone at (207) 446-1619 or by email at Christopher.Sferra@maine.gov.

Sincerely,

Christopher O. Sferra
Hydropower Program, Project Manager
Maine Department of Environmental Protection

Maine Department of Environmental Protection
Study Request
Ripogenus Hydropower Project (FERC No. 2572)

**Impoundment Trophic State Study**

1. **Describe the goals and objectives of each study proposal and the information to the obtained.**
   Trophic state is an important indicator of water quality within the impoundment. Assessment of this criteria provides information to evaluate the health of the Ripogenus impoundment, including the waters of Ripogenus Lake, Caribou Lake, Brandy Pond, Black Pond, Chesuncook Lake, Umbazokus Lake and the impact of the dam structure and operation on the West Branch of the Penobscot River. The objective of this study proposal is to determine if the project impoundment meets Maine Water Quality Standards, including dissolved oxygen criteria, and the designated use of recreation in and on the water. This study will assess whether the trophic state of the impoundment is stable or improving.

2. **If applicable, explain the relevant resource management goals of the agencies or Indian tribes with jurisdiction over the resource to be studied.**
   The resource management goal is to ensure attainment of Maine Water Quality Standards pursuant to the provisions of the *Water Classification Program*, 38 M.R.S. Sections 464-468 and to certify attainment of such, with any necessary conditions, under Section 401 of the Federal Water Pollution Control Act (a.k.a. Clean Water Act).

3. **If the requestor is not a resource agency, explain any relevant public interest considerations in regard to the proposed study.**
   Requestor is a resource agency.

4. **Describe existing information concerning the subject of the study proposal, and the need for additional information.**
   The PAD presents summarized data collected in 1991, and the applicant proposes to conduct Trophic State Studies to demonstrate whether the Project meets water quality standards. As described in the Department's PAD comment letter, the applicant will need to demonstrate that the project operation meet dissolved oxygen and other water quality standards in the impoundment and that the trophic state is stable or declining in order to obtain water quality certification.

5. **Explain any nexus between project operations and effects (direct, indirect, and/or cumulative) on the resource to be studied, and how the study results would inform the development of license requirements.**
   Data collected will identify trophic state and may identify stratification effects on the impounded water and habitat. Information will be used to evaluate whether the project meets Maine designated uses, habitat and aquatic life criteria, and dissolved oxygen criteria, which will inform the water quality certification process.

6. **Explain how any proposed study methodology (including any preferred data collection and analysis techniques, or objectively quantified information, and a schedule including appropriate filed season(s) and duration) is consistent with generally accepted practice in the scientific community or, as appropriate, considers relevant tribal values and knowledge.**
   The DEP Sampling Protocol for Hydropower Studies (March 2021) was established by Department staff and has been used successfully throughout the State by the DEP and others. A copy of the Department protocol is attached to the PAD comment letter.

7. **Describe considerations of level of effort and cost, as applicable, and why proposed alternative studies would not be sufficient to meet the stated information needs.**
   Trophic state samples are collected twice each month for five consecutive months during open water season. An impoundment aquatic habitat study can be completed in one field season. Costs are considered reasonable given that this study is required for Maine water quality certification and is routinely completed at hydropower projects being relicensed in the State. No alternatives to this study are proposed.

Maine Department of Environmental Protection
Study Request
Penobscot Mills Hydropower Project (FERC No. 2458)

**Impoundment Trophic State Study**

1. **Describe the goals and objectives of each study proposal and the information to the obtained.**
   Trophic state is an important indicator of water quality within the impoundment. Assessment of this criteria provides information to evaluate the health of the Penobscot Mills impoundments, including Millinocket Lake, North Twin Development (including Ambajejus Lake, Pemadumcook Lake, and South Twin Lake), Quakish Lake and Ferguson Pond, and Dolby Pond, and the impact of the dam structures and operations on Millinocket Stream and on the West Branch of the Penobscot River. The objective of this study proposal is to determine if the project impoundments meet Maine Water Quality Standards, including dissolved oxygen criteria, and the designated use of recreation in and on the water. This study will assess whether the trophic state of each of the Project impoundments is stable or improving.

2. **If applicable, explain the relevant resource management goals of the agencies or Indian tribes with jurisdiction over the resource to be studied.**
   The resource management goal is to ensure attainment of Maine Water Quality Standards pursuant to the provisions of the *Water Classification Program*, 38 M.R.S. Sections 464-468 and to certify attainment of such, with any necessary conditions, under Section 401 of the Federal Water Pollution Control Act (a.k.a. Clean Water Act).

3. **If the requestor is not a resource agency, explain any relevant public interest considerations in regard to the proposed study.**
   Requestor is a resource agency.

4. **Describe existing information concerning the subject of the study proposal, and the need for additional information.**
   The PAD presents summarized data collected in 1991, and the applicant proposes to conduct Trophic State Studies to demonstrate whether the Project impoundments meet water quality standards. As described in the Department's PAD comment letter, the applicant will need to demonstrate that the project operation meet dissolved oxygen and other water quality standards in the impoundment and that the trophic state is stable or declining in order to obtain water quality certification.

5. **Explain any nexus between project operations and effects (direct, indirect, and/or cumulative) on the resource to be studied, and how the study results would inform the development of license requirements.**
   Data collected will identify trophic state and may identify stratification effects on the impounded water and habitat. Information will be used to evaluate whether the project

meets Maine designated uses, habitat and aquatic life criteria, and dissolved oxygen criteria, which will inform the water quality certification process.

6. **Explain how any proposed study methodology (including any preferred data collection and analysis techniques, or objectively quantified information, and a schedule including appropriate filed season(s) and duration) is consistent with generally accepted practice in the scientific community or, as appropriate, considers relevant tribal values and knowledge.**
   The DEP Sampling Protocol for Hydropower Studies (March 2021) was established by Department staff and has been used successfully throughout the State by the DEP and others. A copy of the Department protocol is attached to the PAD comment letter.

7. **Describe considerations of level of effort and cost, as applicable, and why proposed alternative studies would not be sufficient to meet the stated information needs.**
   Trophic state samples are collected twice each month for five consecutive months during open water season. An impoundment aquatic habitat study can be completed in one field season. Costs are considered reasonable given that this study is required for Maine water quality certification and is routinely completed at hydropower projects being relicensed in the State. No alternatives to this study are proposed.

Maine Department of Environmental Protection
Study Request
Ripogenus Hydropower Project (FERC No. 2572)

**Impoundment Aquatic Habitat Study**

1. **Describe the goals and objectives of each study proposal and the information to the obtained.**
   The objective of this study proposal is to determine if the project impoundments, including the waters of Ripogenus Lake, Caribou Lake, Brandy Pond, Black Pond, Chesuncook Lake and Umbazokus Lake meet Maine Water Quality Standards including habitat and aquatic life criteria. Measurements of Secchi disk transparency and bathymetric data are applied to determine the extent of the littoral zone in the impoundments and an assessment of the volume and surface area dewatered under normal operating conditions, to determine if at least 75% of the littoral zone remains watered at all times. Assessment of the shoreline littoral environment is necessary to evaluate the impact of Project operations on habitat there to determine if the Project attains Maine's aquatic life criteria, a narrative water quality standard.

2. **If applicable, explain the relevant resource management goals of the agencies or Indian tribes with jurisdiction over the resource to be studied.**
   The resource management goal is to ensure attainment of Maine Water Quality Standards pursuant to the provisions of the *Water Classification Program*, 38 M.R.S. Sections 464-468 and to certify attainment of such, with any necessary conditions, under Section 401 of the Federal Water Pollution Control Act (a.k.a. Clean Water Act).

3. **If the requestor is not a resource agency, explain any relevant public interest considerations in regard to the proposed study.**
   Requestor is a resource agency.

4. **Describe existing information concerning the subject of the study proposal, and the need for additional information.**
   The PAD references and existing 1992 UAA but does not present any information regarding maintenance of the littoral habitats associated with the various Ripogenus impoundments and the applicant does not propose to conduct habitat assessment studies. Through changes in jurisdiction of the Project through the LUPC and MDEP, the Department does not have adequate documentation of the UAA and the Department requests that the UAA be submitted for Department review. As described in the PAD comments, the Impoundment Habitat Studies may need to be conducted in each of the Project impoundments to demonstrate that the Project impoundments meet habitat and aquatic life criteria under the proposed operating conditions.

5. **Explain any nexus between project operations and effects (direct, indirect, and/or cumulative) on the resource to be studied, and how the study results would inform the development of license requirements.**

Data collected will identify any drawdown effects on the littoral zone habitats in each of the Project impoundments. Information will be used to evaluate whether the project meets Maine's habitat and aquatic life criteria, and the designated use of habitat for fish and other aquatic life, which will inform the water quality certification process.

6. **Explain how any proposed study methodology (including any preferred data collection and analysis techniques, or objectively quantified information, and a schedule including appropriate filed season(s) and duration) is consistent with generally accepted practice in the scientific community or, as appropriate, considers relevant tribal values and knowledge.**
   The DEP Sampling Protocol for Hydropower Studies (March 2021) was established by Department staff and has been used successfully throughout the State by the DEP and others. A copy of the Department protocol is attached to the PAD comment letter.

7. **Describe considerations of level of effort and cost, as applicable, and why proposed alternative studies would not be sufficient to meet the stated information needs.**
   The Impoundment Aquatic Habitat Study can be completed in one field season, and can be designed as a desktop study utilizing data collected in the Trophic State Study. Costs are considered reasonable given that this study is required for Maine water quality certification and is routinely completed at hydropower projects being relicensed in the State. The Applicant must submit the existing UAA and must consult with the Department concerning this study as they prepare their PSP.

Maine Department of Environmental Protection
Study Request
Penobscot Mills Hydropower Project (FERC No. 2458)

**Impoundment Aquatic Habitat Study**

8. **Describe the goals and objectives of each study proposal and the information to the obtained.**
   The objective of this study proposal is to determine if the project impoundments, including Millinocket Lake, North Twin Development (including Ambajejus Lake, Pemadumcook Lake, and South Twin Lake), Quakish Lake and Ferguson Pond, and Dolby Pond meet Maine Water Quality Standards including habitat and aquatic life criteria. Measurements of Secchi disk transparency and bathymetric data are applied to determine the extent of the littoral zone in the impoundments and an assessment of the volume and surface area dewatered under normal operating conditions, to determine if at least 75% of the littoral zone remains watered at all times. Assessment of the shoreline littoral environment is necessary to evaluate the impact of Project operations on habitat there to determine if the Project attains Maine's aquatic life criteria, a narrative water quality standard.

9. **If applicable, explain the relevant resource management goals of the agencies or Indian tribes with jurisdiction over the resource to be studied.**
   The resource management goal is to ensure attainment of Maine Water Quality Standards pursuant to the provisions of the *Water Classification Program*, 38 M.R.S. Sections 464-468 and to certify attainment of such, with any necessary conditions, under Section 401 of the Federal Water Pollution Control Act (a.k.a. Clean Water Act).

10. **If the requestor is not a resource agency, explain any relevant public interest considerations in regard to the proposed study.**
    Requestor is a resource agency.

11. **Describe existing information concerning the subject of the study proposal, and the need for additional information.**
    The PAD does not present any information regarding maintenance of the littoral habitats associated with the various Penobscot Mills impoundments and the applicant does not propose to conduct habitat assessment studies. The Department requests that Impoundment Habitat Studies be conducted in each of the Project impoundments to demonstrate that the Project impoundments meet habitat and aquatic life criteria under the proposed operating conditions.

12. **Explain any nexus between project operations and effects (direct, indirect, and/or cumulative) on the resource to be studied, and how the study results would inform the development of license requirements.**
    Data collected will identify any drawdown effects on the littoral zone habitats in each of the Project impoundments. Information will be used to evaluate whether the project

meets Maine's habitat and aquatic life criteria, and the designated use of habitat for fish and other aquatic life, which will inform the water quality certification process.

13. **Explain how any proposed study methodology (including any preferred data collection and analysis techniques, or objectively quantified information, and a schedule including appropriate filed season(s) and duration) is consistent with generally accepted practice in the scientific community or, as appropriate, considers relevant tribal values and knowledge.**
The DEP Sampling Protocol for Hydropower Studies (March 2021) was established by Department staff and has been used successfully throughout the State by the DEP and others. A copy of the Department protocol is attached to the PAD comment letter.

14. **Describe considerations of level of effort and cost, as applicable, and why proposed alternative studies would not be sufficient to meet the stated information needs.**
The Impoundment Aquatic Habitat Study can be completed in one field season, and can be designed as a desktop study utilizing data collected in the Trophic State Study. Costs are considered reasonable given that this study is required for Maine water quality certification and is routinely completed at hydropower projects being relicensed in the State. No alternatives to this study are proposed.

Maine Department of Environmental Protection
Study Request
Ripogenus Hydropower Project (FERC No. 2572)

**Downstream Temperature and Dissolved Oxygen Study**

1. **Describe the goals and objectives of each study proposal and the information to the obtained.**
   Temperature and dissolved oxygen (DO) are important indicators of water quality to ensure that discharges from the hydropower project are sufficient to maintain the resident biologic community downstream of the Ripogenus dam and downstream of McKay Station. Assessment of temperature and DO data in the downstream reaches will be used to determine if the hydropower project currently[10] meets Maine Water Quality Standards including Class B and Class A DO criteria, respectively.

2. **If applicable, explain the relevant resource management goals of the agencies or Indian tribes with jurisdiction over the resource to be studied.**
   The resource management goal is to ensure attainment of Maine Water Quality Standards pursuant to the provisions of the *Water Classification Program*, 38 M.R.S. Sections 464-468 and certify attainment of such, with any necessary conditions, under Section 401 of the Federal Water Pollution Control Act (a.k.a. Clean Water Act)

3. **If the requestor is not a resource agency, explain any relevant public interest considerations in regard to the proposed study.**
   Requestor is a resource agency.

4. **Describe existing information concerning the subject of the study proposal, and the need for additional information.**
   Dissolved oxygen concentrations downstream of the Ripogenus dam must meet Maine water quality criteria for Class B waters and must meet water quality criteria for Class A in waters downstream of the McKay Station. Agency file review indicates temperature and dissolved oxygen data are insufficient to assess current attainment of these criteria. The PAD indicates that a study of this nature is planned for the project; data collection sites must be chosen in coordination with the Department.

5. **Explain any nexus between project operations and effects (direct, indirect, and/or cumulative) on the resource to be studied, and how the study results would inform the development of license requirements.**
   Data collected will be used to evaluate project effects on water temperature and DO concentrations in the West Branch of the Penobscot River downstream of the Ripogenus

[10] The Project PAD indicates that water quality in the West Branch of the Penobscot River is good and meets all applicable water quality standards, however such assertions are based on samples collected in 1991, prior to an application for a new FERC license for the Project, and may not be representative of current water quality conditions.

dam. Information will be used to evaluate whether the project meets Maine DO criteria for Class A waters and will inform the water quality certification process.

6. **Explain how any proposed study methodology (including any preferred data collection and analysis techniques, or objectively quantified information, and a schedule including appropriate filed season(s) and duration) is consistent with generally accepted practice in the scientific community or, as appropriate, considers relevant tribal values and knowledge.**
   The DEP Sampling Protocol for Hydropower Studies (March 2021) was established by Department staff and has been used successfully throughout the State by the DEP and others. A copy of the Department protocol is attached to the PAD comment letter.

7. **Describe considerations of level of effort and cost, as applicable, and why proposed alternative studies would not be sufficient to meet the stated information needs.**
   The DEP Sampling Protocol for Hydropower Studies (March 2021) offers two options for the temperature and DO study that can be completed in one field season. Temperature and DO samples can be collected one day per week for at least 10 weeks or measured hourly using data sondes placed at designated locations during summer low flow, high water temperature conditions (e.g. July and August). The Department prefers the second method. Costs are considered reasonable given that this study is required for Maine water quality certification and is routinely completed at hydropower projects being relicensed in the State. No alternatives to this study are proposed.

Maine Department of Environmental Protection
Study Request
Penobscot Mills Hydropower Project (FERC No. 2458)

**Downstream Temperature and Dissolved Oxygen Study**

1. **Describe the goals and objectives of each study proposal and the information to the obtained.**
   Temperature and dissolved oxygen (DO) are important indicators of water quality to ensure that discharges from the hydropower project are sufficient to maintain the resident biologic community downstream of the Millinocket Lake Storage Development dam, the North Twin Development dam, downstream of the Stone dam[11], in Millinocket Stream within the tailrace of the Millinocket Development dam, downstream of the Dolby Development dam and downstream of the East Millinocket Development dam. Assessment of temperature and DO data in the downstream reaches will be used to determine if the hydropower project currently[12] meets Maine Water Quality Standards including Class A, Class B and Class C DO criteria, in accordance with classification standards[13].

2. **If applicable, explain the relevant resource management goals of the agencies or Indian tribes with jurisdiction over the resource to be studied.**
   The resource management goal is to ensure attainment of Maine Water Quality Standards pursuant to the provisions of the *Water Classification Program*, 38 M.R.S. Sections 464-468 and certify attainment of such, with any necessary conditions, under Section 401 of the Federal Water Pollution Control Act (a.k.a. Clean Water Act)

3. **If the requestor is not a resource agency, explain any relevant public interest considerations in regard to the proposed study.**
   Requestor is a resource agency.

4. **Describe existing information concerning the subject of the study proposal, and the need for additional information.**
   Dissolved oxygen concentrations in waters downstream of each Project dam must meet Maine water quality criteria as classified in 38 M.R.S. § 467. Agency file review indicates temperature and dissolved oxygen data is insufficient to assess current attainment of these criteria. The PAD indicates that a study of this nature is planned for the project; data collection sites must be chosen in coordination with the Department.

[11] In the original channel of the West Branch of the Penobscot River, also referred to as the Back Channel.
[12] The Project PAD indicates that water quality in the West Branch of the Penobscot River is good and meets all applicable water quality standards, however such assertions are based on samples collected in 1991, prior to an application for a new FERC license for the Project and may not be representative of current water quality conditions.
[13] Classification of each river reach is determined within 38 M.R.S. § 467.

5. **Explain any nexus between project operations and effects (direct, indirect, and/or cumulative) on the resource to be studied, and how the study results would inform the development of license requirements.**
   Data collected will be used to evaluate project effects on water temperature and DO concentrations in the West Branch of the Penobscot River and in Millinocket Stream downstream of each Penobscot Mills Project dam. Information will be used to evaluate whether the project meets Maine DO criteria for the appropriate classification standard and will inform the water quality certification process.

6. **Explain how any proposed study methodology (including any preferred data collection and analysis techniques, or objectively quantified information, and a schedule including appropriate filed season(s) and duration) is consistent with generally accepted practice in the scientific community or, as appropriate, considers relevant tribal values and knowledge.**
   The DEP Sampling Protocol for Hydropower Studies (March 2021) was established by Department staff and has been used successfully throughout the State by the DEP and others. A copy of the Department protocol is attached to the PAD comment letter.

7. **Describe considerations of level of effort and cost, as applicable, and why proposed alternative studies would not be sufficient to meet the stated information needs.**
   The DEP Sampling Protocol for Hydropower Studies (March 2021) offers two options for the temperature and DO study that can be completed in one field season. Temperature and DO samples can be collected one day per week for at least 10 weeks or measured hourly using data sondes placed at designated locations during summer low flow, high water temperature conditions (e.g. July and August). The Department prefers the second method. Costs are considered reasonable given that this study is required for Maine water quality certification and is routinely completed at hydropower projects being relicensed in the State. No alternatives to this study are proposed.

Maine Department of Environmental Protection
Study Request
Ripogenus Hydropower Project (FERC No. 2572)

**Aquatic Habitat Cross-Section Flow Study**

1. **Describe the goals and objectives of each study proposal and the information to the obtained.**
   Assessment of aquatic habitat downstream of the Ripogenus dam is required to determine whether current in-stream flow releases meet Maine habitat and aquatic life criteria. An aquatic habitat cross-section flow study measures depth, velocity, and wetted width along established transects at various discharges to determine flows where at least 75% of the

stream cross-sectional area has enough water to provide sufficient habitat for fish and other aquatic organisms. Data will be evaluated to determine if the downstream waters provide sufficient quantity of water to maintain riverine aquatic habitat in the bypass and tailrace reaches.

2. **If applicable, explain the relevant resource management goals of the agencies or Indian tribes with jurisdiction over the resource to be studied.**
   The resource management goal is to ensure attainment of Maine Water Quality Standards pursuant to the provisions of the *Water Classification Program*, 38 M.R.S. Sections 464-468 and to certify attainment of such, with any necessary conditions, under Section 401 of the Federal Water Pollution Control Act (a.k.a. Clean Water Act).

3. **If the requestor is not a resource agency, explain any relevant public interest considerations in regard to the proposed study.**
   Requestor is a resource agency.

4. **Describe existing information concerning the subject of the study proposal, and the need for additional information.**
   The West Branch of the Penobscot River downstream of the Ripogenus dam must meet Maine habitat and aquatic life criteria. Agency file review indicates data is insufficient in the bypass and tailrace reaches of the Ripogenus Project to assess current attainment of these criteria. The PAD indicates that no water quality studies designed to assess the extent of aquatic habitat are planned for the Project; the Department requests that water quality studies for this project include a study of this nature.

5. **Explain any nexus between project operations and effects (direct, indirect, and/or cumulative) on the resource to be studied, and how the study results would inform the development of license requirements.**
   Data collected will be used to evaluate aquatic habitat in the West Branch of the Penobscot River downstream of the Ripogenus dam, in the bypass reach and in the project tailrace. Information will be used to evaluate whether the project meets Maine habitat and aquatic life criteria and will inform the water quality certification process.

6. **Explain how any proposed study methodology (including any preferred data collection and analysis techniques, or objectively quantified information, and a schedule including appropriate filed season(s) and duration) is consistent with generally accepted practice in the scientific community or, as appropriate, considers relevant tribal values and knowledge.**
   The DEP Sampling Protocol for Hydropower Studies (March 2021) was established by Department staff and has been used successfully throughout the State by the DEP and others. A copy of the Department protocol is attached to the PAD comment letter.

7. **Describe considerations of level of effort and cost, as applicable, and why proposed alternative studies would not be sufficient to meet the stated information needs.**
A cross-section flow study measures depth, velocity, and wetted width along established transects in the bypass and tailrace reaches at various discharges to determine flows where at least 75% of the stream cross-sectional area has enough water to provide sufficient habitat for fish and other aquatic organisms. This type of study can typically be accomplished in one or two days. Costs are considered reasonable given that this study is required for Maine water quality certification and is routinely completed at hydropower projects being relicensed in the State. No alternatives to this study are proposed.

Maine Department of Environmental Protection
Study Request
Penobscot Mills Hydropower Project (FERC No. 2458)

**Aquatic Habitat Cross-Section Flow Study**

1. **Describe the goals and objectives of each study proposal and the information to the obtained.**
Assessment of aquatic habitat downstream of the Penobscot Mills dams at Millinocket Lake, North Twin Development, Quakish Lake (Stone dam) and Ferguson Pond (powerhouse tailrace in Millinocket Stream), Dolby Development dam and East Millinocket Development dam is required to determine whether current in-stream flow

releases meet Maine habitat and aquatic life criteria. An aquatic habitat cross-section flow study measures depth, velocity, and wetted width along established transects at various discharges to determine flows where at least 75% of the stream cross-sectional area, measured from bankfull width, has enough water to provide sufficient habitat for fish and other aquatic organisms. Data will be evaluated to determine if the downstream waters provide sufficient quantity of water to maintain riverine aquatic habitat in the bypass and tailrace reaches.

2. **If applicable, explain the relevant resource management goals of the agencies or Indian tribes with jurisdiction over the resource to be studied.**
   The resource management goal is to ensure attainment of Maine Water Quality Standards pursuant to the provisions of the *Water Classification Program*, 38 M.R.S. Sections 464-468 and to certify attainment of such, with any necessary conditions, under Section 401 of the Federal Water Pollution Control Act (a.k.a. Clean Water Act).

3. **If the requestor is not a resource agency, explain any relevant public interest considerations in regard to the proposed study.**
   Requestor is a resource agency.

4. **Describe existing information concerning the subject of the study proposal, and the need for additional information.**
   The West Branch of the Penobscot River and Millinocket Stream downstream of each of the Project dams must meet Maine habitat and aquatic life criteria. Agency file review indicates data is insufficient in the bypass and tailrace reaches of the Penobscot Mills Project, including the original channel of the West Branch of the Penobscot River, also referred to as the Back Channel, to assess attainment of these criteria. The PAD indicates that water quality studies are planned for the Project but does not indicate that an aquatic habitat cross-sectional flow study is planned; the Department requests that such studies include a study of this nature.

5. **Explain any nexus between project operations and effects (direct, indirect, and/or cumulative) on the resource to be studied, and how the study results would inform the development of license requirements.**
   Data collected will be used to evaluate aquatic habitat in the West Branch of the Penobscot River, including the reach of the river referred to as the Back Channel, as well as in Millinocket Stream, downstream of each of the project dams. Information will be used to evaluate whether the project meets Maine habitat and aquatic life criteria and will inform the water quality certification process.

6. **Explain how any proposed study methodology (including any preferred data collection and analysis techniques, or objectively quantified information, and a schedule including appropriate filed season(s) and duration) is consistent with generally accepted practice in the scientific community or, as appropriate, considers relevant tribal values and knowledge.**

The DEP Sampling Protocol for Hydropower Studies (March 2021) was established by Department staff and has been used successfully throughout the State by the DEP and others. A copy of the Department protocol is attached to the PAD comment letter.

7. **Describe considerations of level of effort and cost, as applicable, and why proposed alternative studies would not be sufficient to meet the stated information needs.**
A cross-section flow study measures depth, velocity, and wetted width along established transects in the bypass and tailrace reaches at various discharges to determine flows where at least 75% of the stream cross-sectional area has enough water to provide sufficient habitat for fish and other aquatic organisms. This type of study can typically be accomplished in one or two days. Costs are considered reasonable given that this study is required for Maine water quality certification and is routinely completed at hydropower projects being relicensed in the State. No alternatives to this study are proposed.

Maine Department of Environmental Protection
Study Request
Ripogenus Hydropower Project (FERC No. 2572)

**Benthic Macroinvertebrate Study**

1. **Describe the goals and objectives of each study proposal and the information to the obtained.**
Assessment of the benthic macroinvertebrate community is critical to determine whether current in-stream flow releases affect attainment of Maine habitat and aquatic life criteria for Class B and Class A waters in the West Branch of the Penobscot River below the

Ripogenus dam and downstream of the McKay Station powerhouse. The assessment provides biological data to evaluate potential impacts caused by project operations.

2. **If applicable, explain the relevant resource management goals of the agencies or Indian tribes with jurisdiction over the resource to be studied.**
   The resource management goal is to ensure attainment of Maine Water Quality Standards pursuant to the provisions of the *Water Classification Program*, 38 M.R.S. Sections 464-468 and certify attainment of such, with any necessary conditions, under Section 401 of the Federal Water Pollution Control Act (a.k.a. Clean Water Act)

3. **If the requestor is not a resource agency, explain any relevant public interest considerations in regard to the proposed study.**
   Requestor is a resource agency.

4. **Describe existing information concerning the subject of the study proposal, and the need for additional information.**
   The West Branch of the Penobscot River must meet Maine aquatic life criteria in the vicinity of the Ripogenus Project, both in the bypass reach and downstream of the Project powerhouse. Agency file review indicates data is insufficient to evaluate the current aquatic community in the bypass and tailrace reaches downstream of the Ripogenus dam. The PAD indicates that a study of this nature is planned for the project; sample locations must be determined in consultation with the Department.[14]

5. **Explain any nexus between project operations and effects (direct, indirect, and/or cumulative) on the resource to be studied, and how the study results would inform the development of license requirements.**
   Data collected will be used to evaluate the benthic macroinvertebrate community in the bypass and in the tailrace reach downstream of the Ripogenus dam. Information will be used to evaluate whether the project meets Maine aquatic life criteria and will inform the water quality certification process.

6. **Explain how any proposed study methodology (including any preferred data collection and analysis techniques, or objectively quantified information, and a schedule including appropriate filed season(s) and duration) is consistent with generally accepted practice in the scientific community or, as appropriate, considers relevant tribal values and knowledge.**
   The DEP Methods for Biological Sampling and Analysis of Maine's Rivers and Streams (April 2014) was established by Department staff and has been used successfully throughout the state by DEP and others since 1983. A copy of the Department manual is attached to the PAD comment letter.

[14] The Project PAD indicates that water quality in the West Branch of the Penobscot River is good and meets all applicable water quality standards, however such assertions are based on dated data and may not be representative of current water quality conditions.

7. **Describe considerations of level of effort and cost, as applicable, and why proposed alternative studies would not be sufficient to meet the stated information needs.**
Replicate benthic macroinvertebrate sample collectors (rock baskets or cones) are deployed for a 28-day study period in the tailrace reach of the hydropower project during low flow, high temperature conditions. Samples must be collected by a professional aquatic biologist and evaluated by a professional freshwater macroinvertebrate taxonomist. Methods are documented in the DEP manual Methods for Biological Sampling and Analysis of Maine's River and Streams (April 2014). Costs are considered reasonable given that this study is required for Maine water quality certification and is routinely completed at hydropower projects being relicensed in the State. No alternatives to this study are proposed.

Maine Department of Environmental Protection
Study Request
Penobscot Mills Hydropower Project (FERC No. 2458)

**Benthic Macroinvertebrate Study**

1. **Describe the goals and objectives of each study proposal and the information to the obtained.**
Assessment of the benthic macroinvertebrate community is critical to determine whether current in-stream flow releases affect attainment of Maine habitat and aquatic life criteria

for Class A, Class B and Class C waters, as applicable, in Millinocket Stream and in the West Branch of the Penobscot River downstream of the Millinocket Lake Storage Development dam, downstream of the North Twin Development dam, downstream of the Stone dam[15], in Millinocket Stream within the tailrace of the Millinocket Development dam, downstream of the Dolby Development dam and downstream of the East Millinocket Development dam. The assessment provides biological data to evaluate potential impacts caused by project operations.

2. **If applicable, explain the relevant resource management goals of the agencies or Indian tribes with jurisdiction over the resource to be studied.**
   The resource management goal is to ensure attainment of Maine Water Quality Standards pursuant to the provisions of the *Water Classification Program*, 38 M.R.S. Sections 464-468 and certify attainment of such, with any necessary conditions, under Section 401 of the Federal Water Pollution Control Act (a.k.a. Clean Water Act)

3. **If the requestor is not a resource agency, explain any relevant public interest considerations in regard to the proposed study.**
   Requestor is a resource agency.

4. **Describe existing information concerning the subject of the study proposal, and the need for additional information.**
   Millinocket Stream and the West Branch of the Penobscot River must meet Maine aquatic life criteria downstream of the Project dams (Millinocket Lake Storage Development dam, North Twin Development dam, Millinocket Development am, Dolby Development dam and East Millinocket Development dam, and in the bypass reach (downstream of the Stone dam, also known as the Back Channel). Agency file review indicates data is insufficient to evaluate the current aquatic community in the bypass and tailrace reaches downstream of the Project dams. The PAD indicates that a study of this nature is planned for the project; sample location must be determined in coordination with the Department.

5. **Explain any nexus between project operations and effects (direct, indirect, and/or cumulative) on the resource to be studied, and how the study results would inform the development of license requirements.**
   Data collected will be used to evaluate the benthic macroinvertebrate community in Millinocket Stream and in the West Branch of the Penobscot River downstream of each of the Project dams, including downstream of the Stone Dam in the original channel of the West Branch of the Penobscot River, also known as the Back Channel. Information will be used to evaluate whether the project meets Maine aquatic life criteria and will inform the water quality certification process.

6. **Explain how any proposed study methodology (including any preferred data collection and analysis techniques, or objectively quantified information, and a**

No alternatives to this study are proposed.

## LAKES, PONDS, AND IMPOUNDMENTS

***Applicability***
This impoundment sampling protocol shall apply to existing hydropower impoundments regardless of their waterbody classification, where existing data are insufficient (in terms of density or quality) to determine water quality.

### Trophic State Study

***Overview & Sampling Stations***
Each basin or station shall be sampled at the deepest location twice each month, at approximately 2-week intervals for at least five consecutive months during one open-water season. Sampling will consist of obtaining physical measurements as well as water samples. Water samples will be obtained using an integrated core sampler that is 10-meters long, and, when water is of adequate depth, a grab device. During August, additional water samples will be obtained. Sampling personnel must be certified for this sampling protocol annually, prior to data collection by DEP's Division of Environmental Assessment, Lake Assessment Section staff. If sampling is inadequate or certification is bypassed, a second open water season of data may be required. Additional sampling may be required due to the hydraulic or physical characteristics of a given waterbody or to the presence of significant water quality problems. Refer to Table 1 for an overview of parameters, frequency, sampling methods and detection/reporting limits.

Table 1. Summary of parameters, frequency, sampling methods and detection/reporting limits for hydropower impoundment sampling.

| Parameter | Frequency | Sampling Method | Detection/Reporting Limits |
|---|---|---|---|
| Secchi disk transparency | 2x/month | disk and water scope | 0.1 meter |
| Temperature | 2x/month | electronic meter (profile) | 0.1 ℃ |
| Dissolved oxygen | 2x/month | electronic meter (profile) | 0.2 mg/l |
| Trichromatic Chlorophyll-a (uncorrected) | 2x/month | core tube | 0.001 mg/L |
| Water Chemistry | 2x/month; additional samples in August | core tube or grab device | See Table 2 below |

***Physical measurements***

Physical measurements will include the determination of water transparency using a Secchi disk and water scope following the Maine Lake Assessment SOP for *Secchi Disk Transparency* (DEPLW0947R2). In addition, profiles for temperature and dissolved oxygen will be taken from the water surface to the bottom of the impoundment. Readings will be obtained, recorded, and submitted on DEP lake monitoring forms. Readings will be obtained in 1-meter increments from the surface to 15 meters in depth, then in 2 meter increments from 15 meters to 25 meters, and every 5 meters in water deeper than 25 meters; if between 15 and 25 meters, a rapid change in temperature or oxygen is discovered, readings will be taken at 1 meter intervals until they stabilize. Refer to the Maine Lake Assessment SOP for obtaining Dissolved Oxygen/Temperature Profiles using electronic meters for additional details (DEPLW0941R2). If a multiparameter device is used that can also measure pH and specific conductance, these data may be substituted for lab data, providing that calibration and quality control check records are maintained and submitted with the data.

***Epilimnetic core samples***

The depth to which an integrated epilimnetic sample will be obtained using a core tube will be determined according to the Maine Lake Assessment SOP for *Epilimnetic Core Sample Collection* (DEPLW0946R2). Water samples collected through the season will be analyzed for uncorrected chlorophyll-a by the trichromatic method, total phosphorus, color, pH and alkalinity. Water samples collected in August will be additionally analyzed for nitrate, TKN, DOC, iron, calcium, magnesium, total and dissolved aluminum, sodium, potassium, silica, specific conductance, chloride, and sulfate. Refer to Table 2 for specific requirements; obtain bottles and preservatives from the analytical lab. In impoundments that do not thermally stratify (no change in temperature greater than or equal to 1℃ per meter below a depth of 2 meters from the water surface), the core sample will be collected to 1 meter above the bottom, unless dissolved oxygen is less than or equal to 2 ppm, in which case the sample should be collected to the meter above that depth.

During warmer times of the year, if the lake is deep enough to stratify, examine the dissolved oxygen / temperature profile to determine the depth of the true seasonal epilimnion using the 1℃ change over 1 meter of depth rule below a depth of 2 meters. Be aware that within the true or seasonal epilimnion, a shallow, secondary ephemeral (temporary) epilimnion can form in the top few meters of water as a result of a few calm, warm days. Take the core sample to 1-meter below the bottom of the true epilimnion so as to include neutrally-buoyant algal growth at the epi/metalimnion interface. Elevated dissolved oxygen lower in the profile may indicate need to extend the core deeper to capture the algae responsible for the oxygen spike. Because Chlorophyll

samples are generally obtained from the core sample, never incorporate any water having 2 ppm of oxygen or less into the sample.

***Grab samples***

During late summer (mid to late August depending on latitude and weather conditions), in stratified lakes, grab samples will be obtained using a Kemmerer, Van Dorn or similar device, according to the Maine Lake Assessment SOP for the *Collection of Grab (discrete) Samples* (DEPLW0949R2). The grab samples will be analyzed for total phosphorus, color, pH, alkalinity, TKN, DOC, iron, calcium, magnesium, total and dissolved aluminum, sodium, potassium, silica, specific conductance, chloride, and sulfate. Refer to Table 2 for additional details.

If the lake does not stratify, no grab samples are needed. Otherwise, the number of grab samples taken is determined by the depth and thermal stratification pattern in the lake. In lakes deep enough to thermally stratify into 3 layers, grabs will be obtained from the metalimnion and hypolimnion. The metalimnetic sample will be taken 1 meter below the depth to which the integrated epilimnetic core sample was taken, and the hypolimnetic sample will be taken a meter above the bottom of the impoundment. In lakes that only stratify thermally into 2 layers, only one grab depth is necessary; in this case the grab sample will be obtained a meter above the bottom of the impoundment.

| Table 2. Summary of water sampling parameters, reporting levels, frequency, and sample types limits for hydropower impoundment sampling. | | | | |
|---|---|---|---|---|
| **Parameter** | **Reporting Level** | **2x per month** | **August** | **Sample types** |
| Trichromatic Chlorophyll a (uncorrected) | 0.001 mg/L | X | X | core |
| Total phosphorus | 0.001 mg/L | X | X | core & grab(s) |
| Nitrate | 0.01 mg/L | X | X | core & grab(s) |
| TKN | 0.01 mg/L | X | X | core & grab(s) |
| Color | 5.0 SPU | X | X | core & grab(s) |
| DOC | 1.0 mg/L | X | X | core & grab(s) |
| pH | 0.1 pH units | X | X | core & grab(s) |
| Total alkalinity | 1.0 mg/L | X | X | core & grab(s) |
| Total iron | 0.05 mg/L | | X | core & grab(s) |
| Total & dissolved aluminum | 0.002 mg/L | | X | core & grab(s) |
| Total calcium | 0.05 mg/L | | X | core & grab(s) |
| Total magnesium | 0.05 mg/L | | X | core & grab(s) |
| Total sodium | 0.05 mg/L | | X | core & grab(s) |
| Total potassium | 0.05 mg/L | | X | core & grab(s) |
| Total silica | 0.05 mg/L | | X | core & grab(s) |
| Specific conductance | 2 µS/cm | | X | core & grab(s) |
| Chloride | 0.5 mg/L | | X | core & grab(s) |
| Sulfate | 1 mg/L | | X | core & grab(s) |

## Habitat Study

For lakes, ponds, and riverine impoundments, determination of attainment of the designated use 'habitat for fish and other aquatic life' will be determined as follows. Using a depth of twice the mean summer Secchi disk transparency, determined from the Trophic State Study or historic DEP data, as the bottom of the littoral zone, the volume and surface area dewatered by the drawdown will be calculated to determine if at least 75% of the littoral zone remains watered at all times. Alternatively, studies of fish and other aquatic life communities, including freshwater mussels, may be conducted to demonstrate that the project maintains 'structure and function of the resident biological community' despite a drawdown that results in less than 75% of the littoral zone remaining watered at all times.

## Fishing (Mercury Contamination) Study

To ensure that the project does not contribute to the Statewide Fish Consumption Advisory due to mercury, projects with excessive drawdowns (generally >10 feet) may be required to analyze sport fish from the project waterbody and one or more reference waters for mercury. Contact DEP for specific requirements for each project.

## RIVERS AND STREAMS

### Temperature and Dissolved Oxygen Study

***Applicability***

This rivers and streams sampling protocol shall apply to tailwater areas that are not impoundments where existing data are insufficient to determine existing and future water quality.

***Sampling Stations***

Sampling shall occur in the tailwater downstream from the turbine/gate outlet or dam at a location representative of downstream flow as agreed by DEP on a case by case basis. Initially, measurements of temperature and dissolved oxygen should be made along a transect across the stream at the first, second and third quarter points across the width. If there is no violation of dissolved oxygen criteria and no significant (<0.4 mg/l) difference in concentrations among the quarter points, subsequent measurements may be made at the location shown to be representative of the main flow. Otherwise, measurements should be made at the location of the lowest concentration and the location of the main flow. Sampling should also occur in any bypassed segment of the river created by the project. Additional sampling stations may be required in the upstream or downstream areas where significant point or nonpoint sources exist or where slow moving or deep water occurs. The number and spacing of any additional stations will be determined by DEP on a case-by-case basis.

***Parameters***

Temperature and dissolved oxygen shall be sampled at mid-depth in rivers less than 2 m deep or in a profile of 1-meter increments of depth in rivers greater than 2 m deep. In rivers where it is already known that attainment of required statutory dissolved oxygen criteria is questionable, sampling for additional parameters (e.g. BOD, nitrogen, phosphorus) may be necessary.

***Frequency and Timing***

Sampling should be conducted during the summer low flow high temperature period, with the ideal conditions being the 7Q10 flow (the 7-day average low flow with a 10-year recurrence interval) combined with daily average water temperatures exceeding 24 $^{O}$C. Measurements of temperature and dissolved oxygen shall be made every hour with a data sonde in remote unattended mode continuously during July and August, unless high flows well above seasonal median flows occur.

Alternatively, with concurrence by DEP, sampling could be undertaken one day per week for a minimum of ten weeks throughout the summer low flow, high temperature period. Each discrete grab sampling event for temperature and dissolved oxygen would consist of a minimum of two daily runs, the first of which should occur before 7 AM and the second of which should occur after 2 PM. Sampling results will not be considered complete unless a minimum of 5 sampling days meets the following conditions: The product of the water temperature ($^{O}$C) and the flow duration (the percentage of the time a given flow is statistically exceeded) at the time of sampling exceeds 1500. For cycling hydropower projects, in addition to twice daily monitoring, continuous monitoring may be required at some locations for a duration equivalent to the period of one cycle of the storage and the release of flow.

For either method, a summer in which low flows and high temperatures are not experienced may result in additional sampling requirements for the next summer. Low flow conditions may occur naturally, as an unregulated river or may be artificially induced, as in the case of upstream flow regulation or flows downstream from a cycling or peaking power project or in the case of a bypassed segment which receives flow only by spillage, leakage or specific releases.

***Available Data***

The use of data already available is encouraged provided that adequate QA/QC procedures have been followed. Old data may not be acceptable for considerations of meeting minimum sampling requirements but could still provide useful information. Acceptance/rejection of data will be determined on a case by case basis, but generally data more than 10 years old may be rejected.

## Habitat and Aquatic Life Studies

For rivers and streams, determination of attainment of the designated use 'habitat for fish and other aquatic life' and "structure and function of the resident biological community" will be determined as follows. A Cross-Section Flow Study is required that measures width and depth at various flows to determine the flow at which at least 75% of the bank full cross-sectional area of the river or stream is continuously watered. At least three cross-sections representative of the river or stream must be measured. Alternately, a combination of ambient measurements in one cross-section, flow data from existing flow gages, and/or modelling may be approved by DEP.

In addition, to determine if the project 'attains the aquatic life criteria, i.e. 'maintains the structure and function of the resident biological community', biological monitoring of the benthic macroinvertebrate community must be conducted following DEP's standard protocol in Methods for Biological Sampling and Analysis of Maine's Rivers and Streams, DEP LW0387-B2002.

## FOREWORD

This manual describes the field, laboratory and data preparation methods required by the Maine Department of Environmental Protection to collect and analyze benthic macroinvertebrate samples for the River and Stream Biological Monitoring Program. The biological classification of Maine's inland waters was authorized by the Maine State Legislature with the passage of Public Law 1985 Chapter 698 - The Classification System for Maine Waters. This law states that it is the State's objective "to restore and maintain the chemical, physical and biological integrity" of its waters, and establishes a water quality classification system to enable the State to manage its waters so as to protect their quality. The classification system further establishes minimum standards for each class, which are based on designated uses, and related characteristics of those uses, for each class of water.

Each water quality class contains standards that, among other things, describe the minimum condition of the aquatic life necessary to attain that class. The Maine Department of Environmental Protection (the Department) has developed numeric criteria in support of the narrative aquatic life standards in the Water Quality Classification Law. The Department has collected a large, standardized database consisting of benthic macroinvertebrate samples from above and below all significant licensed discharges in the State, from areas impacted by non-point sources, as well as from relatively unperturbed areas. These sampling locations were chosen to represent the range of water quality conditions in the State. This information has been used to develop numeric criteria which are specific to the natural biotic community potential of the State of Maine (see Davies et al., 1995 and 1999 for a description of the development and application of numeric criteria) and is established in DEP regulation Chapter 579 : Classification Attainment Evaluation Using Biological Criteria for Rivers and Streams.

Standardization of data collection and analytical methods is fundamental to the consistent, unbiased and scientifically sound evaluation of aquatic life impacts. This manual sets forth the standardized practices and procedures used by the Department to acquire or accept benthic macroinvertebrate data for use in regulation, assessment or program development.

# I GENERAL METHODS FOR RIVER AND STREAM AQUATIC LIFE CLASSIFICATION ATTAINMENT EVALUATION

Each water quality class is defined by standards that describe the minimum condition of the aquatic community necessary to attain that class. The benthic macroinvertebrate community is used as an indicator community of the general state of the aquatic life in flowing waters for the purpose of assessment of classification attainment. Standardized sampling techniques and sample analysis are required for assessment of biological attainment of stream water quality classification. This manual presents the standard practices and procedures that have been adopted by the Department to acquire benthic macroinvertebrate data for purposes of aquatic life classification attainment evaluation.

Purpose:

To determine the water quality class attained by a particular river or stream reach in terms of the aquatic life standards set forth in 38 MRSA Sec. 465 (The Classification System for Maine Waters).

Requirements:

All samples of aquatic life that are collected for purposes of classification attainment evaluation, whether collected by the Department or by any party required to make collections by the Department, must be collected, processed and identified in conformance with the standardized methods outlined in this manual. Selection of appropriate sampling sites and micro-habitat to sample, as well as procedures for quantitative analysis of the sample must conform to methods set forth in this manual. Data submitted by any party required to make collections by the Department must be accompanied by a Quality Assurance Plan, approved by the Commissioner.

## 1. Qualifications of Sampling Personnel

Biological sampling must be performed by a professional aquatic biologist or by qualified personnel under the supervision of a professional aquatic biologist. The professional aquatic biologist must have, as a minimum, a Bachelor of Science degree in biological sciences with aquatic entomology, invertebrate zoology, fisheries or closely related specialization, and greater than 6 months experience working with macroinvertebrate sampling methods and taxonomy. (See also Qualifications of Laboratory Personnel, Sec. II-1.)

2. Apparatus, Equipment, Supplies, Instruments

(1) Sampling devices

a) Rock-filled wire basket introduced substrate

Use: flowing wadeable, eroded, mineral-based bottom rivers and streams.

Description: cylindrical plastic coated or chrome wire, baskets with at least 1.5 cm spaces between wires, a hinged opening, and secure closure (Klemm, D.J. et al, 1990).

Substrate material: clean, washed, bank-run cobble, graded to uniform diameter range of 3.8 to 7.6 cm (1.5 to 3 inches) in size (#2 roofing stone).

Baskets must be filled to 7.25 +/- 0.5 kg (16 lbs +/-1 lb) of substrate material.

b) Rock-filled mesh bag introduced substrate

Use: small flowing streams, too shallow for rock baskets to be fully submerged.

Description: mesh bags of sufficient size to hold 7.25 +/- 0.5 kg of cobble substrate as described above, with at least 2.54 cm aperture mesh, and secure closures.

c) Closing introduced substrate cone

Use: deep, non-wadeable rivers having sufficient flow to have an eroded, mineral based bottom.

Description: cone shaped wire, or plastic coated wire basket filled with substrate material and closed by means of an inverted, weighted funnel (Courtemanch, 1984).

Substrate material: (see above Rock-filled wire basket substrate material).

(2) Sieves, sieve buckets, nets

Samples are concentrated on sieves having a mesh size between 500 - 600 microns (USA Standard Testing Sieve ASTM-E-11 Specification size No. 30 or No. 35).

(3) Optical equipment

a) Binocular microscope: Magnification range from 10x or less to 30x or greater.

b) Compound microscope: Magnification range from 10x to at least 400x; 100x with oil immersion lens is advisable.

3. Sampling Season, Sampler Exposure Period, Placement and Retrieval

(1) Sampling season

The standard sampling season upon which all macroinvertebrate classification criteria are based is the late summer, low flow period (July 1 to September 30). All baseline data for the biological classification program has been collected during this time period. This period often presents conditions of maximal stress to the biological community due to decreased dilution of pollutional material and increased stream water temperatures. Furthermore, because the composition of the benthic macroinvertebrate community changes with season, due to natural life history features, this period defines a standardized seasonal community.

As noted, the Department's linear discriminant models define biological classification criteria derived from a macroinvertebrate community defined by the specific sampling methods and index season under which they were collected. Samples collected at other times of year may yield valuable water quality related information, however classification attainment may not be assigned solely on the basis of results of the linear discriminant models for these non-standard samples.

(2) Exposure period

Standard methods require that substrate samplers be exposed in the water body for a period of 28 days +/- four days within the above-specified sampling season. However, extended exposure periods may be necessary to allow for adequate colonization in the case of assessments of low velocity or impounded habitats. If such conditions exist a 56 days +/- four days exposure period may be used.

(3) Sampler placement

*Rock Baskets/Bags*

The actual sampler location should be approached so as to avoid any disturbance in, or upstream of, the sampled site. Position baskets in locations of similar habitat characteristics. Orient baskets with the long axis parallel to stream flow. Provide for relocation of baskets by flagging trees in the vicinity and/or by drawing a diagram with appropriate landmarks indicated.

*Cones*

Cone samplers should be marked with individual marker buoys (milk jugs or other suitable float) leaving about 5 extra feet of line to allow for water level changes and to provide for easy retrieval. They should be placed on the substrate with a minimum of disturbance, in an apex-up position, and located in the approximate middle fifty percent of the channel. (Note however, care should be taken not to create an obstruction to boat traffic.) In areas subject to vandalism, or in rivers having extensive macrophyte beds, it may be necessary to attach the sampler lines to a common anchor and thence to one unobtrusive surface float. Retrieval funnels will not properly close when lines are fouled with drifting macrophytes.

(4) Sampler retrieval

*Rock Baskets/ Bags*

Baskets are approached from downstream. Excessive accumulations of macrophytes, algae or debris clinging to the outside of the basket should be carefully removed, taking care to avoid jarring the basket itself. An aquatic net or drift net (mesh size 500 - 600 microns) is positioned against the substrate immediately downstream of the basket which is then quickly lifted into the net. The contents of the basket and all net washings are emptied into a sieve bucket (500 - 600 microns); the basket wires are carefully cleaned first, then rocks are hand washed and inspected and returned to the basket. All sieve bucket contents are placed in sample jars. A small amount of stream water and 95% ethyl alcohol is added to yield an approximately 70% solution of alcohol. Especially dense samples should be re-preserved in the laboratory, with fresh 70% ethyl alcohol. Rock baskets should be thoroughly cleaned and allowed to desiccate prior to re-use.

*Cones*

Cone samplers should be retrieved with the boat anchored directly upstream of the samplers. Once the float is retrieved and removed, the line should be held as vertically as possible while the weighted funnel is released down the line to enclose the cone. Cone and funnel should be retrieved quickly and smoothly from the bottom, and released directly into a sieve bucket or tub. Field processing should then proceed as described above for rock baskets.

4. Site Selection Criteria

Classification criteria apply to a strictly defined sample of the benthic macroinvertebrate community. Habitat type from which the community is obtained is a significant determinant of the make-up of the target community. Benthic macroinvertebrate communities of flowing streams and rivers having a hard, eroded substrate comprise the majority of samples in the baseline data set. This habitat is characteristic of the majority of the river and stream waters of the State. Exceptions to these conditions may require special consideration and the exercise of professional judgment. (Note: See Section III-2. (3) "Classification attainment evaluation of waters subjected to flow regulation" page 13, for procedures relating to the assessment of regulated flow sites.) While it is useful to obtain both an upstream and downstream sample to evaluate the effect of a pollution source, classification attainment evaluation does not require data from a matched reference site in order to arrive at a determination of aquatic life class. Analytical methods for classification attainment evaluation are described in Section III.

(1) Site attributes

a) The area selected should be generally representative of the habitat of the stream reach as a whole;
b) Where there is alternating riffle/pool habitat, the riffle/run is the habitat of choice;
c) A location should be selected where there is a high degree of certainty that the rock basket samples will remain fully submerged even if the water level drops significantly.

(2) Precautions

a) Avoid atypical influences such as bridges, entering culverts, channelized areas such as road crossings, culverts, or obstructions to flow;
b) Avoid bank effects: samplers should be located in the middle 50% of the bank to bank width, or in an area with a flow regime typical of the overall character of the stream segment;
c) Avoid slackwater areas and eddies immediately upstream or downstream of large rocks or debris.

(3) Matching reference and effluent impacted sites

If possible both stream reaches should be viewed prior to selection of sampling sites. Efforts should be made to sample habitats which are comparable in the following characteristics:

a) Water velocity;
b) Substrate composition (i.e., size ranges and proportions of particles making up the substrate);
c) Canopy coverage;
d) Depth;
e) Other upstream influences except the pollution source in question (for example, use caution when one site is just below a lake outfall and the other is not).

(4) Factors to be considered in site selection below point sources

The area of initial dilution of an effluent should be determined by visual observation of the plume pattern; by observations of biotic effects attributable to the plume, if evident (periphyton growth, die-off patterns); and by transects of specific conductance measurements from the outfall, in a downstream direction. The site selected should be in an area where reasonable opportunity for mixing of the effluent has occurred. If a mixing zone has been defined in a license, sampling should occur immediately downstream of it. In cases where the effluent plume channels down one bank for great distances (>1 km), or where localized effluent impact is expected to be severe for a distance beyond the zone of initial dilution, it is advisable to have a sampling site upstream of the source, one or more in the plume, and at least two farther downstream. One downstream site should be located at the point of presumed bank to bank mixing and subsequent sites should be located to assess the extent of impact downstream.

5. Sample Size

The biological community is evaluated on the basis of benthic macroinvertebrates obtained from at least three samplers which yield an average of at least 50 organisms per sampler. Matched upstream and downstream sites must be sampled using identical methods and level of effort, preferably by the same personnel.

Subsampling may be performed on samples if the mean number of organisms in a sampler exceeds 500 and subsampling will yield at least 100 organisms per rock/cone sampler. All samplers in a site should be treated consistently. Subsampling methods are described in Section II-5. Note: Subsampling will

reduce sample richness by an indeterminate amount. This may affect the outcome of linear discriminant analysis. See Section III-2. (2).

6. Physical Habitat Evaluation

A field data sheet (Appendix A) is to be completed at the time of sampler placement. This form records site specific information concerning natural variables that may affect community structure. Items addressed include exact site location (latitude and longitude, narrative description of the mapped location and/or a topographic map with site indicated); substrate composition; canopy coverage; land use and terrain characteristics; water velocity, temperature, dates of exposure and investigator name. The form is to be completed by observation as well as instrument measurement of water velocity, specific conductance, dissolved oxygen, global positioning device, temperature, etc.

## II LABORATORY METHODS

1. Qualifications of Laboratory Personnel

Sample processing and taxonomy in the laboratory must be performed or supervised by a professional freshwater macroinvertebrate taxonomist who is certified by the Society of Freshwater Science in the identification of eastern US taxa. Certification must include Genus level categories, such as Ephemeroptera, Plecoptera and Trichoptera (EPT), General Arthropods and Chironomidae taxa. Taxonomic data will not be accepted without verification that the supervising laboratory taxonomist has been certified in relevant categories.

2. Sample Preservation, Sorting

All sample material collected in the field, as described in Section I, is preserved in 70% ethyl alcohol. Samples are stored in airtight containers until sorted. Sorting of macroinvertebrates from detritus and debris should follow methods described in Appendix B. One out of every ten samples is evaluated by a biologist for sorting completeness.

After sorting, recommended storage for macroinvertebrates is in 70% ethyl alcohol with 5% glycerin, in vials sealed with tightly fitting rubber stoppers.

3. Sample Labeling

All samples are labeled in the field immediately upon collection. The label must include the following information:

Date of sample retrieval
Waterbody
Town or target discharge
Whether above or below the discharge (if applicable)
Replicate number

4. Sample Log Book

In the laboratory, the samples from each sampled site are to be assigned a sample log number, written on all items generated by the sample (e.g., sample vials, slides, records, count sheets, etc.). Log numbers are sequentially recorded in a master log book. The log book shall also contain site identification, date of placement and retrieval, investigator name, sampler type and any comments regarding sampler retrieval or data quality.

5. Subsampling

(1) Methods

If it is determined that a sample should be subsampled (see criteria in Section I-5 Sample Size) methods of Wrona et al, (1982) are followed. These are summarized below:

a) Fit a plastic or glass Imhoff-type settling cone with an aquarium air stone sealed in the bottom and connected to a compressed air supply.

b) Place the sorted macroinvertebrate sample in the cone and fill the apparatus with water to a total volume of one liter.

c) Agitate gently for 2 to 5 minutes with the air stone.

d) Remove 25% of the sample in 5 aliquots with a wide-mouth 50 ml dipper and combine into one sample vial. The dipper should be submerged and withdrawn over a five second interval.

e) Ascertain whether or not the required 100 organisms have been obtained in the subsample.

f) Indicate clearly on the sample label and on the data sheet the fraction of the sample that the subsample represents.

(2) Precautions

a) Especially large or dense organisms such as crayfish, molluscs or caddisflies with stone cases, which do not suspend randomly in the sample, should not be included in the subsample. They should be counted separately.

b) When removing aliquots, the subsampler should be careful to avoid biased capture of organisms in the cone. Avoid watching the cone as the dipper is withdrawn.

This method has been tested by the Department and has been found to randomly distribute the sample. The five separate counts conform to a Poisson series and thus can be combined into one sample (Elliott, 1979).

(3) Chironomidae subsampling

A subsampling plan for Chironomidae shall be approved by the Department. A Department recommended subsampling plan follows the following criteria:

a) For samples having less than 100 midges, all midges will be identified to genus/species level.

b) For samples having 100 to 199 midges, a subsample of one half (0.5) will be removed by randomly selecting the specimens to be identified and identified to genus/species level. Remaining unsampled midges will be examined for unusual or rare specimens, which will be removed and identified to genus/species level separate from the subsample of the sample.

c) For samples having 200 to 499 midges, a subsample of one quarter (0.25) will be removed by randomly selecting the specimens to be identified and identified to genus/species level. Remaining unsampled midges will be examined for unusual or rare specimens, which will be removed and identified to genus/species level separate from the subsample of the sample.

d) For samples having 500 or more midges, midges will be grouped by genus for those for which it is possible to confidently identify them to genus level without mounting. For remaining midges not grouped by genus, a subsample of 100 specimens will be randomly selected and identified to genus/species level. Remaining unsampled midges will be examined for unusual or rare specimens, which will be removed and identified to genus/species level separate from the subsample of the sample.

e) Reporting of the subsample of the sample will be as follows. Numbers reported on the Excel spreadsheet will be converted to reflect the sample total. Any round-off errors between the subsample total and the sample total will be equalized by adding or deducting the difference from the most numerous taxon. If unusual or rare specimens are removed from the sample following the subsample removal, the conversion of the subsample total to a "partial" sample total will be based on the sample total minus the number of unusual or rare specimens. Following this procedure, the number of unusual or rare specimens will be added to the "partial" sample total to bring it back to the sample total.

6. Sample Taxonomy

All taxonomic data submitted to the Department must be accompanied by the name(s) of the individual(s) actually performing the identifications. A list of taxonomic references used, and a reference collection of organisms must also be submitted (see below).

(1) Taxonomic resolution

Macroinvertebrate organisms are identified to genus in all cases where possible. If generic keys are not available or taxonomic expertise is lacking for a taxon it should be identified to the lowest level possible. Identification of organisms to species is highly recommended whenever possible. Although quantitative analysis of benthic macroinvertebrate samples by the Department is based on counts adjusted to the generic level of resolution, species designations are recorded in the Department database and can contribute to the final stage of data analysis, Professional Judgment Evaluation of the model outcome. This is especially important for Class Insecta. Taxonomists submitting data for use by the Department must use current taxonomic references.

(2) Identification of Chironomidae

Specimens of chironomid midges are identified from slide mounts of the cleared head capsule and body parts. Euparol or Berlese mounting medium is recommended for preparation of slides. CMCP-9 is recommended for the preparation of permanent slide mounts of reference material, for voucher specimens or for permanent collections. These slides should be prepared under a fume hood. Instructions for preparation and slide mounting may be found in Wiederholm, (1983). In samples in which a given taxon is represented by a large number of individuals, the identification to genus may be made from slide mounts of a sufficient proportion of the individuals to give a high degree of certainty that they are all the same (10-50% depending on

the distinctiveness of the taxon visible under binocular microscope). A subsampling plan for Chironomidae is described in Section II-5. Each permanent slide mount is to be fully labeled or coded in a manner which positively associates the slide with the sample from which it originated.

(3) Quality control

All organisms and records from any sampling event intended to serve regulatory purposes must be preserved for a period of at least ten years. In the course of identifying taxa collected as part of the Department's biological monitoring program, or in other collection activities, a special reference collection of separate taxa is established. This collection allows subsequent identifications of the same taxon to be confirmed and thus serves to standardize taxonomy for the program.

Each contracted taxonomist, working for the Department or working for anyone submitting data to the Department, will be required to submit a reference collection of taxa identified, as well as a list of the taxonomic references used in the identifications. Organism identifications will be checked against the Department's collection by a Department taxonomist.

## III ANALYTICAL METHODS

In general, it is the responsibility of the Department, or its agents, to conduct sampling for the purpose of making decisions on the attainment of water quality classification. Under certain conditions, sampling may be required of applicants for waste discharge licenses, or applicants requiring Section 401 Water Quality Certification. Sampling may be performed by corporations, businesses, organizations or individuals who can demonstrate their qualifications and ability to carry out the Department's sampling and analytical protocol, described in this manual. Such monitoring will be conducted according to a quality assurance plan provided to the Department and approved by the Commissioner.

Classification attainment evaluation is established in DEP regulation Chapter 579: Classification Attainment Evaluation Using Biological Criteria for Rivers and Streams. Davies et al, 1995 details the conceptual and technical basis for the State’s application of linear discriminant analysis to assess attainment of aquatic life standards. A synopsis of Chapter 579 follows in this section.

1. Minimum Provisions

Properly collected and analyzed samples that fail to achieve the following criteria are unsuitable for further analysis through the numeric criteria statistical models:

- Total Mean Abundance must be at least *50* individuals (average per basket/bag/cone);
- Generic Richness for three replicate basket/bag/cone samplers must be at least *15*.

Samples not attaining these criteria shall be evaluated by Professional Judgment. A determination will be made whether the affected community requires re-sampling or whether the community demonstrates non-attainment of minimum provisions of the aquatic life standards.

2. Aquatic Life Statistical Decision Models

The four statistical decision models consist of linear discriminant functions developed to use quantitative ecological attributes of the macroinvertebrate community (Appendix C-1) to determine the strength of the association of a test community to any of the water quality classes (Appendix D). The coefficients or weights are calculated using a linear optimization algorithm to minimize the distance, in multivariate space, between sites within a class, and to maximize the distance between sites between classes.

(1) Linear discriminant models

The discriminant function has the form:

$$Z = C + W_1X_1 + W_2X_2 + ...W_nX_n$$

Where: Z = discriminant score
C = constant
$W_i$ = the coefficients or weights
$X_i$ = the predictor variable values

Association values are computed, using variable values from a test sample, for each classification using one four-way model and three two-way models. The four-way model uses nine variables pertinent to the evaluation of all classes and provides four initial probabilities that a given site attains one of three classes (A, B, or C), or is in non-attainment (NA) of the minimum criteria for any class. These probabilities have a possible range from 0.0 to 1.0, and are used, after transformation, as variables in each of the three subsequent final decision models. The final decision models (the three, two-way models)

are designed to distinguish between a given class and any higher classes as one group and any lower classes as the other group (i.e., Classes A+B+C vs. NA; Classes A+B vs. Class C+NA; Class A vs. Classes B+C+NA). The equations for the final decision models use the predictor variables relevant to the class being tested (Appendix E). The process of determining attainment class using association values is outlined in Appendix F.

(2) Application of professional judgment

Where there is documented evidence of conditions which could result in uncharacteristic findings, allowances may be made to account for those situations by adjusting the classification attainment decision through use of professional judgment as provided in DEP regulation Chapter 579: Classification Attainment Evaluation Using Biological Criteria for Rivers and Streams. The Department may make adjustments to the classification attainment decision based on analytical, biological, and habitat information or may require that additional monitoring of affected waters be conducted prior to issuing a classification attainment decision.

Professional Judgment may be utilized when conditions are found that are atypical to the derivation of the linear discriminant model. Factors that may allow adjustments to the model outcome include but are not limited to:

a) Habitat factors
- Lake outlets
- Impounded waters
- Substrate characteristics
- Tidal waters

b) Sampling factors
- Disturbed samples
- Unusual taxa assemblages
- Human error in sampling

c) Analytical factors
- Subsample vs. whole sample analysis
- Human error in processing

(3) Classification attainment evaluation of waters subjected to flow regulation

The Maine State Legislature, in 38 MRSA Article 4-A Sec. 464 (9)-(10), *The Water Classification Program*, acknowledges that changes to aquatic life and habitat occur as the result of the impoundment of riverine waters and has modified the standards of waters so affected. The habitat and aquatic life criteria of riverine impounded waters of Class A, Class B or Class C are

deemed to be met if the impoundment attains the standards of Class C (e.g., maintenance of structure and function of the resident biological community). Impoundments managed as Great Ponds must also attain Class C aquatic life standards. If the actual water quality attains any more stringent characteristic or criterion than the Class C standards dictate, then the waterbody must be managed so as to protect those higher characteristics. Class C standards also apply to the *downstream* waters below certain specified riverine impoundments on the Kennebec River and the Saco River (Wyman Dam, Moosehead East Outlet Dam, West Buxton Dam and Skelton Dam) that are classified as A or B. All other waters subjected to flow regulation are managed according to standards of the water quality classification assigned by the Legislature.

(4) Adjustments of a decision

It is the responsibility of the Department to decide if adjustments of a decision should occur. The following adjustments may be made to correct for these conditions:

a) Resample
The Department may require that additional monitoring of the test community be done before a determination of class attainment can be made, based on documented evidence of specific sampling factors that may have influenced the results.

b) Raise the finding
   i. The Department may raise the classification attainment outcome predicted by the model from non-attainment of any class to indeterminate or to attainment of Class C, based on documented evidence of specific conditions, as defined above.

   ii. The Department may raise the classification attainment outcome predicted by the model from attainment in one class to attainment in the next higher class, based on documented evidence of specific conditions, as defined above.

c) Lower the finding
The Department may decide to lower the classification attainment finding, on the basis of documented, substantive evidence that the narrative aquatic life criteria for the assigned class are not met.

d) Determination of non-attainment: minimum provisions not met
Samples having any of the ecological attributes not attaining the minimum provisions, and where there is no evidence of conditions which could result in uncharacteristic findings, as defined above, must be determined to be in non-attainment of the minimum provisions of the aquatic life criteria for any class.

e) Determination of attainment: minimum provisions not met
Where there is evidence of factors that could result in minimum provisions not being met, professional judgment may be used to make a professional finding of attainment of the aquatic life criteria for any class. Such decisions will be provisional until appropriate resampling is carried out.

(5) Sampling procedures do not conform

For classification attainment evaluation of test communities that do not conform to criteria provided in Section I General Methods, or Section III-1, Minimum Provisions, of this manual, and are therefore not suitable to be run through the linear discriminant models, the Department may make an assessment of classification attainment or aquatic life impact in accordance with the following procedures:

a) Approved assessment plan
A quantitative sampling and data analysis plan must be developed in accordance with methods established in the scientific literature on water pollution biology, and shall be approved by the department.

b) Determination of sampling methods
Sampling methods are determined on a site-specific basis, based on habitat conditions of the sampling site, and the season sampled:

i. Soft-bottomed substrates shall, whenever ecologically appropriate and practical, be sampled by core or dredge of known dimension or volume.

ii. The preferred method for sampling hard-bottomed substrates shall be the rock basket/cone/bag as described in Section I-2.

iii. Other methods may be used where ecologically appropriate and practical.

c) Classification attainment decisions
Classification attainment decisions may be based on a determination of the degree to which the sampled site conforms to the narrative aquatic life classification criteria provided in 38 MRSA Section 465 and found in Appendix D. The decision is based on established principles of water pollution biology and must be fully documented.

d) Site-specific impact decisions
Site-specific impact decisions may rely on established methods of analysis of comparative data between a test community and an approved reference community.

e) Determination of detrimental impact
A determination of detrimental impact to aquatic life of a test community without an approved reference community may be made if it can be documented, based on established methods of the interpretation of macroinvertebrate data, and based on established principles of water pollution biology, that the community fails to demonstrate the ecological attributes of its designated class as defined by the narrative aquatic life standards in the water quality classification law.

## Appendix B

### Instructions for Macroinvertebrate Sorters

1. Pick the sample **in small portions** (1-2 TBS of material) at a time.

2. Pick all organisms you can see. If in doubt it's usually best to include it.

3. Some types of samples can be easily floated by adding a saturated solution of Epsom salt or sugar to the water. Maintain the saturated solution for the lab by adding enough salt or sugar to water to maintain a thick layer of crystals on the bottom of the storage jar. Use the supernatant solution for picking. Large numbers of organisms can be removed with a sieve spoon from the water surface. After the floaters have been removed, proceed to pick the rest of the sample as usual. A significant portion of the sample will not float and must be picked out with forceps.

4. The sample can be considered done when a careful 45 second search, after swirling the sample, yields no further organisms.

5. The samples are picked in water but should not remain unpreserved for more than 8 hours. Be certain that the final sample vial is preserved with 70% alcohol and 5% glycerin solution when done.

6. Return the detrital material to the original sample jar and preserve with 70% alcohol.

7. Write on the sample jar label "Picked X1 (your initials)".

8. Include in the vial of organisms a slip of index card label in hard pencil (No. 2) including **all information appearing on the original jar label**:

   Log Number — River
   Date - month/day/year — Location (Town or industry name)
   whether above or below
   Basket or Cone number
   Vial number if more than 1 vial is needed per basket

   ex. Log 621 Sandy R. 9/5/97
   Below Farmington (disturbed)
   Basket 2 vial #1 of 2

9. Complete all samples from one log number before beginning a new log number.

10. Keep a record of samples picked including log number

    Basket number — Time spent per basket
    Your name — Date

## Appendix C-1

### Methods for the Calculation of Indices and Measures of Community Structure Used in the Linear Discriminant Models

Variable Number

1 **Total Mean Abundance**

Count all individuals in all replicate samples from one site and divide by the number of replicates to yield mean number of individuals per sample.

2 **Generic Richness**

Count the number of different genera found in all replicates from one site.

Counting rules for Generic Richness:

a) All population counts at the species level will be aggregated to the generic level.

b) A family level identification which includes no more than one taxon identified to the generic level is counted as a separate taxon in generic richness counts.

c) A family level identification with more than one taxon identified to generic level is not counted towards generic richness. Counts are to be divided proportionately among the genera that are present.

d) Higher level taxonomic identifications (Phylum, Class, Order) are not counted toward generic richness unless they are the only representative.

e) Pupae are ignored in all calculations.

3 **Plecoptera Mean Abundance**

Count all individuals from the order Plecoptera in all replicate samplers from one site and divide by the number of replicates to yield mean number of Plecopteran individuals per sampler.

4 **Ephemeroptera Mean Abundance**

Count all individuals from the order Ephemeroptera in all replicate samplers from one site and divide by the number of replicates to yield mean number of Ephemeropteran individuals per sampler.

5 **Shannon-Wiener Generic Diversity (Shannon and Weaver, 1963)**

After adjusting all counts to genus following counting rules in Variable 2:

$$\bar{d} = \frac{c}{N}\left(N \log_{10} N - \sum n_i \log_{10} n_i\right)$$

where: $\bar{d}$ = Shannon-Wiener Diversity
c = 3.321928 (converts base 10 log to base 2)
N = Total abundance of individuals
$n_i$ = Total abundance of individuals in the $i^{th}$ taxon

6 **Hilsenhoff Biotic Index (Hilsenhoff, 1987)**

$$HBI = \sum \frac{n_i a_i}{N}$$

where: HBI = Hilsenhoff Biotic Index
$n_i$ = number of individuals in the $i^{th}$ taxon
$a_i$ = tolerance value assigned to that taxon
N = total number of individuals in sample with tolerance values.

7 **Relative Chironomidae Abundance**

Calculate the mean number of individuals of the family Chironomidae, following counting rules in Variable 4, and divide by total mean abundance (Variable 1).

8 **Relative Diptera Richness**

Count the number of different genera from the Order Diptera, following counting rules in Variable 2, and divide by generic richness (Variable 2).

9 ***Hydropsyche* Mean Abundance**

Count all individuals from the genus *Hydropsyche* in all replicate samplers from one site, and divide by the number of replicates to yield mean number of *Hydropsyche* individuals per sampler.

10 **Probability (A + B + C) from First Stage Model**

Sum of probabilities for Classes A, B, and C from First Stage Model.

11 ***Cheumatopsyche* Mean Abundance**

Count all individuals from the genus *Cheumatopsyche* in all replicate samplers from one site and divide by the number of replicates to yield mean number of *Cheumatopsyche* individuals per sampler.

12 **EPT - Diptera Richness Ratio**

EPT Generic Richness (Variable 19) divided by the number of genera from the order Diptera, following counting rules in Variable 2. If the number of genera of Diptera in the sample is 0, a value of 1 is assigned to the denominator.

13 **Relative Oligochaeta Abundance**

Calculate the mean number of individuals from the Order Oligochaeta, following counting rules in Variable 4, and divide by total mean abundance (Variable 1).

14 **Probability (A + B) from First Stage Model**

Sum of probabilities for Classes A and B from First Stage Model.

15 **Perlidae Mean Abundance (Family Functional Group)**

Count all individuals from the family Perlidae (Appendix C-3) in all replicate samplers from one site and divide by the number of replicates to yield mean number of Perlidae per sampler.

16 **Tanypodinae Mean Abundance (Family Functional Group)**

Count all individuals from the subfamily Tanypodinae (Appendix C-3) in all replicate samplers from one site and divide by the number of replicates to yield mean number of Tanypodinae per sampler.

17 **Chironomini Mean Abundance (Family Functional Group)**

Count all individuals from the tribe Chironomini (Appendix C-3) in all replicate samplers from one site and divide by the number of replicates to yield mean number of Chironomini per sampler.

18 **Relative Ephemeroptera Abundance**

Variable 4 divided by Variable 1.

19 **EPT Generic Richness**

Count the number of different genera from the Order Ephemeroptera (E), Plecoptera (P), and Trichoptera (T) in all replicate samplers, according to counting rules in Variable 2, generic richness.

20 **Variable Reserved**

21 **Sum of Mean Abundances of**: ***Dicrotendipes, Micropsectra, Parachironomus* and *Helobdella***

Sum the abundance of the 4 genera and divide by the number of replicates (as performed in Variable 4).

22 **Probability of Class A from First Stage Model**

Probability of Class A from First Stage Model.

23 **Relative Plecoptera Richness**

Count number of genera of Order Plecoptera, following counting rules in Variable 2, and divide by generic richness (Variable 2).

24 **Variable Reserved**

25 **Sum of Mean Abundances of *Cheumatopsyche, Cricotopus, Tanytarsus* and *Ablabesmyia***

Sum the number of individuals in each genus in all replicate samplers and divide by the number of replicates (as performed in Variable 4).

26 **Sum of Mean Abundances of *Acroneuria* and *Stenonema***

Sum the number of individuals in each genus in all replicate samplers and divide by the number of replicates (as performed in Variable 4).

27 **Variable Reserved**

28 **Ratio of EP Generic Richness**

Count the number of different genera from the order Ephemeroptera (E), and Plecoptera (P) in all replicate samplers, following counting rules in Variable 2, and divide by 14 (maximum expected for Class A).

29 **Variable Reserved**

30 **Ratio of Class A Indicator Taxa**

Count the number of Class A indicator taxa as listed in Appendix C-2 that are present in the community and divide by 7 (total possible number).

## Appendix C-2

### Indicator Taxa: Class A

*Brachycentrus* (Trichoptera: Brachycentridae)
*Serratella* (Ephemeroptera: Ephemerellidae)
*Leucrocuta* (Ephemeroptera: Heptageniidae)
*Glossosoma* (Trichoptera: Glossosomatidae)
*Paragnetina* (Plecoptera: Perlidae)
*Eurylophella* (Ephemeroptera: Ephemerellidae)
*Psilotreta* (Trichoptera: Odontoceridae)

## Appendix C-3

### Family Functional Groups

PLECOPTERA

Perlidae
*Acroneuria*
*Attaneuria*
*Beloneuria*
*Eccoptura*
*Perlesta*
*Perlinella*
*Neoperla*
*Paragnetina*
*Agnetina*

### Aquatic Life Standards for the State of Maine

| Classification | Biological Standards |
|---|---|
| AA | No direct discharge of pollutants; aquatic life shall be as naturally occurs. |
| A | Natural habitat for aquatic life; aquatic life shall be as naturally occurs. |
| B | Unimpaired habitat for aquatic life; discharges shall not cause adverse impact to aquatic life in that the receiving waters shall be of sufficient quality to support all aquatic species indigenous to the receiving water without detrimental changes in the resident biological community. |
| C | Habitat for aquatic life; discharges may cause some changes to aquatic life, provided that the receiving waters shall be of sufficient quality to support all species of fish indigenous to the receiving waters and maintain the structure and function of the resident biological community. |

**Re: MDIFW Comments and Study Requests for the Ripogenus Hydroelectric Project (FERC No. 2572) and Penobscot Mills Hydroelectric Project (FERC No. 2458)**

Dear Secretary Bose:

On June 11, 2021, Great Lakes Hydro America, LLC (GLHA), a subsidiary of Brookfield Renewable (Brookfield, Licensee), submitted Notices of Intent (NOI) to file an application for new licenses and a Pre-Application Document (PAD) for both the Ripogenus Hydroelectric Project (FERC No. 2572) and Penobscot Mills Hydroelectric Project (FERC No. 2458). Subsequently, FERC issued its Notice of Intend to File License Applications, Filing of Pre-Application Document, Commencement of Pre-Filing Process, and Scoping; Request for Comments on the PAD and Scoping Document, Identification of Issues and Associated Study Requests, and Virtual Public Scoping Meeting and Virtual Environmental Site Review for the Projects on August 10, 2021. Both Projects are located on the West Branch of the Penobscot River and span both Piscataquis and Penobscot Counties, Maine. The Maine Department of Inland Fisheries and Wildlife (MDIFW) is a cabinet-level agency of the State of Maine, and under Maine State Law (12 MRSA, §10051) MDIFW's mandate is "*…to preserve, protect, and enhance the inland fisheries and wildlife resources of the State; to encourage the wise use of these resources; to ensure coordinated planning for the future use and preservation of these resources; and to provide for effective management of these resources.*" Based on our statutory responsibility we have prepared the following comments on the PAD and SD1, and are submitting appropriate Study Requests:

## General Wildlife Comments

### *Endangered, Threatened, and Special Concern Species*

Bats

Of the eight species of bats that occur in Maine, the three Myotis species are afforded special protection under Maine's Endangered Species Act (MESA, 12 M.R.S §12801 et. seq.): little brown bat (State Endangered), northern long-eared bat (State Endangered), and eastern small-footed bat (State Threatened). The five remaining bat species are designated as Species of Special Concern: big brown bat, red bat, hoary bat, silver-haired bat, and tri-colored bat. While a

comprehensive statewide inventory for bats has not been completed, based on historical evidence it is likely that several of these species occur within the Project areas during migration and/or the breeding season, as indicated in the PAD. We defer to any comments of the US Fish and Wildlife Service.

Wood Turtle

Wood turtles, a State Species of Special Concern, have been documented in the vicinity of each Project, including in the West Branch of the Penobscot near River Pond and in Sandy Stream, immediately upstream of Millinocket Lake. One roadkill individual was discovered along Route 11 between Elbow and Quakish Lakes. Several verified reports of wood turtles exist from Russell Stream and the West Branch upstream of the Ripogenus impoundment; cursory desktop analyses of aerial imagery indicate that suitable wood turtle habitat is present elsewhere in the Project area. Other than an MDIFW established study site in Sandy Stream, to our Agency's knowledge no formal surveys have been conducted at either Project.

Bigmouth Pondsnail

The bigmouth pondsnail (***Stagnicola mighelsi***), a State Species of Special Concern, is known from Millinocket Lake, as well as a handful of other lakes in Maine. Little is known of this rare species in Maine except that almost all of the lakes where this rare species occurs are large, oligotrophic, and unimpounded.

Golden Eagle

Pursuant to MESA, Golden eagles (both residents and visitors) have been designated as an Endangered Species in Maine since 1986. While our Agency does not anticipate impacts to this species from Project operations, we also do not encourage winter feeding (placement of carcasses on the ice) anymore given the prevalence of lead exposure to scavenging eagles in the winter.

Rare Freshwater Mussels

As stated in the PAD, rare freshwater mussels that have been documented in the Project areas include the yellow lampmussel (State Threatened) and tidewater mucket (State Threatened). In addition, the brook floater (***Alasmidonta varicosa***), a State Threatened species, is likely in the Project area. All three species have experienced declines and extirpations throughout their ranges, and are listed as endangered, threatened, or special concern in most states where they still occur. Freshwater mussels are especially vulnerable to impacts from pollution, sedimentation, dams, and surrounding land use practices that degrade or alter aquatic habitat. It should be noted that the creeper (***Strophitus undulatus***) is no longer listed as Special Concern in Maine but remains a Species of Greatest Conservation Need.

Pygmy Snaketail

The pygmy snaketail (***Ophiogomphus howei***), a Special Concern species of dragonfly, has been documented in the West Branch downstream of the Ripogenus Project. This is one of the State's

rarest dragonflies, listed as Special Concern due to low population numbers and sensitivity to aquatic and riparian habitat degradation.

MDIFW databases do not indicate the presence of other State-listed Endangered, Threatened, or Special Concern Species in Project area; however, to our knowledge no formal surveys have been conducted. It is possible that other rare species may be resident or transient in the Project areas based on location, habitats present, and life history requirements, including one or more rare species of migratory birds during spring and fall migrations. Therefore, the list above should not be considered all-inclusive.

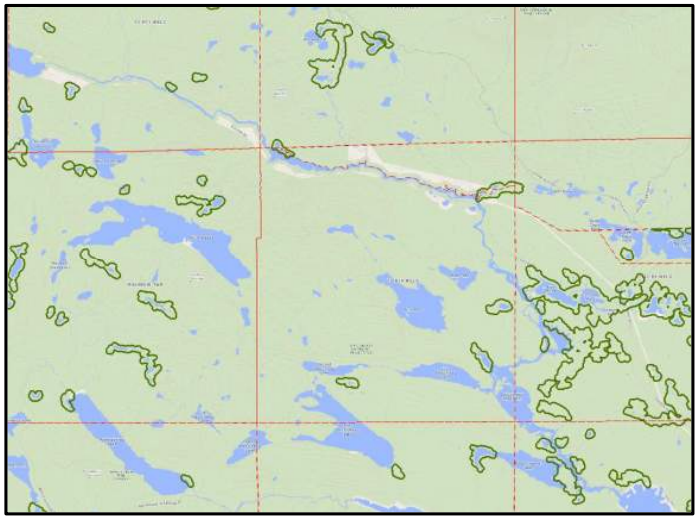
***Other Wildlife Resources of Concern***

Bald Eagle

Bald Eagles are no longer considered a State Special Concern species, although they continue to be protected under the federal Bald Eagle and Golden Eagle Protection Act as well as other federal laws. Similar to golden eagles, while our Agency does not anticipate impacts to this species from Project operations, we also do not encourage winter feeding (placement of carcasses on the ice) anymore given the prevalence of lead exposure to scavenging eagles in the winter. MDIFW defers to any comments of the US Fish and Wildlife Service.

Inland Waterfowl and Wading Bird Habitats

Both Project impoundments contain multiple Inland Waterfowl and Wading Bird Habitats (IWWH), which are considered Significant Wildlife Habitat under Maine's Natural Resources Protection Act. These habitats provide important breeding, feeding, migration, staging, and wintering habitat for waterfowl and wading bird species. Both high and moderate value IWWHs include the wetland complex and a 250-foot upland zone.



To enhance wetlands at Umbazooksus Lake, the Licensee discontinued storage and release operations in the Spring of 1998 by maintaining the outlet gate in a permanently opened position, resulting in a run-of-river regime, which has resulted in an increase of vegetation density increased over 350%, and that the total extent of vegetated wetlands has increased by ~117 acres since 1998.

It is unknown what impacts, if any, Project operations have on any of the remaining IWWHs at the Ripogenus and Penobscot Mills impoundments, as well as the productivity of breeding waterbirds utilizing these habitats, especially during the low water years, most recently 2020 and 2021. It is also unknown what impacts, if any, are occurring at IWWHs associated with the West Branch of the Penobscot River downstream of McKay Station resulting from Project operations.

**IWWHs (green polygons) associated with the Ripogenus Project**

**IWWHs (green polygons) associated with the West Branch between the Ripogenus and Penobscot Mills Projects**

**IWWHs (green polygons) associated with the Penobscot Mills Project**

**Specific PAD Comments (Wildlife)**

**Page 5-134**: *"Of the seven species found in the Project areas, the creeper, tidewater mucket and the yellow lampmussel are the rarest, with the tidewater mucket and yellow lampmussel state - listed as threatened. The creeper is a state species of special concern."*

MDIFW comments: The creeper is no longer listed as Special Concern in Maine. However, this list should include the State Threatened brook floater which is also likely to be present in the Project area. The brook floater, which is found only in streams and rivers, has not yet been documented within the Project areas but occurs throughout the Penobscot River mainstem and some of its tributaries. The closest documented occurrence for this species is at the confluence of the East and West Branch of the Penobscot River in Medway. Its host fishes (and suspected host fishes) include longnose dace, blacknose dace, golden shiner, pumpkinseed sunfish, slimy sculpin, yellow perch, brook trout, and margined madtom.

*"The yellow lampmussel has been found in the West Branch, Dolby Pond, Millinocket Stream, Pemadumcook Chain Lakes, Millinocket Lake, Passamagamet Lake, Upper, Middle and Lower Jo-Mary Lake, First and Third Debsconeag Lake, and Debsconeag Deadwater (Swartz 2007). Its host fishes (and suspected host fishes*) include white perch, yellow perch, largemouth bass, banded killifish*, chain pickerel*, white sucker*, and smallmouth bass*. The tidewater mucket has been found in Dolby Pond, Millinocket Lake, Passamagamet Lake, and Lower Jo-Mary Lake. Its host fishes (and suspected host fishes*) include the white perch, banded killifish* and alewife*(Swartz and Nedeau 2007)."*

MDIFW comments: The tidewater mucket has also been documented in the West Branch of the Penobscot River. It should also be noted that this species likely occurs throughout all the same waterbodies listed for yellow lampmussel as the two species prefer similar habitat and are often found together.

*"Both the yellow lampmussel and tidewater mucket have been declining throughout their range, prompting many states to list them as endangered or threatened species. In Maine, occurrences of these species are often limited and fragmented in distribution (Swartz and Nedeau 2007)."*

MDIFW comments: This should be changed to "*All three species have been declining…*"

**Page 5-137, Table 5.4-13:** Column heading Status, "Common" should be changed to "Not Listed". The status for creeper should be changed to "Not Listed" (see above); change "No" to "Yes" for Eastern Pearlshell.

**Page 5-157:** The first sentence, "*There are no MDIFW vernal pools or Significant Vernal Pools (SVP) mapped within the approximate boundaries of the Projects according to the MDIFW's Wildlife Habitat Data Web Mapping* Application (MDIFW 2021d)." This should be clarified to state that a comprehensive statewide inventory for Significant Vernal Pools has not been completed, and that none have been conducted in the Project area (to our knowledge).

**Page 5-192:** In the first paragraph, "*Additionally, three state-threatened aquatic species (brook floater, yellow lampmussel, and tidewater mucket) and one aquatic species of special concern (wood turtle) may occur in the vicinity of the Penobscot Mills Project as their known distribution overlaps with the Project area (Table 5.7-1).*" The wording should be corrected as each of these species, as well as the bigmouth pondsnail (Special Concern) do occur in the Project area.

**General Fisheries Comments**

***Ripogenus Project***

Regarding the Ripogenus Project, MDIFW concurs with the Licensee that there is an extensive history of inland fisheries studies associated with the Ripogenus Project completed in preparation for the 1996 license, and these studies need not be duplicated unless there are identified data gaps, or changes in operation that may impact the fisheries resources. We view this upcoming relicensing process as an opportunity to review and fine tune the water management for the Ripogenus Project.

The inland fisheries management goals for the Ripogenus impoundment and river have not changed since the last license was approved; however, there has been a significant change in the quality of the landlocked salmon fishery in both locations. The decline in salmon growth is related primarily to a surplus of salmon in the impoundment and resulting lack of smelt, the primary forage fish. MDIFW has made several changes in fishing regulations to rectify the situation, including new regulations that liberalize length and bag limits to increase harvest. The success of these management strategies is reliant on angler participation. To enhance harvest, we must increase angler use on the lake in the summer and winter. The lack of smelt in the lake has also caused a decline in smelt drift (entrainment) into the river below Ripogenus Dam. It has been well-documented that the smelt drift in the river is important to salmon growth for the riverine population. It should also be noted that the MDIFW no longer manages the lake for lake trout.

In Section 3.1.3 (pg. 20) of the Scoping Document for the Ripogenus Project, it states that "*During normal operation and normal inflow years, the Ripogenus impoundment elevation is held relatively stable at 941.6 feet during the summer months and is gradually drawn down starting in the fall, with a target low elevation of 913.6 feet by late winter, in anticipation of spring thaw and high flows.*"

MDIFW would like to have a more complete understanding of the term "relatively stable". There has been increasing concern that low impoundment elevations are occurring on a more frequent basis. MDIFW understands that 2020 and 2021 were drought years in the Penobscot drainage and these were not "normal inflow years"; however, the resulting low impoundment elevations were ***severe*** compared to other waters in the drainage and in other nearby drainages. The low water made angler access difficult, if not impossible, at several Brookfield water access sites. The lack of angler use hinders our management of the salmon fishery.

In the development of the Water Use Plan (WUP) for the current license, there was discussion of a new rule curve. This rule curve was developed using the total available storage above Ripogenus Dam and was presented in Volume VII of the relicensing documents and is attached below as the "revised elevation". MDIFW requests Brookfield provide the lake elevations individually, by year, superimposed on their rule curve developed for the current WUP for the years 1996 to present so we can determine the extent and frequency of low water conditions in the impoundment.

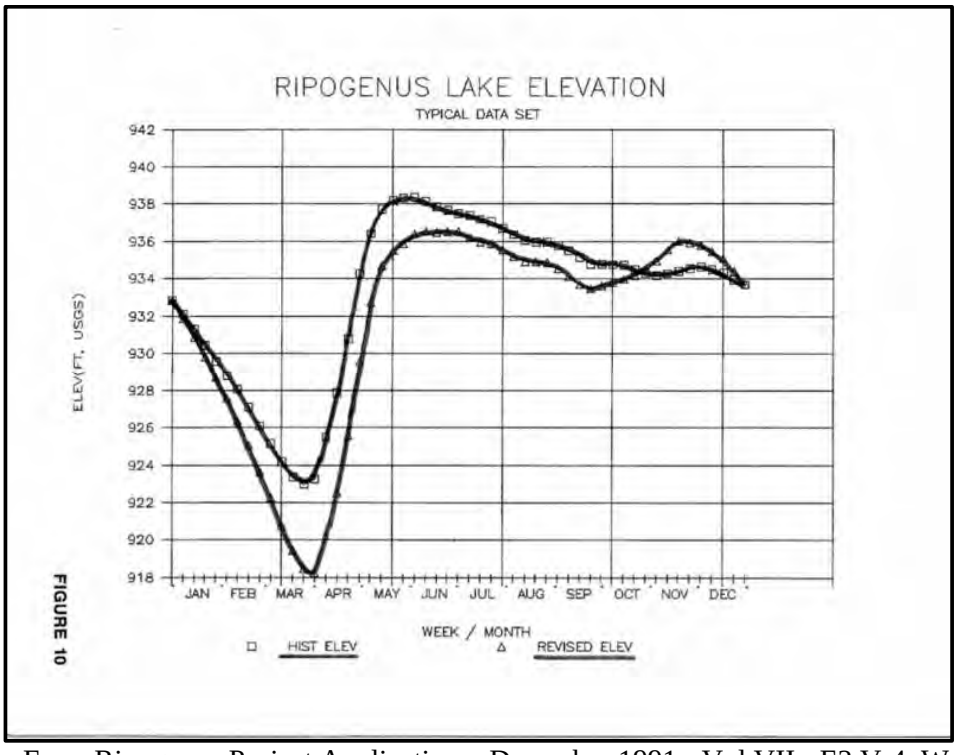


Figure 1: From Ripogenus Project Application – December 1991 - Vol VII - E2 V-4. Water Use Plan

MDIFW is concerned with the low water conditions that persisted in 2020 and 2021, and possibly other years. It has made boating access difficult for the anglers, camp owners, and the general public. It has dewatered large areas of the lake, perhaps the entire littoral zone in both 2020 and 2021, as the lake was down nearly 20 feet during the growing season. We recognize the current license has no restrictions on lake elevations and we are not implying any wrongdoing on the part of the Licensee. We view this as an opportunity to refine the current operation and perhaps minimize the unintended impacts during drought conditions.

Figure 2: Boat launch at Allagash Gateway Campground - August 2021. Note the grass growing at the end of the concrete ramp after successive years of low water. This is supposed to be the "deep water" access to the impoundment. This ramp is inoperable at lake elevations exceeding ~7 ft below full pond.

Figure 3: Parking area with sign at Caribou launch - August 2021.

Figure 4: Launch area at Caribou Lake – August 2021. For perspective, the photographer was standing at what would be the edge of the full pond water level.

Summer drawdowns greater than 10 feet expose large areas of littoral zone around the Ripogenus impoundment and could reduce the abundance and diversity of macroinvertebrates available as forage for the fish populations. Therefore, we are requesting the Licensee repeat the previous studies on macroinvertebrates in the littoral zone of the impoundment to determine if any changes have occurred.

Extreme drought conditions persisted in the summer and fall of 2020. There was a large rain event in late December of 2020 which removed the early snowpack and provided significant inflow. The remainder of the winter was dry with little snow accumulation, and it was apparent by mid-February that the drought would continue and impact the water levels in the spring of 2021. There were concerns even in these driest of years that the Licensee ran flows in excess of the required minimum flows. MDIFW observed on several occasions in the winter and summer of 2021 that the Licensee was indeed running in excess of 3,000 cfs when lower flows were required by the license; however, we do not know the frequency of these occurrences and whether they were necessary for downstream needs, and/or whether they significantly impacted lake elevations in the Ripogenus impoundment.

Peaking power operations were not discussed in the WUP for the current license and were not anticipated. The literature is replete with examples of the detrimental impacts on the riverine fisheries and aquatic communities from rapid changes in flow. Flow changes of less than 25% per hour (ramping rate) can mitigate impacts from peaking power. As noted, we are requesting flow records to evaluate the frequency of flow changes that exceed 25% (see below). We have received anecdotal reports from anglers on the West Branch that insect hatches are less frequent and less intense than in the past. We think it would be prudent if the Licensee repeated the macroinvertebrate studies completed in the river for the current license to determine if any changes have occurred.

MDIFW recognizes that entrainment occurs at Ripogenus Dam/McKay Station. We also acknowledge that any turbine-related mortalities or fish trapped in the intake do not compromise our fishery management objectives for the West Branch or the Ripogenus impoundment. In fact, smelt drift through the dam and power station is essential to maintain salmon growth in the river. Any attempts to reduce entrainment for other species could impact smelt drift and adversely influence our management plans for the river.

***Fish Passage/Invasive Species Discussion***

MDIFW is not requesting any changes to fish passage in either the Ripogenus Project or the Penobscot Mills Project. That said, MDIFW routinely considers the potential to increase the distribution of invasive fish in reviewing dam relicensing projects in Maine. Invasive fish are a serious threat to Maine's' wild and native fisheries. Once established, there are few options to mitigate or eliminate the resulting impacts, with consequences that permanently affect the ecosystem.

Both the State of Maine and the Federal government recognize the gravity of invasive species. The Nonindigenous Aquatic Nuisance Prevention and Control Act of 1990 was adopted primarily to prevent and control infestations of Zebra mussels in the Great Lakes. The act was expanded to include preventative measures for all invasive species. As part of this Act, states were directed to develop state-specific invasive species plans with input from the public.

In the 2002, the State of Maine developed an action plan for dealing with invasive species, including fish. The plan states in part:

> *"Consistent with Maine's traditional approach to addressing environmental problems, the goals of this plan are based on a hierarchy designed first to prevent problems, and then, if any should occur, to limit their extent and reduce their effects. Prevention carries a price tag, but it is the only possible way to avoid incurring much higher costs associated with the environmental, economic, and social disruptions that follow infestations of aquatic invasive organisms."*

The first goal of this plan is to prevent the new introductions wherever possible.

In January 2005, MDIFW confirmed the presence of northern pike, a designated invasive species, in Pushaw Lake. A lake management plan was developed with the main goal of preventing further spread of this invasive species as well as controlling the population in Pushaw Lake. The outlet of Pushaw Lake flows into the Penobscot River in Old Town, above the Milford-Old Town Dam. The plan states that *"Limiting northern pike passage through fishways at a number of dams on the Penobscot, Piscataquis and Passadumkeag Rivers is essential in limiting their movement through the drainage, and may be our last defense in excluding pike in the Upper Penobscot Watershed."*

Presidential Executive Order 13112, signed in February 1999, was created to control and minimize the impacts of invasive species by establishing an Invasive Species Council, and by establishing duties of Federal agencies whose actions affect the status of invasive species. Specifically, Section 2, Paragraph 3 states that Federal agencies shall not authorize, fund, or carry out actions that it believes are likely to cause or promote the introduction or spread of invasive species in the U.S. or elsewhere unless, pursuant to guidelines that it has prescribed, the agency has determined and made public its determination that the benefits of such actions clearly outweigh the potential harm caused by the invasive species; and that all feasible and prudent measures to minimize the risk of harm will be taken in conjunction with the actions. Note that the actions to be taken by Federal agencies must occur before authorizing, funding, and action.

The ecosystem in the Penobscot River drainage has seen significant changes since the last relicensing. Invasive species, including northern pike, black crappie, largemouth bass, and white catfish have been documented in the lower Penobscot drainage. Northern pike and largemouth bass are now well-established in Pushaw Lake, which drains into the Stillwater River. As a result, these two species have access to the mainstem of the Penobscot River above the dams in Milford and Orono. At some time in the future, they will likely move upstream as far as the East Millinocket Dam, which is the lowest dam of the Penobscot Mills project. MDIFW is concerned that allowing these species to gain upstream access will directly impact wild and native fisheries. We are also concerned that allowing these species to have access to the impoundments in the Project areas will create additional sources for anglers to relocate these invasive fish to waters outside of that which they could travel on their own. This activity has been well-documented in Maine in the Belgrade Lakes region where northern pike were illegally introduced in the 1970's. They have since spread throughout the lower Kennebec and Androscoggin drainages, as well as other drainages as a result of natural migration, dam removal, and unauthorized introductions.

Baxter State Park is a short distance from the Project area and is renowned for its wild and native brook trout waters. There are also many designated State Heritage Fish Waters that drain

directly into the West Branch drainage above the North Twin impoundment. State Heritage Fish Waters are native and wild brook trout lakes and ponds which represent unique, valuable, and irreplaceable ecological and angling resources. MDIFW recognizes the unrivaled historic and economic importance of Maine's wild and native brook trout resource and focuses on the conservation and protection of this uniquely valuable resource. MDIFW's primary intent for managing wild brook trout in lakes and ponds is the protection and conservation of these self-sustaining fisheries. Allowing fish passage into the North Twin impoundment would allow invasive fish to have access to other upstream waters including the Nahmakanta and Debsconeag systems, and the West Branch of the Penobscot River itself, which is a destination fishery for wild landlocked salmon and native brook trout.

The absence of fish passage in these project dams on the West Branch of the Penobscot represent the best opportunity to prevent the expansion of invasive fish in Maine and to protect the important wild and native freshwater game species upstream in the drainage.

***Ripogenus Project Operations Recommendations for Fisheries/Angling Enhancement***

1. To better understand lake level fluctuations at the Ripogenus impoundment, MDIFW requests that the Licensee provide daily lake elevations and daily minimum, mean, and maximum flows from Ripogenus Dam since the current license was issued.
2. MDIFW has concerns that even during low water years, the Licensee ran flows in excess of the required minimum flows. MDIFW observed on several occasions in the winter and summer of 2021 that the Licensee was indeed running in excess of 3,000 cfs when lower flows were required by the license; however, we do not know the frequency of these occurrences and whether they were necessary for downstream needs, and/or whether they significantly impacted lake elevations in the Ripogenus impoundment. We have received anecdotal reports from anglers on the West Branch that insect hatches are less frequent and less intense than in the past. As the literature is replete with examples of the detrimental impacts on the riverine fisheries and aquatic communities from rapid changes in flow, and that the literature indicates that flow changes of less than 25% per hour (ramping rate) can mitigate impacts from peaking power, we request flow records to evaluate the frequency of flow changes that exceed 25%.
3. Six angler sites were identified at McKay Station during the previous relicensing studies. When Brookfield purchased the Project, large areas around the power station were fenced off, eliminating most of the fishing sites. MDIFW believes there is now only one site available on the south side of the river (just upstream of the power station). We request Brookfield move this fencing to restore the historic angling sites at this location.
4. There were two fisheries enhancements projects completed under the current license: 1) the construction of the Holbrook Bypass channel, and 2) the release of 100 cfs into the Upper Gorge from July 1 – September 30. The Licensee has completed the required evaluation for the Holbrook Bypass and MDIFW concurs that this project has been successful. The Licensee and MDIFW have verified the presence of young wild salmon and brook trout in the channel. We simply request that the Licensee continue to operate and maintain the Holbrook Side Channel as outlined in the current license, Order approving recommendations of habitat improvement plan under Article 406, Issued February 20, 2003.

The purpose of the supplemental flow in the Upper Gorge was solely to provide fishing opportunities. Multiple sites were identified in previous studies that would provide additional fishing opportunities in the Upper Gorge. It was the intent of MDIFW that the flows in the Upper Gorge would originate from a deep gate and therefore provide a cool water attraction flow as adult salmon reached the upper river in July. However, the water is released from a sluice (surface) gate which is warm water. This water is warmer than the water passing through McKay Station into the river and is therefore ineffective as an attraction flow. We request Brookfield develop a plan to provide a 100 cfs flow from July 1 to September 30 into the Upper Gorge from below 45 feet (summer thermocline location) in the impoundment to fulfill the original intent of this mitigation and provide additional fishing opportunities.

5. MDIFW supports target lake elevations on the Ripogenus Impoundment that allow for angler use and access. We consider this to be a reasonable request and is commonplace on FERC-regulated impoundments throughout Maine, including waters upstream and downstream of the Ripogenus Project. The paper mills are no longer operational in Millinocket and East Millinocket, which should give the Licensee more flexibility to manage water in this integrated system. As we realize this is a complicated issue with competing needs downstream of the Ripogenus Dam, we recommend developing a Stakeholder Group with representation from all the interested parties, including the camp owners on the Ripogenus impoundment who were not involved with the previous relicensing process, to determine appropriate lake elevations during the recreational season and refine downstream flows as necessary. As noted previously in our comments, we view this as an opportunity to refine the current operation and minimize the unintended impacts, especially during drought conditions.

***Penobscot Mills Recommendations for Fisheries/Angling Enhancement***

1. Article 413 of the current license directs the Licensee to perform the May and September trout stocking in Millinocket Stream. Given increased angling pressure in the region, MDIFW recommends that this program continue for the duration of the new license.
2. To enhance public access opportunities, MDIFW requests that the Licensee establish a public launch in the East Millinocket impoundment. It is MDIFW's understanding that the Licensee has retained property easement/development rights along the impoundment shoreline, and now that the mill is no longer operational, we believe it should not be an issue to have private vehicles accessing former mill property. Final details need to be worked out, but MDIFW envisions a launch for small watercraft, similar to the Licensee-established boat launch below the North Twin Dam, along with associated parking for three to four vehicles with trailers and appropriate signage, would be sufficient for angling access between the East Millinocket Dam and the Dolby Dam, an approximately 1.75 mile stretch of the West Branch Penobscot River.

## Wildlife Study Requests

### Study Request 1: Assess the presence of Wood Turtles and Project effects on nesting habitat, nesting success, and overwintering habitat

1. The goal of this study is twofold: first, to confirm the presence of wood turtles (*Glyptemys insculpta*) in the Ripogenus and Penobscot Mills Project areas, and the West Branch of the Penobscot River downstream of the dams, and secondly to determine whether Project operations negatively impact wood turtles and whether operations could be adjusted to benefit both wood turtle nesting and overwintering habitat.

The initial objective is to determine if wood turtles are present within the portion of the West Branch that is influenced by Project operations. Wood turtles are present in the West Branch upstream of the Ripogenus Project area (Northeast carry TWP in West Branch and also Russell Stream), and presence seems likely elsewhere based on desktop analysis of aerial imagery, a recent cursory trip to the Project area by MDIFW staff, available habitat, and additional occurrences of the species, both confirmed and unverified, in the Project vicinity.

If wood turtle presence is confirmed, the study would transition into understanding the effects that Project operations have on both wood turtle nesting and overwintering habitats, and whether operations have affected the quality and availability of these habitats over time. The study would document wood turtle nesting and overwintering habitats within the Project effect areas and measuring what effect water flows and fluctuations have on wood turtle use of these habitats. The final objective is to apply the site-specific understanding of wood turtle habitat use and evaluate potential management actions that would benefit nesting habitat and nesting success, and overwintering habitat in the Ripogenus and Penobscot Mills Project areas and the West Branch downstream of the dams.

2. MDIFW is the natural resource agency responsible for managing wildlife resources along the West Branch of the Penobscot River. Wood turtles are designated as a State Species of Special Concern. A Species of Special Concern is any species of fish or wildlife that does not meet the criteria of an Endangered or Threatened species but is particularly vulnerable, and could easily become, an Endangered, Threatened, or Extirpated species due to restricted distribution, low or declining numbers, specialized habitat needs or limits, or other factors. Hydroelectric dams have been identified as a threat to wood turtles in Maine's 2015 State Wildlife Action Plan.

3. MDIFW is a cabinet-level agency of the State of Maine.

4. Wood turtles are facing range-wide declines and are listed as a Tier 1 Species of Special Concern in Maine. They are also designated as an "at risk species" by the USFWS and are currently under consideration for federal Endangered Species Act listing. Previous research in western Maine along the Dead River below the Flagstaff Project (FERC No. P-2612) by Compton (1999) determined that dams are a major threat to wood turtles because of flooding and degradation of nesting sites. Aerial imagery and a recent site visit indicate that suitable wood

turtle nesting and overwintering habitat likely exists downstream of the Ripogenus Dam and elsewhere.

Given both the potential for wood turtles to occur in the reaches of the West Branch below the dams, and within areas effected by Project operations, and the known effects dams have on wood turtles, a survey for wood turtles is warranted to determine the effects high flow releases have on wood turtles during their nesting season.

5. Intensive study of impacts to wood turtles from the Flagstaff Project determined that 25% of wood turtle nests failed as a result of high flows during nesting season (Compton 1999). If wood turtles are found in the Project areas, including in the West Branch downstream of the dams, Project operations should be assessed to determine the level of impact on wood turtle nesting habitat, nesting success, and overwintering habitat. A better understanding of the relationship between Project operations and turtle habitat availability and successful use of these habitats will help guide discussions to minimize or eliminate Project impacts on wood turtles should they be occurring.

6. Surveys should be conducted to determine wood turtle habitat and presence in early spring, prior to the start of wood turtle nesting. Survey methods outlined in Brown et. al. (2017) is recommended to confirm presence of wood turtles. If presence is confirmed, telemetry tags will be affixed to a sample of turtles, with actual numbers to be determined, that will be monitored for both nesting and overwintering locations. Nests will be monitored following similar methods outlined in Compton (1999). Nesting success relative to Project operations will be monitored to determine nesting success and measure effects from Project operations, including water flows, especially regarding planned and unplanned high flow release events that occur within the wood turtle nesting season.

Once nesting and overwintering habitats are documented, a review of existing habitat conditions should be compared with habitat conditions over time to evaluate potential changes in habitats. Of particular interest is whether flow regimes maintain open gravel bar habitat preferred by nesting wood turtles. MDIFW is willing to collaborate with the Licensee on this study. MDIFW would assist in various phases of the study including study design, scoping, and survey effort.

7. This type of study would require funding for 1-2 seasonal staff and their associated transportation. The project would begin operating after the spring snow melt and run as long as weather conditions allow to better document any overwintering sites. The first phase of the project would entail intensive turtle surveys, and if located and tagged, the project would shift to monitoring of tagged turtles and locating nesting and overwintering locations. Once all nests had been located, the final phase of fieldwork would involve monitoring of nesting success relative to water flow regimes.

Once nesting habitat is identified, a desktop analysis of habitat changes over time would be assessed through review of satellite imagery and would likely require several days of review and reporting to summarize findings.

A final report would summarize findings and review effects flow regimes have on nesting success and nesting habitat. The reporting phase would require two weeks of work for one

person. Researchers should also prepare and present a summary of the findings to Project stakeholders.

**Study Request 2: Exposed Aquatic Habitat Assessment**

1. The goal of this study is to quantify the total area of exposed aquatic substrate of all waterbodies comprising both the Ripogenus Project and Penobscot Mills Project. The assessment should consider exposed substrate, relative to the full pond elevation of each waterbody, during three scenarios:

- 10-year average annual drawdown for each waterbody
- low-water years for each waterbody, using 2021 water levels
- under maximum allowable drawdown for each waterbody

Additionally, we are requesting a quantitative assessment of exposed aquatic substrates in the downstream riverine ecosystems for each project. Analyses of downstream riverine ecosystems should also include both the "Back Channel" (mainstem West Branch downstream of Quakish Lake) and Millinocket Stream.

2. MDIFW is the natural resource agency responsible for managing fish and wildlife resources along the West Branch of the Penobscot River, with "wildlife" defined as all animals including insects and macroinvertebrates. As the life history of inland fish and many aquatic wildlife are closely tied to the stability and area of the near-shore littoral zone, MDIFW is concerned that some of these resources are negatively impacted by the frequency and extent of aquatic drawdown events on the West Branch of the Penobscot River. The macroinvertebrate community plays an important role in the composition of an aquatic ecosystem. Macroinvertebrates are a food source for the fishery and other aquatic resources that may be present.

3. MDIFW is a cabinet-level agency of the State of Maine.

4. Maine's 2015-2025 Wildlife Action Plan identifies 378 Species of Greatest Conservation Need (SGCN) within six major taxa groups, many of which are located or predicted to be in the Project area. The Plan also identifies the habitats in Maine needed by each SGCN, the greatest stressors affecting SGCN and their habitats, and some of the conservation actions that can be taken to reduce these stressors. Among state-listed species, MDIFW has confirmed the presence of: a) two State Threatened freshwater mussel species (and the potential for a third); b) State Special Concern pygmy snaketail dragonflies in the West Branch downstream of Ripogenus Dam; and c) State Special Concern bigmouth pondsnails in Millinocket Lake. A list of documented, modeled, and predicted SGCN aquatic or aquatic-associated invertebrate species in the Project areas includes:

| | | |
|---|---|---|
| 1 | *Aeshna juncea* | Sedge Darner |
| 2 | *Alasmidonta undulata* | Triangle Floater |
| 3 | *Alasmidonta varicosa* | Brook Floater |
| 5 | *Ameletus browni* | A Mayfly |
| 6 | *Anodonta implicata* | Alewife Floater |
| 7 | *Baetisca berneri* | A Mayfly |
| 8 | *Baetisca lacustris* | A Mayfly |
| 9 | *Baetisca rubescens* | A Mayfly |
| 10 | *Boloria frigga saga* | Frigga Fritillary |
| 11 | *Cicindela ancocisconensis* | White Mountain Tiger Beetle |
| 12 | *Cicindela marginipennis* | Cobblestone Tiger Beetle |
| 13 | *Enallagma carunculatum* | Tule Bluet |
| 14 | *Enallagma laterale* | New England Bluet |
| 15 | *Enallagma pictum* | Scarlet Bluet |
| 16 | *Epeorus frisoni* | Roaring Brook Mayfly |
| 17 | *Lampsilis cariosa* | Yellow Lampmussel |
| 18 | *Lanthus vernalis* | Southern Pygmy Clubtail |
| 19 | *Leptodea ochracea* | Tidewater Mucket |
| 20 | *Leucorrhinia patricia* | Canada Whiteface |
| 21 | *Lycaena dorcas claytoni* | Clayton's Copper |
| 22 | *Margaritifera margaritifera* | Eastern Pearlshell |
| 23 | *Metretopus borealis* | A Mayfly |
| 24 | *Ophiogomphus colubrinus* | Boreal Snaketail |
| 25 | *Ophiogomphus howei* | Pygmy Snaketail |
| 26 | *Papilio brevicauda gaspeensis* | Short-tailed Swallowtail |
| 27 | *Parameletus midas* | A Mayfly |
| 28 | *Procloeon ozburni* | A Mayfly |
| 29 | *Rhithrogena undulata* | A Mayfly |
| 30 | *Siphlonisca aerodromia* | Tomah Mayfly |
| 31 | *Siphlonurus barbaroides* | A Mayfly |
| 32 | *Siphlonurus barbarus* | A Mayfly |
| 33 | *Siphlonurus demaryi* | A Mayfly |
| 34 | *Siphlonurus securifer* | A Mayfly |
| 35 | *Somatochlora brevicincta* | Quebec Emerald |
| 36 | *Stagnicola mighelsi* | Bigmouth Pondsnail |
| 37 | *Vertigo paradoxa* | Mystery Vertigo |

Species listed under Maine's Endangered Species Act (MESA, 12 M.R.S §12801 et. seq.) are afforded special protection against activities that may cause "take" (kill or cause death), "harassment" (create injury or significantly disrupt normal behavior patterns), and other adverse actions. These prohibitions encompass both negligent and intentional acts. A Species of Special Concern is any species of fish or wildlife that does not meet the criteria of an Endangered or Threatened species but is particularly vulnerable, and could easily become, an endangered, threatened, or extirpated species due to restricted distribution, low or declining numbers, specialized habitat needs or limits, or other factors.

Given both the known and predicted occurrences of these numerous at-risk aquatic or aquatic-associated invertebrate species, MDIFW wants to better understand the amount of aquatic habitat that will be potentially impacted, both from actual average annual and maximum drawdowns and riverine water level fluctuations, as well as what is allowed and proposed for the new license.

5. As each of the Threatened, Special Concern, and SGCN species is completely dependent upon suitable aquatic habitat for their life history requirements, water level fluctuations in both lacustrine and riverine environments have the potential to adversely impact these species.

6. Evaluations of drawdown zones and assessments of riverine areas subjected to flow variations are commonly requested for hydropower project relicensing. This study recommendation may parallel other agency study requests.

7. MDIFW asserts that the level of cost and effort is commensurate given the historical, current, and proposed operations for each Project. While near accuracy is of the utmost importance, MDIFW mostly envisions that a desktop, GIS-based exercise will be sufficient for completing the study. Once elevations for the 10-year average, low-water year (using the lowest 2021 elevation), and maximum allowable drawdown elevation under the current and proposed license are identified, a desktop analysis which results in quantitative amounts of substrate exposed for each waterbody, including a combined cumulative total, under each scenario should be reasonably attainable. As part of this assessment, inclusion of any aerial imagery existing photographs might prove instructive. The results should also document the frequency, length, and timing of drawdowns and downstream flow fluctuations, as these can exacerbate or amplify impacts of area exposed. We estimate that this effort would likely require several days of review and reporting to summarize findings.

**Study Request 3: Common Loon Management Plan Assessment—Ripogenus Project**

1. The goal of this study is to evaluate the Licensee's Common Loon Management Plan (Plan) at the Ripogenus Project. Specific objectives of this request are to:

- Assess use of rafts by loons at the Ripogenus impoundment
- Evaluate loon productivity under the Plan
- Determine if Project operations, particularly during low water years, are impacting loon productivity and if new strategies need to be incorporated into the Plan

2. Maine is home to 75% of the territorial pairs of loons in New England and New York, making it the stronghold for the northeast breeding population. Thus, despite the common loon's relatively stable and secure population within the state, Maine holds a high responsibility in the northeastern United States for the species' continued conservation.

MDIFW is interested in better understanding the effectiveness of the Plan, and whether loon productivity is being impacted, particularly during lower water years. This study request is consistent with MDIFW's goal of ensuring that wildlife and aquatic resources in the State of Maine are maintained and perpetuated for their intrinsic and ecological values, for their economic contribution, and for their recreational, scientific and educational use by the people of

the State. Furthermore, the common loon is identified as a Priority 2 Species of Greatest Conservation Need by MDIFW's Comprehensive Wildlife Conservation Strategy, also known as Maine's State Wildlife Action Plan (MDIFW 2015).

This study is consistent with USFWS' re-licensing goals to evaluate the need for protection, mitigation and enhancement measures necessary to meet state and federal fish and wildlife objectives; to conserve, protect and enhance the habitats for fish, wildlife and plants that continue to be affected by the Project; and to ensure that the public is afforded the opportunity for recreation on Project lands, which include but are not limited to fishing, hunting, bird watching, and other forms of outdoor recreation.

3. MDIFW is a cabinet level agency of the State of Maine.

4. According to Table 4.6-1 of the PAD, the Licensee began deploying artificial nesting platforms for loons and "other aquatic birds" in the Ripogenus impoundment in 2000. The Licensee monitored the loon nesting habitat and success from 1998 through 2010, and although monitoring was discontinued in 2010, the Licensee continues to deploy the platforms on Ripogenus impoundment and increased the number of platforms beginning in 2011.

However, limited details are provided in the PAD, and it is unclear to MDIFW how successful the loon management program is at the Ripogenus impoundment. Details on productivity of common loons there are unknown. This is especially critical given that recent low water years have likely left some rafts stranded, making them unusable to resident nesting loons. Also unknown is whether rafts are actively maintained on an annual basis, and whether rafts are being stranded and abandoned under low water conditions, thereby rendering the existing placement of rafts ineffective.

5. The effects of dam operations on loon population are well known, as evidenced by the Licensee's Management Plan. The results of this study request will help determine if additional mitigation measures are necessary, and what specific measures may be needed, in order to prevent negative impacts to loon productivity within the Project area.

6. Standard survey methods developed by the Loon Preservation Committee in New Hampshire and the BioDiversity Research Institute, were adopted by the Northeast Loon Study Working Group that includes weekly surveys by boat from mid-May until the end of July (Taylor and Evers 2009). Bi-weekly surveys are often needed to monitor chick survival. Nest searching may require walking portions of shoreline to determine if natural nesting is being attempted. Data collected during surveys, depending on the timing within the loon nesting cycle, should include: number of territorial pairs, delineation of territory boundaries defended by those pairs, number and location of nesting attempts differentiated between natural sites and artificial sites; determining causes of nest failure and/or raft abandonment, observations of clutch size and number of chicks hatched, and documenting chick survival.

7. Field work will be required to collect data on presence/absence of territorial loon pairs, nesting attempts, and to determine causes of nest failures, particularly at artificial sites. MDIFW envisions at least three years of field work by qualified loon biologists to determine the

effectiveness of the Plan, and whether modifications of the Plan need to occur to benefit this SGCN species for the duration of the new license.

## Study Request 4: Common Loon Productivity Assessment—Penobscot Mills Project

1. The goals of this study are to evaluate the common loon nesting success within the Penobscot Mills Project area, determine if operations of the Project are affecting loon productivity within the study area, and assess causes of nest failure to determine if these failures are influenced by Project operations.

2. Maine is home to 75% of the territorial pairs of loons in New England and New York, making it the stronghold for the northeast breeding population. Thus, despite the common loon's relatively stable and secure population within the state, Maine holds a high responsibility in the Northeastern United States for the species' continued conservation.

MDIFW is interested in better understanding what effects, if any, the current Penobscot Mills Project operations have on common loon productivity. Specifically:

- Millinocket Lake: current and proposed Project operations maintain the Millinocket Lake reservoir level between elevations 470 and 480 feet at the Millinocket Lake Storage Development while providing water to maintain North Twin impoundment levels.
- North Twin: the Licensee maintains the North Twin impoundment at a relatively stable level from May 1 - August 22 annually ("relatively stable level" is not defined).

3. MDIFW is a cabinet level agency of the State of Maine.

4. As a condition of the existing license, in 2000 the Licensee deployed artificial nesting platforms for loons in Millinocket Lake. The Licensee monitored the loon nesting habitat and success from 1998 through 2010, and the monitoring indicated that loons successfully nested naturally on Millinocket Lake without artificial nest platforms. Subsequently, the Licensee discontinued deployment of nesting platforms and the associated monitoring and report in 2011.

It has been well documented that water level changes as little as 0.5 vertical feet up or 1 vertical foot down occurring within a 28-day period can significantly impact the success of non-floating loon nests (Fair et al. 1999). Due to their physical inability to walk about on land, common loons build their nests directly adjacent to the water's edge; however, the placement of nests

immediate to the shore makes them extremely susceptible to fluctuations in water level. Nests may be inundated by increasing water levels or stranded by decreasing water levels; both situations enhance predation and affect hatching rates (Fair 1979). Water level management was shown to cause 60-70% of nest failure for loons on three lakes in Voyageur's National Park in Minnesota (Reiser 1988). Loons whose territories are characterized by fluctuating water levels may not hatch a sufficient number of young to sustain populations, resulting in an ecological trap (DeSorbo et al. 2007).

It has been 10 years since common loon productivity has been assessed at the Penobscot Mills Project, and since that time there have been at least three low water years (2016, 2020, 2021). Given the growing realization of changing weather patterns associated with climate change, and given the proposed allowable magnitude of lake level fluctuations requested for the new License, MDIFW believes that a re-assessment of common loon productivity is warranted.

5. The potential effects of dam operations on the local loon population are outlined above. The study results will help determine if additional mitigation measures are necessary, and what specific measures may be needed, in order to prevent negative impacts to loon productivity within the Project area.

6. Standard survey methods developed by the Loon Preservation Committee in New Hampshire, the BioDiversity Research Institute, and adopted by the Northeast Loon Study Working Group include weekly surveys by boat beginning in mid- to late- May and continuing through July (Taylor and Evers 2009). Bi-weekly surveys are often needed to monitor chick survival. Nest searching may require walking portions of shoreline. Data collected during surveys, depending on the timing within the loon nesting cycle, should include: number of territorial pairs, delineation of territory boundaries defended by those pairs, number and location of nesting attempts, determining causes of nest failure, observations of clutch size and number of chicks hatched, and documenting chick survival.

7. Field work will be required to collect data on presence/absence of territorial loon pairs. If territorial pairs exist, then at least two additional years of field work will be needed to determine fledging rates and causes of nest failure. If fledging rates are lower than 0.48 chicks per territorial pair, which is needed to support a stable and sustaining population, then annual monitoring and possibly a raft management plan or more stable water levels may be necessary.

**Study Request 5: Marsh Bird Surveys—Ripogenus Project**

1. The goal of this study is to determine if any rare marsh-nesting birds (least bittern (*Ixobrychus exilis*), sedge wren (*Cistothorus platensis*), black tern (*Chlidonias niger*), common gallinule (*Gallinula galeata*), and American coot (*Fulica americana*)) occur in the study area, and if operation of the Ripogenus Project is potentially affecting their productivity. This study will consist of two phases:

   a. A desktop study of emergent marsh wetlands associated with the Ripogenus Project will be conducted based on review of aerial photographs and mapped inland waterfowl and wading bird habitats. The desktop study will help determine wetlands where marsh bird surveys should be conducted.

   b. Once suitable habitat has been identified, the Standardized North American Marsh Bird Monitoring Protocol (Conway 2009) will be used to survey for rare marsh birds. Based on the large size of the Project, locations and suitability of potential habitat for these targeted marsh-nesting bird species must be assessed with a field visit prior to establishment of survey locations to maximize the efficiency and scientific validity of the surveys.

2. MDIFW is responsible for protecting wildlife resources and is interested in better understanding the presence and distribution of rare marsh birds in the wetlands at the Ripogenus impoundment. The least bittern, sedge wren, and black tern are listed as Endangered Species in Maine, the common gallinule is listed as a State Threatened Species, and the American coot is listed as a Species of Special Concern in Maine. Species listed under Maine's Endangered Species Act (MESA, 12 M.R.S §12801 et. seq.) are afforded special protection against activities that may cause "take" (kill or cause death), "harassment" (create injury or significantly disrupt normal behavior patterns), and other adverse actions. These prohibitions encompass both negligent and intentional acts. A Species of Special Concern is any species of fish or wildlife that does not meet the criteria of an Endangered or Threatened species but is particularly vulnerable, and could easily become, an endangered, threatened, or extirpated species due to

restricted distribution, low or declining numbers, specialized habitat needs or limits, or other factors.

3. MDIFW is a cabinet level agency of the State of Maine.

4. There is limited knowledge regarding the status and trends of several species of marsh birds in Maine, and throughout much of North America. Many marsh bird populations in North America appear to be declining (Tate 1986, Eddleman et al. 1988, Conway 2009), and there is anecdotal evidence of declines for some species in Maine. Many historic breeding sites are no longer occupied, thus survey of potential new sites is extremely important for understanding each species' status within the state.

Based on field surveys conducted for the previous relicensing in the late 1980s and early 1990s, several categories of wetlands were identified at the Ripogenus Project, including: 1) alder thickets; 2) conifer swamp/wet forest; 3) wet meadow/emergent marsh and wet meadow/open water; and 4) open bog/wet meadow. According to the PAD, there are 358.8 acres of palustrine emergent wetland and 790.1 acres of palustrine scrub-shrub wetland at the Ripogenus Project; these habitats should be the focus for marsh bird surveys.

Least bitterns breed in freshwater marshes and usually nest in dense stands of cattails, bulrushes or similar growth about a foot above the water and near open water. Occasionally they nest in a low bush or tree or on the old nest of another bird. Least bitterns generally nest singly but several adjacent pairs may occur in suitable areas (Baicich and Harrison 2005).

Sedge wrens breed in wet meadows or drier areas of marshes and bogs dominated by grasses and sedges. The birds nest low in grasses, sedges, or similar herbaceous species, very near the ground or over shallow water. Nests are well hidden in the bases or growing vegetation but rarely can be 1-2 feet up in the vegetation (Baicich and Harrison 2005).

Black terns breed on shallow, still water, in freshwater or brackish areas, that are often characterized by reedy vegetation and swampy marshes. The birds can create a variety of nests including: as a heap of floating vegetation in the water, anchored by growing plants, or on mats of floating aquatic vegetation or heaps of fallen herbaceous vegetation; on old muskrat houses, old grebe or coot nests, or floating driftwood; or on firm ground among marshy herbaceous vegetation. Black terns generally nest in small colonies (Baicich and Harrison 2005).

Common gallinules breed at the edge of fresh water including lakes, rivers, small marshes, and ditches. The birds generally nest on the ground by water, or among plants in water, but sometimes they nest above ground in thick shrubs or in large old nests of other birds in trees. The birds may build additional nests (brood platforms) in territory, especially in marshy sites and use the platforms for brooding young (Baicich and Harrison 2005).

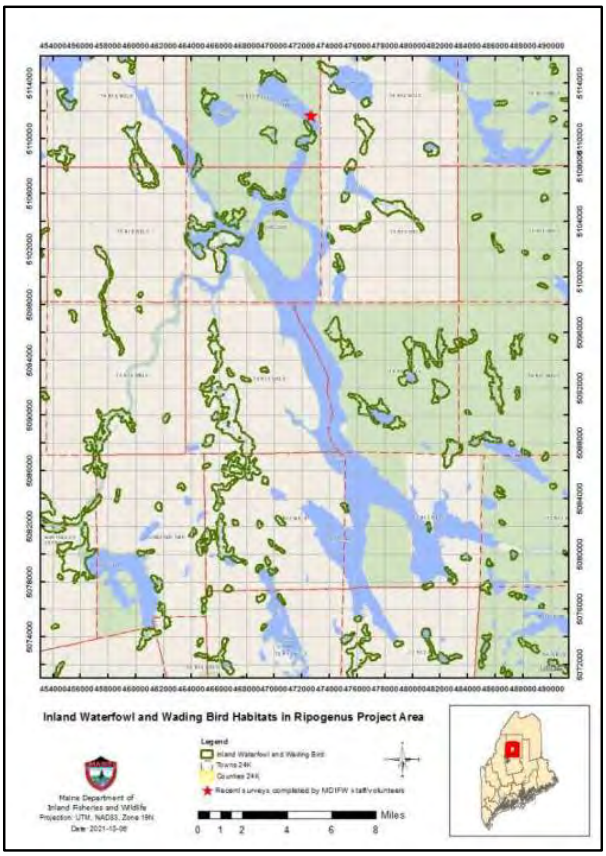
American coots breed in freshwater wetlands containing: 1) heavy stands of emergent aquatic vegetation along at least some portion of the shoreline, and 2) some standing water within the vegetation (interspersion). Nests are typically built over water on floating platforms and associated with dense stands of living or dead vegetation such as reeds, cattails, bulrushes,

sedges, and grasses. Occasionally, the nest may be built on the edge of a stand of vegetation, where it is clearly visible (Brisbin et al. 2002).

5. The five species of marsh-nesting birds identified could potentially be positively or negatively affected by water levels, water quality, invasive aquatic plants, and the wake from recreational watercraft. Least bitterns, black terns, common gallinules, and American coots all prefer hemi-marsh conditions, which is a 50:50 ratio of open water to emergent marsh habitat. They nest very close to the water's surface, thus water level fluctuations up or down can flood nests or make them more vulnerable to predation. They rely primarily on aquatic invertebrates for food, which are directly influenced by water quality.

The extent and locations of emergent marsh habitat in the Ripogenus Project will first be assessed to determine sites for marsh bird surveys. If rare marsh birds are detected within the Project, additional studies or mitigation measures may be warranted to protect and conserve the species and occupied habitats.

6. The desktop study of emergent marsh wetlands associated with the Ripogenus Project will identify emergent, scrub-shrub, and wet meadow habitat through photo interpretation of aerial photographs and review of mapped inland waterfowl and wading bird habitats, and identify potentially suitable nesting habitat associated with the Ripogenus Project for these five marsh-nesting bird species.



As requested by MDIFW, and consistent with generally accepted scientific practices, the Standardized North American Marsh Bird Monitoring Protocol (Conway 2009) will be used if suitable habitat is identified and marsh-nesting bird surveys are deemed necessary in the Ripogenus Project. The protocol includes in its methods, field broadcast survey at fixed points approximately 400 meters apart within marsh habitat. Based on the large size of the Ripogenus Project, locations and suitability of potential habitat for these targeted marsh-nesting bird species must be assessed prior to establishment of survey locations to maximize the efficiency and scientific validity of the surveys.

The survey will be conducted by playing call-back audio clips in habitat for least bittern, common gallinule, American coot, and sedge wren. Call playback is not used for black terns, but their presence and behaviors should be noted. Survey points will be spaced at least 400 m apart, or approximately one point per 12 ha at a minimum and located along the perimeter of marsh areas that are practical to access via boat so that site disturbance is minimized. Final survey locations will be determined based on field conditions and extent of suitable habitat. The surveys will begin as soon after sunrise as is safely practicable and continue up to 4 hours after sunrise. One survey will be conducted per each 15-day survey period. Survey periods are May 15 - May 31, June 1 – June 14, June 15 – June 30.

7. The level of effort and cost is commensurate with a Project the size of the Ripogenus Project and the likely license term. Given the size of the impoundment and its associated IWWHs, as well as the remote location, the field data collection component of this study will require substantial time and effort. However, the duration of the breeding season is relatively short. Data analysis should be straightforward and require low to moderate effort. MDIFW envisions two qualified biologists with experience conducting marsh bird surveys in Maine to accomplish

this study. The first task will be to identify locations of suitable survey locations. Three surveys at each site will be conducted between May 15 and June 30 (see survey windows above), followed by an estimated two days of report preparation.

MDIFW staff and volunteers have recently conducted marsh bird surveys at select wetlands as part of the Maine Bird Atlas inventory efforts (see Figure below). These sites will not need to be included in this study and MDIFW is willing to share results if Licensee is interested in those data.

**Study Request 6: Marsh Bird Surveys—Penobscot Mills Project**

1. The goal of this study is to determine if any rare marsh-nesting birds (least bittern (*Ixobrychus exilis*), sedge wren (*Cistothorus platensis*), black tern (*Chlidonias niger*), common gallinule (*Gallinula galeata*), and American coot (*Fulica americana*)) occur in the study area, and if operation of the Penobscot Mills Project is potentially affecting their productivity. This study will consist of two phases:

a. A desktop study of emergent marsh wetlands associated with the Penobscot Mills Project will be conducted based on review of aerial photographs and mapped inland waterfowl and wading bird habitats. The desktop study will help determine wetlands where marsh bird surveys should be conducted.

b. Once suitable habitat has been identified, the Standardized North American Marsh Bird Monitoring Protocol (Conway 2009) will be used to survey for rare marsh birds. Based on the large size of the Project, locations and suitability of potential habitat for these targeted marsh-nesting bird species must be assessed with a field visit prior to establishment of survey locations to maximize the efficiency and scientific validity of the surveys.

2. MDIFW is responsible for protecting wildlife resources and is interested in better understanding the presence and distribution of rare marsh birds in the wetlands at the Penobscot Mills Project. The least bittern, sedge wren, and black tern are listed as Endangered Species in Maine, the common gallinule is listed as a State Threatened Species, and the American coot is listed as a Species of Special Concern in Maine. Species listed under Maine's Endangered Species Act (MESA, 12 M.R.S §12801 et. seq.) are afforded special protection against activities that may cause "take" (kill or cause death), "harassment" (create injury or significantly disrupt normal behavior patterns), and other adverse actions. These prohibitions encompass both negligent and intentional acts. A Species of Special Concern is any species of fish or wildlife that does not meet the criteria of an Endangered or Threatened species but is particularly vulnerable, and could easily become, an endangered, threatened, or extirpated species due to restricted distribution, low or declining numbers, specialized habitat needs or limits, or other factors.

3. MDIFW is a cabinet level agency of the State of Maine.

4. There is limited knowledge regarding the status and trends of several species of marsh birds in Maine, and throughout much of North America. Many marsh bird populations in North America appear to be declining (Tate 1986, Eddleman et al. 1988, Conway 2009), and there is anecdotal evidence of declines for some species in Maine. Many historic breeding sites are no longer occupied, thus survey of potential new sites is extremely important for understanding each species' status within the state.

Based on field surveys conducted for the previous relicensing in the late 1980s and early 1990s, several categories of wetlands were identified at the Penobscot Mills Project, including: 1) alder thickets; 2) conifer swamp/wet forest; 3) wet meadow/emergent marsh and wet meadow/open water; 4) open bog/wet meadow; and 5) deep marsh/aquatic bed. According to the Pre-Application Document, there are 306.2 acres of palustrine emergent wetland and 379.9 acres of palustrine scrub-shrub wetland at the Penobscot Mills Project; these habitats should be the focus for marsh bird surveys.

Least bitterns breed in freshwater marshes and usually nest in dense stands of cattails, bulrushes or similar growth about a foot above the water and near open water. Occasionally they nest in a low bush or tree or on the old nest of another bird. Least bitterns generally nest singly but several adjacent pairs may occur in suitable areas (Baicich and Harrison 2005).

Sedge wrens breed in wet meadows or drier areas of marshes and bogs dominated by grasses and sedges. The birds nest low in grasses, sedges, or similar herbaceous species, very near the ground or over shallow water. Nests are well hidden in the bases or growing vegetation but rarely can be 1-2 feet up in the vegetation (Baicich and Harrison 2005).

Black terns breed on shallow, still water, in freshwater or brackish areas, that are often characterized by reedy vegetation and swampy marshes. The birds can create a variety of nests including: as a heap of floating vegetation in the water, anchored by growing plants, or on mats of floating aquatic vegetation or heaps of fallen herbaceous vegetation; on old muskrat houses, old grebe or coot nests, or floating driftwood; or on firm ground among marshy herbaceous vegetation. Black terns generally nest in small colonies (Baicich and Harrison 2005).

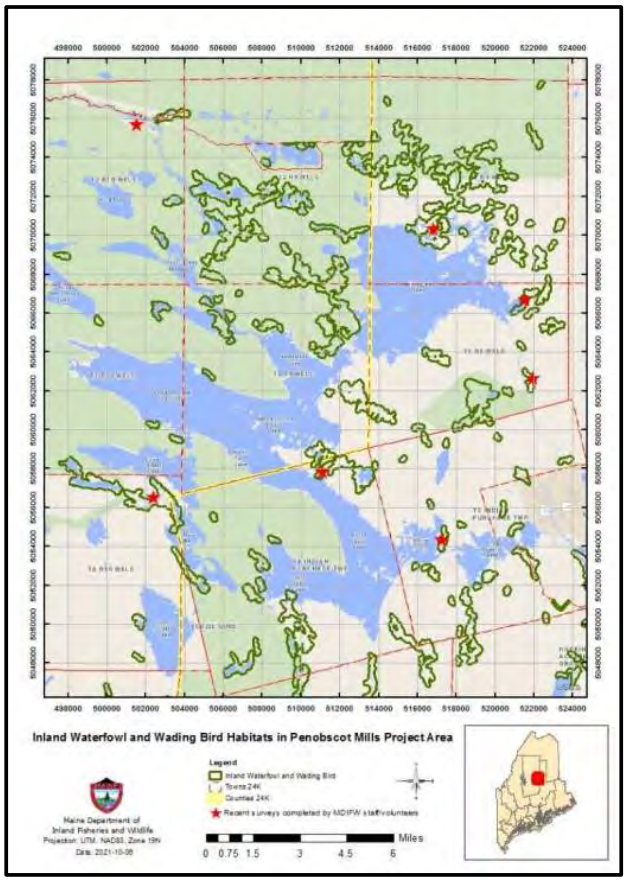
Common gallinules breed at the edge of fresh water including lakes, rivers, small marshes, and ditches. The birds generally nest on the ground by water, or among plants in water, but sometimes they nest above ground in thick shrubs or in large old nests of other birds in trees. The birds may build additional nests (brood platforms) in territory, especially in marshy sites and use the platforms for brooding young (Baicich and Harrison 2005).

American coots breed in freshwater wetlands containing: 1) heavy stands of emergent aquatic vegetation along at least some portion of the shoreline, and 2) some standing water within the vegetation (interspersion). Nests are typically built over water on floating platforms and associated with dense stands of living or dead vegetation such as reeds, cattails, bulrushes, sedges, and grasses. Occasionally, the nest may be built on the edge of a stand of vegetation, where it is clearly visible (Brisbin et al. 2002).

5. The five species of marsh-nesting birds identified could potentially be positively or negatively affected by water levels, water quality, invasive aquatic plants, and the wake from recreational

watercraft. Least bitterns, black terns, common gallinules, and American coots all prefer hemi-marsh conditions, which is a 50:50 ratio of open water to emergent marsh habitat. They nest very close to the water's surface, thus water level fluctuations up or down can flood nests or make them more vulnerable to predation. They rely primarily on aquatic invertebrates for food, which are directly influenced by water quality.

The extent and locations of emergent marsh habitat in the Penobscot Mills Project will first be assessed to determine sites for marsh bird surveys. If rare marsh birds are detected within the Project, additional studies or mitigation measures may be warranted to protect and conserve the species and occupied habitats.



6. The desktop study of emergent marsh wetlands associated with the Penobscot Mills Project will identify emergent, scrub-shrub, and wet meadow habitat through photo interpretation of aerial photographs and review of mapped inland waterfowl and wading bird habitats, and identify potentially suitable nesting habitat associated with the Penobscot Mills Project for these five marsh-nesting bird species.

As requested by MDIFW, and consistent with generally accepted scientific practices, the Standardized North American Marsh Bird Monitoring Protocol (Conway 2009) will be used if suitable habitat is identified and marsh-nesting bird surveys are deemed necessary in the Penobscot Mills Project. The protocol includes in its methods, field broadcast survey at fixed points approximately 400 meters apart within marsh habitat. Based on the large size of the Penobscot Mills Project, locations and suitability of potential habitat for these targeted marsh-nesting bird species must be assessed prior to establishment of survey locations to maximize the efficiency and scientific validity of the surveys.

The survey will be conducted by playing call-back audio clips in habitat for least bittern, common gallinule, American coot, and sedge wren. Call playback is not used for black terns, but their presence and behaviors should be noted. Survey points will be spaced at least 400 m apart, or approximately one point per 12 ha at a minimum and located along the perimeter of marsh areas that are practical to access via boat so that site disturbance is minimized. Final survey locations will be determined based on field conditions and extent of suitable habitat. The surveys will begin as soon after sunrise as is safely practicable and continue up to 4 hours after sunrise. One survey will be conducted per each 15-day survey period. Survey periods are May 15 - May 31, June 1 – June 14, June 15 – June 30.

7. The level of effort and cost is commensurate with a Project the size of the Penobscot Mills Project and the likely license term. Given the size of the impoundment and its associated IWWHs, as well as the remote location, the field data collection component of this study will require substantial time and effort. However, the duration of the breeding season is relatively short. Data analysis should be straightforward and require low to moderate effort. MDIFW envisions two qualified biologists with experience conducting marsh bird surveys in Maine to accomplish this study. The first task will be to identify locations of suitable survey locations. Three surveys at each site will be conducted between May 15 and June 30 (see survey windows above), followed by an estimated two days of report preparation.

MDIFW staff and volunteers have recently conducted marsh bird surveys at select wetlands as part of the Maine Bird Atlas inventory efforts (see Figure below). These sites will not need to be included in this study and MDIFW is willing to share results if Licensee is interested in those data.

**Study Request 7: Furbearer Survey—Ripogenus Project**

1. The goals of this study are as follows:

- Assess the relative abundance of muskrats and beavers at the Ripogenus Project by comparing with a natural reference (control) location of comparable size and shoreline characteristics (wetlands)
- Assess muskrat food availability throughout the year (e.g., cattail and bulrush)
- Determine overwinter survival and cause-specific mortality rates of muskrats and beavers
- Measure hydrology characteristics (water flows and depths) in areas of suitable habitat
- Determine use and movements of muskrats and beavers at the Ripogenus impoundment

2. MDIFW oversees the management of all furbearers across the State of Maine, and there is concern for reduced numbers of muskrats related to Project drawdowns. Since muskrats are not currently required to be tagged by trappers, we have little knowledge about the current status and population trends of this species. The majority of information that we receive about the muskrat population is gleaned from mandatory trapper surveys. The 2020-2030 Furbearer Management Plan aims to maintain healthy, abundant muskrat populations in Maine. Several important research and monitoring strategies have been identified, including developing methods to monitor the muskrat population and contributing to a regional study on the status and limiting factors for muskrats. Similarly, beavers depend on stable water levels and may be negatively impacted by large water fluctuations due to changes in access to food and houses. Many wildlife species benefit from beavers, including muskrats, so studying beaver populations in different wetland types is useful for understanding how drawdowns can impact overall biodiversity.

3. MDIFW is a cabinet level agency of the State of Maine.

4. Muskrat are culturally important to Native American tribes and are one of the most popular aquatic furbearer species to trap in the United States. Muskrat have traditionally been one of Maine's most sought-after furbearers due to their relative abundance, ease of harvest, and historic value. Muskrats have been identified as a Priority 3 Species of Greatest Conservation Need (SGCN) in Maine's Wildlife Action Plan due to their cultural significance to Native tribes and relatively recent population changes in the Northeast.

Beavers and muskrats require a permanent source of still or low-velocity water with ample emergent vegetation for forage and hiding cover. Muskrat generally do not store large quantities of food for the winter and must forage under the ice or on underground plants to survive the cold winter months. In northern areas like Maine, this means water levels must be deep enough to prevent complete freezing. Additionally, due to the structure and relative proximity of houses or pushups to water level, wetlands and waterbodies that have fluctuating,

or high seasonal levels tend to have relatively low muskrat or beaver densities. Extreme water level changes resulting from dams, precipitation, or drought events can negatively influence muskrat and beaver populations. Although muskrats are still common, there is evidence that their populations in the United States may be declining (Ahlers and Heske 2017). Perceived muskrat declines have not been linked solely to one issue, but to a compounding number of ecological and social factors. Environmental factors can alter available habitat and food, reproductive success, and mortality, all of which dictate regional muskrat population numbers. Loss of wetlands, increased predation, changing climate conditions, and disease may also have contributed to the declines. Project operations and perceived impacts on the preferred habitats of both muskrats and beavers warrant further study.

5. While the effects of dam operations, especially lake drawdowns, are well known on adjacent wetlands and near-water breeding birds, information regarding impacts of drawdowns to aquatic furbearers are not as well known. Some limited studies assessing the impacts of project drawdowns have been conducted elsewhere in Maine (e.g. Flagstaff and Indian Pond Projects), but the magnitude and duration of annual drawdowns, shallower bathymetry, and differences in site-specific shoreline characteristics of the Ripogenus impoundment make meaningful comparisons difficult.

6. MDIFW envisions a two-phased approach to this study request, with actual survey methodology to be finalized with the Licensee. Phase 1 would involve a survey of the Ripogenus Project area in the spring with emphasis on backwaters, inlets, outlets, and other wetland areas with suitable muskrat and beaver habitat. A total count of all muskrat houses, beaver lodges and food caches, and state of use (i.e. active, inactive) would be collected, and the location of each site collected via GPS. This survey would be repeated again in mid-summer, and any new activity would be documented, and locations of new activity captured via GPS. A third survey would occur with the late fall, at the onset of the icing, with observations of activity, states of use, and any new locations collected. Representative photographs of all sites will also be collected.

Concurrently, the Licensee will conduct similar surveys at a mutually agreed-upon natural reference lake(s).

Should Phase 1 surveys prove inconclusive, Phase 2 would generally follow Matykiewicz et al. 2021: a minimum of 25 muskrats and 10 beavers will be live-captured in wetland complexes during the subsequent summer field season and radio-tagged. Tagged animals will be monitored bi-monthly for the remainder of the summer and fall, and overwinter, to determine movements and document any relocations due to changing water levels, house or lodge abandonment, or causes of mortality.

7. Given the cultural and economic importance of aquatic furbearers, the level of effort and cost is commensurate with a Project the size of the Ripogenus Project and the likely license term. Given the size of the impoundment and its associated IWWHs, as well as the remote location, the field data collection component of this study will require substantial time and effort. Phase 1 field work and data analyses/reporting will take an entire field season; if Phase 2 is necessary, giving the proposed tagging and monitoring it is expected that moderate to high effort will be necessary.

## Fisheries Study Requests

### Study Request 8: Landlocked Salmon Habitat Use/Spawning Study—Penobscot Mills Project

1. This study will document the seasonal movement of landlocked salmon in the North Twin impoundment area (includes Ambajejus, Pemadumcook, North Twin, South Twin, and Elbow Lakes) as well as identify salmon spawning areas.

Objectives:

- Identify landlocked salmon spawning areas within the North Twin impoundment, and determine effects of Project drawdowns on spawning
- Determine the effects of annual Project drawdowns on the movement and behaviors of landlocked salmon in the impoundment
- Track seasonal movements and behaviors of landlocked salmon (within and between the five connected lakes) via radiotelemetry
- Assess tributary access and conduct tributary redd counts utilizing information obtained from tagged salmon movements
- Collection of biometric data to characterize landlocked salmon population dynamics

This study is being requested by MDIFW because currently data is lacking documenting the exact locations of spawning for landlocked salmon at the North Twin impoundment area. It is conventional thought salmon use larger tributaries of North Twin for spawning, particularly Nahmakanta Stream (Pemadumcook Lake) and the West Branch Penobscot River (Ambajejus Lake inlet). However, the North Twin impoundment is nearly 18,000 acres with numerous smaller tributaries in the impoundment which contain documented spawning habitat, yet it is unknown if salmon have the ability to access these tributaries for spawning.

2. MDIFW is the State Agency responsible for managing the inland fishery resources in Maine. The lakes within the North Twin impoundment are managed primarily for brook trout, landlocked salmon, lake trout, and rainbow smelt. Populations of these species are maintained through a combination of annual stocking (brook trout), semi-annual stocking (lake trout), and natural reproduction (landlocked salmon).

3. MDIFW is a cabinet-level agency of the State of Maine.

4. The North Twin Development operates as a store-and-release facility. From August 22 to October 15, the impoundment is maintained above elevation 488.42 feet (within 3.5 feet from normal full pond elevation). From October 15 to the start of the freshet, the impoundment elevation is gradually reduced to a lower target elevation of 479.42 (12 feet from normal full pond elevation) to provide storage for winter thaw and spring flows. MDIFW is not aware of any previous studies or data summaries focused on landlocked salmon movement and spawning habitat/tributary use as related to the North Twin impoundment in particular, nor the Penobscot Mills Project in general. This information would be invaluable to the Department's efforts of managing a (in recent years) naturally reproducing population of landlocked salmon to maintain a quality fishery in the nearly 18,000-acre North Twin impoundment.

5. Landlocked salmon were historically stocked periodically in the North Twin impoundment by MDIFW for 17 of the 36 years between 1937 and 1973, then annually from 1976 to 2010, and 2014-2017. A continuously decreasing number of salmon were stocked during the 2014-2017 timeframe. Stocking of landlocked salmon ended in 2017 after MDIFW gill net surveys at the time indicated a large percentage of captured salmon were of naturally reared origin. Presently, landlocked salmon in the North Twin impoundment consist of a self-sustaining naturally reproducing population relying on adequate and accessible spawning habitats. The Department is continuously striving to improve the salmon fishery to a healthy balance, and with that maintain an equally healthy population of rainbow smelt, the primary prey species of landlocked salmon. As outlined in the PAD, under the current operating license issued in 1996, Article 408 required the Licensee to maintain the North Twin impoundment at a minimum target level of 488.42 feet for the period August 22 through October 15 to accommodate lake trout spawning and incubation in October. However, after periodic lake trout monitoring during the early 2000's, it was determined wild lake trout reproduction was not occurring in the impoundment. Therefore, Article 408 was amended in 2012 to remove the minimum target lake elevation level during the period August 22 through October 15. With the minimum target lake elevation now removed, MDIFW believes that the Project's seasonal drawdown cycles could have a negative impact on landlocked salmon spawning and incubation within the impoundment and its tributaries. This study will also assist MDIFW on how best to manage the fishery and determine if significant lake level drawdowns are impacting salmon life movement, foraging, or spawning within the shoreline or movement up tributaries within the Project.

6. Radiotelemetry studies are routinely requested and utilized during the hydro relicensing process in Maine and elsewhere. Similar radiotelemetry studies have been proven essential to developing management plans for the Rapid River and West Branch fisheries, and similar studies at Moosehead Lake above the East Outlet Dam (FERC No. P-2671), Brassua Lake above the Brassua Dam (FERC No. P-2615), and in the Kennebec River downstream of Indian Pond Project (FERC No. P-2142) have been completed in recent years. The proposed study may be similar to other projects occurring at other hydroelectric projects but should include a sample size large enough to fully assess all movements including regular tracking events. Radiotelemetry is a highly effective means of determining salmonid movement and habits and determining potential Project-related impacts to their populations.

7. This study is commensurate with the scale of the Project, presumed new 40-year operating license, and the importance of the resource. The level of effort and cost, to include multi-season

sampling, is consistent with an impoundment of this magnitude. MDIFW needs a better understanding of the movement and spawning of naturally reared landlocked salmon fisheries in the North Twin impoundment and how the Project may or may not be impacting these fisheries to achieve MDIFW management goals.

**Study Request 9: Minimum Flow Analysis of Back Channel**

1. The goal of this study is to inform the decision process for determining the best timing and extent of minimum flow releases required to maximize fishery resources in terms of both aquatic habitat and fishable opportunities in the Back Channel (mainstem West Branch of the Penobscot River). The objectives of this study are to:

- Generate a comparative analysis of the various scenarios for minimum flow levels that best addresses and/or maximizes the needs of inland fisheries resources of the Back Channel.
- Evaluate how various minimum flows influence the fishable aquatic habitat in the various lotic and lentic reaches of the Back Channel.

2. The study is requested to ensure that any agreed upon minimum flow releases occur at levels that meet inland fisheries needs. The amounts of minimum flow releases are required to maximize aquatic freshwater fisheries habitat and fishable habitat, as well as maximize benefits to the aquatic macroinvertebrate community.

3. MDIFW is a cabinet level agency of the State of Maine.

4. Under the existing FERC license, minimum flows are not required in the Back Channel. The Back Channel is a 4.5-mile-long reach downstream of Stone Dam (Millinocket impoundment) that flows into Shad Pond. An Instream Flow Incremental Methodogy (IFIM) study was conducted using a transect-based Physical Habitat Simulation (PHABSIM) hydraulic model at 2 sites: one site located above Grand Falls, and another located below the Falls. However, at the time the only species that was evaluated in the Back Channel was Atlantic salmon.

Due to changing MDIFW fisheries goals and growing angler pressures in the region, MDIFW is trying to establish a seasonal put-and-take fishery in this resource to provide more angler opportunities. Given changing MDIFW management objectives for this resource since the original license was issued, MDIFW requests that minimum flows be re-evaluated at the Back Channel.

5. Minimum flow provisions are commonly required for hydropower operations in relation to how they impact the quality and quantity of aquatic habitat, fish passage, and/or recreational use of the site (e.g. wadability). An evaluation of minimum flow provisions is necessary to determine how best to meet the various resource needs including those of the Licensee, which may not be consistent among the various agencies and other interested parties. These data will inform conclusions regarding impacts to aquatic habitat to determine whether modifications to Project operations are needed. Data derived from this study will facilitate evaluation of the existing minimum flows, inform MDIFW's decision process, and contribute to the development

of an administrative record in support of protection and enhancement opportunities for freshwater fisheries and the aquatic community at large.

6. Minimum flow evaluations are commonly requested for hydropower project relicensing. This study request may parallel other agency flow study requests and should be a collaborative effort between MDIFW, other interested agencies, and the Licensee. Therefore, the study details, including the actual methodology, should be developed after a review of all study requests to minimize redundancy and meet the collective need for flow analyses. However, for the purpose of more clearly addressing expectations, MDIFW proposes one option of evaluation as calculating the Aquatic Base Flow (ABF, as calculated per current U.S. Fish and Wildlife Service methodology). MDIFW and interested resource agency staff, along with the Licensee, could then visually rate flow(s) with the intent of identifying a minimum flow that will enhance aquatic habitat and recreational opportunities below the dam. The actual test flows would be selected through a collaborative process involving MDIFW, other interested agencies, and the Licensee. Other types of methodologies might also be acceptable, including replicating the Instream Flow Incremental Methodology employing a Physical Habitat Simulation Model to quantify flow and habitat relationships, and the development of Weighted Usable Area outputs to characterize habitat suitability for landlocked salmon.

7. The level of effort and cost is commensurate with a project the size of the Penobscot Mills Project and the likely license term. The field work will likely require at least one field season to complete. Several days of field work and subsequent analyses may be needed to assess pre-determined locations of the river under various minimum flows. Only an evaluation of various minimum flow scenarios, whether modeled or conducted ***in situ*** can effectively determine the best approach for addressing flow releases for the Project.

**Study Request 10: Macroinvertebrates Study Request—Ripogenus Project**

1. The goal of this request is to determine if any changes have occurred in the macroinvertebrate species composition and/or abundance at the Ripogenus Project since the original study.

2. MDIFW is the natural resource agency responsible for managing fish and wildlife resources along the West Branch of the Penobscot River, with "wildlife" defined as all animals including insects and other macroinvertebrates. Macroinvertebrates are important forage for all fish species in the Project area.

3. MDIFW is a cabinet-level agency of the State of Maine.

4. GLHA performed extensive studies of macroinvertebrates in the Ripogenus impoundment and the West Branch of the Penobscot River below McKay Station for the current license. This information can be found in Volume VIII of the 1991 application.

5. There is concern that there are more frequent and more severe drawdowns on Ripogenus impoundment than anticipated, and they are occurring during the typical growing season. The extensive dewatered areas could be impacting macroinvertebrate populations and therefore negatively impacting fish growth and survival. In addition, there is concern that the West Branch of the Penobscot River below McKay Station is managed as more of a peaking operation

with flows exceeding 3,000 cfs during the day and 1,800 cfs or less in the evenings. Flow changes of this magnitude in a short period of time can dewater areas of the river and result in a loss of macroinvertebrate diversity and habitat, as well as cause direct mortality.

MDIFW believes the summer drawdowns and peaking operations were not fully anticipated in the review of the current license and therefore the water management plan may need to be refined. This study, along with the requested lake elevation and flow data, will provide information about the degree, frequency, and possible impacts resulting from the drawdowns and changes in flow.

6. Assuming there have been no changes to sampling methodology, MDIFW recommends using the exact same protocols from the 1991 application which were accepted by FERC and the agencies. We recommend the sampling take place in the same locations in the Ripogenus impoundment and the section of river between McKay Station and Ambajejus Lake. We request the Licensee report the results along with a comparison to the data presented in the 1991 application.

7. The level of effort and cost is commensurate with a Project the size of the Ripogenus Project and the likely license term. There are no proposed alternative studies, although MDIFW envisions that this request can be incorporated into other study requests.

Finally, MDIFW supports study requests prepared by other natural resource agencies, including but not limited to the Maine Department of Environmental Protection, the Maine Department of Marine Resources, the Maine Department of Agriculture, Conservation, & Forestry, and the US Fish and Wildlife Service.

Please feel free to contact my office if you have any questions regarding this information, or if I can be of any further assistance.

Best regards,

John Perry

**RE: Pre-Application Document Comments, Study Requests, and Scoping Document Comments for the Ripogenus (FERC No. 2572-133) and Penobscot Mills (FERC No. 2458-247) Hydroelectric Projects**

Dear Secretary Bose:

The Maine Department of Marine Resources (MDMR) is writing in response to the Federal Energy Regulatory Commission's (Commission) Notice of Intent to File License Application, Filing of Pre-Application Document (PAD), Commencement of Pre-Filing Process, Scoping, Requests and Comments on the Pad and Scoping Document, and identification of issues and Associated Study Request, dated June 11, 2021, for the Ripogenus and Penobscot Mills Hydroelectric Projects (collectively referred to as Projects), located on the West Branch of the Penobscot River and Millinocket Stream in Piscataquis and Penobscot Counties, Maine. The projects are operated by Great Lakes Hydro America, LLC (GLHA).

## A) Project Background

### Riponenus Project

The Ripogenus project is located on the West Branch of the Penobscot River and the Project includes an 83-foot-high and 795-foot-long dam consisting of two concrete ogee spillway sections totaling approximately 480 feet in length, a 37-foot-wide intake structure, a 178-foot-long gate section, and a 100-foot-long earth section. The project facilities create a 29,270-acre impoundment that extends approximately 20.8 miles upstream with a normal full pond elevation of 941.59 feet United States Geological Survey (UGSS) datum. The impoundment created by the project facilities totals 688,705 acre-feet of usable storage with a maximum drawdown of 44 feet and encompasses the following lakes and ponds: Ripogenus, Caribou, and Chesuncook Lakes; Black, Brandy, and Moose Ponds.

The Ripogenus project also includes a 16-foot-diameter and approximately 3,850-foot-long tunnel, penstocks, a powerhouse (McKay Station) with three vertical Francis turbines with a total authorized capacity of 37,530 kW, and 50-foot-long excavated bedrock tailrace. Water that is diverted through the tunnel bypasses the river reach of the West Branch known as the “Upper Gorge” and instead flows

OFFICES AT 32 BLOSSOM LANE, MARQUARDT BUILDING, AUGUSTA, MAINE
http://www.Maine.gov/dmr
PHONE: (207) 624-6550 FAX: (207) 624-6024

through the 2-5/8 inch clear spaced trashracks of the intake structure at the Ripogenus Dam, to McKay Station via the tunnel, through the turbines, and is discharged via the excavated tailrace. The tailrace enters the main river channel at an approximately 90-degree angle. The hydraulic capacity of McKay Station is 3,500 cfs.

The Ripogenus project contains one utility-scale battery energy storage site.

**Penobscot Mills Project**

The Penobscot Mills project consists of four hydropower developments (North Twin, Millinocket, Dolby, and East Millinocket) located on the West Branch and one storage development (Millinocket Lake) located on Millinocket Stream. The total authorized installed capacity of the Penobscot Mills Project is 67.9 MW

*Millinocket Lake Storage Development*
The Millinocket Lake Storage Development consists of a 635-foot-long and approximately 18.8-foot-high concrete and earth-filled dam located at the outlet of Millinocket Lake and a pumping station containing two pumps, two 4.5-foot-diameter steel pipes measuring approximately 544-feet-long, and a concrete outlet structure discharging into Ambajejus Lake (within the North Twin impoundment). The dam includes a 19-foot-long spillway section and an adjacent 58-foot-long gated section that contains four lift gates and one log sluice gate. The normal full pond elevation of the lake is 480 feet with a surface area of approximately 8,640 acres. According to GLHA, usable storage is 45,370 acre-feet with a 6.2-foot drawdown.

*North Twin Development*
The North Twin Development consists of a 1,051-foot-long and approximately 35-foot-high concrete and earth-filled structure at the outlet of Elbow Lake. The dam includes a 114-foot-wide intake structure and powerhouse, a 34-foot-wide fishway "for resident fish species", a 117-foot-long tainter gate section, and a 286-foot-long earthen embankment. In addition to the dam, there are a series of six earthen dikes having a combined length of 2,530 feet, located upstream of the dam, which retain water. The North Twin impoundment has a normal full pond elevation of 491.92 feet with a surface area of 17,790 acres and includes: Elbow, South Twin, North Twin, Pemadumcook, and Ambajejus Lakes. According to GLHA, the impoundment's usable storage is about 344,355 acre-feet with a drawdown of 22 feet. Of note, the Millinocket Lake Development includes a pumping station that conveys water from Millinocket Lake and is discharged to Ambajejus Lake, which is included the impoundment for the North Twin Development.

The intake structure to the North Twin powerhouse includes nine water passages, each 8 feet wide by 13 feet high and equipped with a steel gate to control the flow of water to the turbines. Trashracks constructed of 3/8-inch bar still with 2-5/8-inch clear bar spacing are located on the upstream side of the intake structure of the powerhouse. The North Twin powerhouse includes two fixed-blade vertical turbines in addition to a Kaplan turbine with an adjustable blade runner with a total rated capacity of 7,012.5 kW and a total hydraulic capacity is 4,500 cfs. The powerhouse also includes six tailrace bays with a combined width of 104 feet that conveys water back into the West Branch.

*Millinocket Development*
The Millinocket Development consists of a 1,262-foot-long concrete gravity dam ("Stone dam") located at the outlet of Quakish Lake. The dam directs water away from the West Branch and into the western

OFFICES AT 32 BLOSSOM LANE, MARQUARDT BUILDING, AUGUSTA, MAINE
http://www.Maine.gov/dmr
PHONE: (207) 624-6550 FAX: (207) 624-6024

canal which leads to Ferguson Pond and eventually Millinocket Stream. The concrete dam consists of a 300-foot-long overflow spillway section with no flashboards, a 358-foot-long spillway section with 30-inch-high flashboards a 52-foot-wide waste gate structure; a 428-feet, 5-inch-long spillway with a 2.75-foot-high rubber inflatable dam; and a 124-foot-long gatehouse. The gatehouse is used to regulate the flow into the western canal, which conveys water from Quakish Lake to Ferguson Pond. The western canal is approximately 150 feet wide and 1,400 feet long. The trashracks for the six 10-foot diameter penstocks have a clear spacing of 2-7/8 inches, while the trashracks for the single 11-foot diameter penstock have a clear spacing of 2-1/2 inches. There are eight horizontal Francis turbines at the project. According to GLHA, Unit 2 is "currently out-of-service and, therefore, is not included in the total rated capacity or hydraulic capacity of the station; however, GLHA routinely evaluates rehabilitation of the unit based on market conditions and other factors." Excluding Unit 2, the total rated capacity of the station is 37,374.8 kW and the total hydraulic capacity is 4,305 cfs. Water exits the turbines through seven, 25-foot-wide tailrace bays discharged directly into Millinocket Stream.

*Dolby Development*

The Dolby Development consists of a 1,395-foot-long and approximately 56-foot-high concrete and earthen dam that crosses the West Branch at the outlet of Dolby Pond. The project includes an approximately 4.2-mile-long impoundment with a normal full pond elevation of 336.2 feet with a surface area of 2,048 acres. The project dam includes a 27-foot-long concrete abutment, four spillway sections with a total length of 521 feet, two 6-foot-long abutments, a 76-foot-wide waste gate, a 209-foot-wide intake with an integral powerhouse, and 300-foot-long and 250-foot-long earthen dikes. The intake structure for the Dolby Development contains nine water passages that convey water to the four operable turbines. Eight sets of trashracks extend 174 feet across the upstream side of the intake structure. The trashracks for bays 2 through 4 are 3/8-inch bar steel with 1-5/8-inch clear bar spacing., while the trashracks for bays 5 through 8 are 3/8-inch bar steel 2-5/8-inch clear bar spacing. The powerhouse contains three inclined Kaplan turbines and one vertical, fixed-blade turbine (Units 5, 6, 7 and 8) with a total authorized installed capacity of 16,513 kW and a total hydraulic capacity of 4,750 cfs. According to GLHA, "the turbine-generators located in the No. 1, 2, 3, and 4 bays have been removed from service…however, GLHA routinely evaluates rehabilitation of these units based on market conditions and other factors." Water exits the four operable turbines through four tailrace bays (5, 6, 7, and 8) into a 189-foot-wide tailrace. According to GLHA, "Bays No. 1, 2, 3, and 4 are no longer used."

*East Millinocket Development*

The East Millinocket Development is located approximately 1.7 miles upstream of the Medway project (FERC No. 2666) on the West Branch. The Project consists of a 717.5-foot-long and approximately 31-foot-high concrete and earth dam with two spillway sections measuring 212 feet and 154 feet, a 59-foot-wide waste gate structure, 7-foot-wide timber crib section, 23-foot-wide sluice gate, and a 146-foot, 6-inch-wide intake structure integral with the powerhouse. The impoundment extends from the dam 1.9 miles upstream to the tailwater of the Dolby Dam. The surface area of the impoundment is 128 acres at normal pull pond elevation of 287.2 feet. The intake contains 12 gate openings that lead to 6 covered flumes in which the six horizontal Francis turbines are located. The trashracks are located immediately upstream of the gate openings and are 3/8-inch bar steel with 1-1/4-inch clear bar spacing. The total authorized capacity of the project is 6,975 kW and the total hydraulic capacity is 4,200 cfs.

*Protection, Mitigation, and Enhancement Measures*

There are no fish passage facilities associated with the Ripogenus Project. There is one fishway associated with the North Twin Development, but no other fish passage facilities associated with the other facilities for the Penobscot Mills Project. GLHA has not proposed additional protection,

mitigation, or enhancement (PME) measures at any of the facilities included in the licenses for the Ripogenus Project or the Penobscot Mills Project.

**COMMENTS on PAD**

*1.4 Post-ECPA Relicensings*

The PAD states,

> "The previous relicensing of the Projects was a massive undertaking that exhaustively studied and modified many aspects of the Projects' original licenses. Additionally, subsequent to the issuance of the licenses in 1996, significant additional monitoring occurred at both Projects to evaluate the success of the measures required by the licenses.
> As a result, the Projects operate under an array of highly beneficial and effective PM&E measures that enhance aquatic and terrestrial habitats throughout the Project areas, while serving as a critical component for the seasonal management of water flows throughout the Penobscot River Basin. These PM&E measures comprehensively address resource interests specific to the Project areas, as well as the larger river basin. These interests include water quality; management and balancing of flows within and downstream of the West Branch; aquatic and terrestrial resources; whitewater and recreational opportunities; cultural resources; and land management."

While the previous relicensing and subsequent additional monitoring resulted in PME measures at the Projects, these measures patently neglected to address impacts to diadromous fish with historic habitat within the project areas. The Project areas include historic habitat for Atlantic Salmon, American Shad, alewife, Blueback Herring, Sea lamprey, and American Eel. All of these species, except American eel, have been excluded from the Project area by the lack of fish passage at the Project facilities. MDMR looks forward to this relicensing addressing this oversight.

*4.3 Existing Project Facilities*

According to GLHA, "Water exits the four operable turbines through four tailrace bays into a 189-foot-wide tailrace. Bays No. 1, 2, 3, and 4 are no longer used." While GLHA is clear that the tailraces bays associated with the inoperable units are no longer used, it is not clear if the intake structures for those units are still in use. MDMR requests GLHA clarify which intake bays are in use at the Dolby Development. In addition, GLHA provided detail on the trash rack structures for Bays 2-8. MDMR requests GLHA provide detail on the trash rack structure for Bay 1 at the Dolby Development.

Shad Pond and the section of the West Branch of the Penobscot River upstream of Shad Pond to the Millinocket Development Dam are depicted in Figure 4.2 and were described in the during the Scoping meeting on September 9, 2021, as the "back channel". MDMR requests that the term "back channel" be removed from the PAD. This term causes confusion as it misrepresents this section of the river, which is the only channel of the West Branch of the Penobscot River. This channel is the West Branch of the

OFFICES AT 32 BLOSSOM LANE, MARQUARDT BUILDING, AUGUSTA, MAINE
http://www.Maine.gov/dmr
PHONE: (207) 624-6550 FAX: (207) 624-6024

Penobscot River. MDMR recommends the term "West Branch of the Penobscot River below the Stone Dam" be used in its place.

*4.4 Project Operations*

The PAD did not contain adequate information to describe fluctuation in surface elevations in the impoundments of the Projects. MDMR requests that the Licensee include a summary of data on the surface elevation of the impoundments for each of the Projects. This data should include average, minimum, and maximum elevations for each of the impoundments and when they occurred and should be reported yearly for the previous 20 years of operation under the current licenses.

In addition, MDMR requests similar information on the operations of the pumping station included in the facilities for the Millinocket Lake Storage Development. This data should include amount, duration of dailing pumping operations and should be reported for the previous 20 years of operation under the current licenses.

*5.3.2 River Flows*

The PAD provides a summary of flow data (monthly average outflow 2016-2020), however this summary is not adequate to assess flow through the Project area and the impact of Project operations on flow. In addition, no third-party flow data is available for the West Branch of the Penobscot River. The nearest USGS gauge station is located near the West Enfield Project (FERC No. 2600), which is more than 30 miles below the Projects and below the confluence of several tributaries on the mainstem of the Penobscot River. MDMR requests GLHA provide detailed daily data for flows, head pond elevations, and operations for each of the Project facilities reported for the previous 20 years of operation under the current licenses. Without the disclosure of data, the impacts of the current operation of the Projects are difficult to assess. In addition, without the disclosure of data on how the Projects have been operated in recent years, it is difficult to determine if the projects are operating under "store-and-release" or "peaking" modes. These changes in operations have impacts on water temperature and other water quality measures in the habitats within the Project area and downstream of the Projects and has the potential to negatively impact ESA listed Atlantic salmon and other aquatic species and habitats. Energy demands have changed dramatically since the Projects were licensed due to the closer of the Mills. These changes have led to changes in Project operations.

This request from MDMR is for data that is already available to the Applicant and thus is not included our study requests.

*5.4 Fish and Aquatic Resources*

The PAD states, "The Penobscot River basin supports a variety of diadromous fish species including Atlantic salmon, American shad, alewife, and blueback herring (collectively referred to as river herring),

American eel, and sea lamprey during some portion of their life histories. None of these species currently occur in waters of the Ripogenus or Penobscot Mills Projects, except for the catadromous American eel. The West Branch is not currently managed for anadromous fish."

The West Branch of the Penobscot River contains historic habitat for Atlantic Salmon, American shad, American Eel, Alewife, Blueback herring, and Sea Lamprey. American eel are also currently present in the Project impoundments. As stated in the 2008 Strategic Plan for the Restoration of Diadromous Fishes to the Penobscot River (2008 Plan), "…the 10 hydropower and water storage dams on the West Branch Penobscot do not pass diadromous fish and no passage is planned in the near term."[1] The lack of upstream and downstream passage measures at relevant Project facilities has prevented active restoration of diadromous species to the West Branch of the Penobscot River. In other words, the West Branch Penobscot is not currently managed for anadromous fish because of the lack of passage at the Project facilities. Significant progress on restoration goals laid out in the 2008 Plan have been met in the years since its writing. While the 2008 Plan did not target the West Branch for restoration at the time, that does not mean that restoration should not happen in the future.

*American Eel (Anguilla rostrata)*

As indicated in the PAD, "American eel have been found in each of the Project impoundments." In fact, American eel were documented as part of the fish assemblage catches from the previous relicensing of the Project[2]. However, in the intervening years there have been no upstream or downstream passage facilities or operational measures installed or implemented at any of the Project facilities. In addition, no studies have been completed to inform Project specific information related to impacts to American eels. To address these data needs, MDMR includes study requests in this filing that seek to address the following gaps in information.

- Where do juvenile eels concentrate below each dam?
- What is the timing and number of eels that approach each facility and at what size do they migrate through the relevant Project facilities?
- What is the mortality for each potential route of passage for downstream migrating adult eels?
- What are the downstream passage alternatives that best meet the standards of safe, timely, and effective?

http://www.Maine.gov/dmr
PHONE: (207) 624-6550 FAX: (207) 624-6024

*American Shad (Alosa sapidissima)*

American shad habitat in the West Branch of the Penobscot River was documented well before the development of the Project[345]. As stated in the PAD, "the segment of the West Branch between the Mattaceunk Project (FERC No. 2520) Dam and Grand Falls accounts for 1.7 percent of the Penobscot River basin's potential American shad production." This equates to production potential of approximately 25,773 adult shad annually based on the 9,372 units of habitat (1 production unit is 100 $m^2$).

Currently, there are no upstream or downstream passage and protection measures installed at the Project facilities for American Shad. MDMR includes in this filing study requests that seek to addresses gaps in information that will be needed to develop PME measures for American Shad.

*Atlantic Salmon (Salmo salar)*

Atlantic salmon historically occurred throughout the Penobscot River basin including in the West Branch of the Penobscot River as far as Penobscot Brook on the South Branch as well as in the North Branch[6]. Compared to other tributaries of the river, the West Branch includes a significant amount of high-quality Atlantic salmon habitat. In addition, critical habitat for Atlantic salmon extends to just below the Project areas, the confluence of the West Branch with the East Branch Penobscot River.

Currently, there are no upstream or downstream passage and protection measures installed at the Project facilities for Atlantic salmon. MDMR includes in this filing study requests that seek to addresses gaps in information that will be needed to develop PME measures for Atlantic salmon.

*Other Diadromous Species*

The PAD does not include any information on Alewife (*Alosa pseudoharengus*), Blueback herring (*Alosa aestivalis*), or Sea Lamprey (*Petromyzon marinus*) within the Project area. The upstream migratory extent for Alewife and Blueback herring is documented as similar to that of American Shad, indicating that Grand Falls was likely the first natural barrier to migration[78]. This indicates that Dolby Pond, Shad Pond, and Millinocket Lake were all historic habitat for Alewives and the associated riverine habitat for Blueback herring. Given the lack of natural barriers and the similarities in upstream

[8] Saunders, R. M. A. Hachey, C.W. Fay. 2006. Maine's Diadromous Fish Community: Past, Present, and Implications for Atlantic Salmon Recovery. Fisheries 31(11):537 - 547.

OFFICES AT 32 BLOSSOM LANE, MARQUARDT BUILDING, AUGUSTA, MAINE
http://www.Maine.gov/dmr
PHONE: (207) 624-6550 FAX: (207) 624-6024

migration behavior and spawning habitat between Sea Lamprey and Atlantic salmon, it is assumed that Sea Lamprey had a similar historic extent as salmon in the West Branch[9].

Currently, there are no upstream or downstream passage and protection measures installed at the Project facilities for Alewife, Blueback herring, or Sea Lamprey. MDMR includes in this filing study requests that seek to addresses gaps in information that will be needed to develop PME measures for Alewife, Blueback herring, or Sea Lamprey.

*5.7.5 Biological Opinions, Status Reports, and Recovery Plans for Listed Species*

The PAD states, "Several biological opinions, status reports, and recovery plans have been developed for Atlantic salmon; however, Atlantic salmon are not found within the Project waters, as they are concentrated in the mainstem Penobscot River, East Branch Penobscot River, and other tributaries downstream of the Projects." Salmon are not present within the project area because of the lack of fish passage at the projects, which has impacted this endangered species as well as other diadromous species. This impact is clearly articulated in the 2019 Atlantic Salmon Recovery Plan (USFWS and NOAA)[10].

> "Damming rivers, thus preventing migration to former spawning grounds, was a major factor in the decline of Atlantic salmon, sturgeon, river herring (blueback herring and alewife), and shad."

*5.7.6 Federally-Designated Critical Habitat for Listed Species*

While the West Branch of the Penobscot River was not included in critical habitat for GOM DPS of Atlantic salmon, the West Branch is well documented as historic habitat for the species. As climate change continues to impact habitat downstream of the Projects, habitat in the West Branch may be an important asset to recovering Atlantic salmon in the future.

*RECOMMENDED STUDIES*

GLHA is not proposing to undertake any studies as part of this relicense proceeding. Enclosed please find our formal study requests (Attachment A) in the format required pursuant to 18 CFR §4.38(b)(5). In addition, MDMR supports the study requests of Maine Department of Environmental Protection, Maine Department of Inland Fisheries and Wildlife, U.S. Fish and Wildlife Service (Accession No. 20211007-5023), and NOAA Fisheries (Accession No. 20211008-5254).

# Study Request #1
# Three-Dimensional Computational Fluid Dynamics (CFD) Modeling Upstream and Downstream of the Discharge and in the Vicinity of Powerhouse Forebays

***Goals and Objectives***

The goal of this study is to determine the flow field conditions that exist upstream of the project powerhouse under existing condition and potential future conditions. The information from this study can be coupled with data from our other requested studies of downstream passage to develop a comprehensive understanding of migratory fish behavior. The objective of this study is to develop a series of layered drawings that show velocity magnitudes at discharges that have been agreed upon by the resource agencies and the licensee. We request that the following three flow conditions be studied at the minimum: a) river flow at powerhouse capacity, no spill; b) river flow at 50% powerhouse hydraulic capacity, no spill; and c) river flow at 20% exceedance on the May through October flow duration curve with the powerhouse operating at capacity and excess flow being spilled either through gates or over the spillway. The CFD modeling should also be conducted for at least these three aforementioned conditions for each alternative studied in the Downstream Fish Passage Alternatives Study. We expect the results demonstrate velocities and flow orientations upstream of the powerhouse and along the racks.

The goal of this study is to determine the potential impacts of the East Millinocket Development, Dolby Development, Millinocket Development, North Twin Development, Millinocket Lake Storage Development, and the Ripogenus dams on: (1) the zone of passage for migratory fish near turbine discharge; and (2) natural flow regimes in the West Branch of the Penobscot River immediately upstream and downstream of each project.

Specific objectives of the study include:

1. Develop a CFD model of the full width of the West Branch upstream and downstream of each projects discharge.

2. Model flow characteristics upstream and downstream of the project under existing project operations and at several representative river flow levels, as well as any other modifications under consideration (including potential future impacts to operations as a result of climate change), to assess potential impacts to fish and wildlife resources.

3. Assess velocities and flow fields at, and in proximity to each project's intake/discharge structure when generating, and their potential to (1) interfere with fish migration; (2) create undesirable attraction flows; and (3) result in fish entrainment and/or impingement.

4. Assess the potential for velocity barriers to aquatic organism movement in the mainstem river resulting from generation flows at each project, alone and in combination with generation flows from the other projects on the West Branch.

5. Model, and then evaluate, flow characteristics under alternative project operations with potential measures to avoid, minimize, or mitigate impacts to fish and wildlife resources.

OFFICES AT 32 BLOSSOM LANE, MARQUARDT BUILDING, AUGUSTA, MAINE
http://www.Maine.gov/dmr
PHONE: (207) 624-6550 FAX: (207) 624-6024

6. Define flow velocities, fields/magnitudes, and direction in front of each project's powerhouse.

This information is necessary to properly assess the scale, and feasibility, of potential upstream and downstream passage alternatives (see the *Downstream Passage Alternatives* study request). The requested information can be utilized to create a more productive, cost-effective, and efficient alternatives analysis process by helping to narrow the focus to a minimal number of feasible alternatives.

***Resource Management Goals***
MDMR is a cabinet level agency of the State of Maine. MDMR was established to regulate, conserve, and develop marine, estuarine, and diadromous fish resources; to conduct and sponsor scientific research; to promote and develop marine coastal industries; to advise and cooperate with state, local, and federal officials concerning activities in coastal waters; and to implement, administer, and enforce the laws and regulations necessary for these purposes. MDMR is the lead state agency in the restoration and management of diadromous (anadromous and catadromous) species of fishes. In order to achieve the State of Maine's restoration goals for these species in the Penobscot River, the Projects must provide safe and effective passage.

***Public Interest***
The requestor is a state natural resource agency.

***Existing Information and the Need for Additional Information***
No project-specific information exists that will allow for a comprehensive assessment of existing project operations on West Branch flows and on fish and aquatic organisms in the project areas upstream and downstream of each dam. The Pre-Application Document does not contain any information, or tool(s), that will allow for predictions of impacts of alternative project operations, or potential mitigation measures to protect or enhance aquatic fish and wildlife resources. Further, a comprehensive understanding of fish behavior at each powerhouse forebay is needed to create safe, timely, and effective upstream and downstream passage for Atlantic Salmon, American shad, American Eel, Alewife, Blueback herring, and Sea Lamprey on the West Branch. CFD models are a relatively cost-effective way to analyze existing and future conditions. As such, changes in the amount of attraction water, changes in which turbines are operating, and which spillway gates are releasing water can all be examined.

MDMR notes, modeling this information now can help the resource agencies, as well as the Applicant, account for potential drought and/or flood related scenarios that might occur during the duration of any newly issued license, due to climate change and other factors.

***Nexus to Project Operations and Effects***
The Ripogenus Project has direct impacts to instream flows, aquatic habitats, and upstream and downstream migrating Atlantic salmon, American eel, and Sea Lamprey in the West Branch of the Penobscot River. The Penobscot Mills Project has direct impacts to instream flows, aquatic habitats, and upstream and downstream migrating Atlantic Salmon, American shad, American Eel, Alewife, Blueback herring, and Sea Lamprey in the West Branch of the Penobscot River. The development of the requested CFD models will aid in determining the potential impacts of the East Millinocket Development, Dolby Development, Millinocket Development, North Twin Development, Millinocket Lake Storage Development, and Ripogenus dam. For downstream passage, the U.S. Fish and Wildlife Service (FWS) has velocity vector guidelines associated with intake racks and guidance

OFFICES AT 32 BLOSSOM LANE, MARQUARDT BUILDING, AUGUSTA, MAINE
http://www.Maine.gov/dmr
PHONE: (207) 624-6550 FAX: (207) 624-6024

screens; the output from these models will inform the resource agencies under what conditions appropriate velocities are being met and when they are being exceeded. Additionally, modeling of flow will aide in our interpretation of year one downstream passage telemetry results. Therefore, aspects of the CFD modeling effort could focus on the locations identified as important in the study results and GLHA could assess changes to structures of operations and evaluate them in the model. Suitable alternatives would then be tested in year three studies.

***Methodology Consistent with Accepted Practice***

A three-dimensional CFD model has become an increasingly common standard of analysis at hydroelectric projects across the nation. Within the northeast region, we have seen these types of models developed at the Holyoke (P-2004), Brunswick (P-2284), Shawmut (P-2322), Milford (P-2534) and Lowell (P-2790) projects. We would expect to engage with the licensee in terms of determining the appropriate areas and flows to be modeled. We expect the spatial extent of the model at each study site will vary. Given the large number of ways in which output from these models can be presented and the near infinite number of flows which could potentially be modeled, we would expect to consult with the applicant to reach agreed upon modeling efforts and scenarios to be examined.

***Level of Effort/Cost, and Why Alternative Studies Will Not Suffice***

The cost of developing, running, and testing a CFD model can vary tremendously; one large variable in determining the cost is based on the amount of existing bathymetric data to which GLHA currently has access. We roughly estimate the maximum cost of each CFD model to be $50,000, assuming no bathymetric data currently exists. Proactive communication with resource agencies will reduce the cost and iterative effort. Given the level of effort that has occurred at other projects where licensees have proposed to amend their license, we see the level of effort requested here as reasonable, given that GLHA is seeking a renewal of its license.

Regarding alternatives, no project-specific instream flow analysis tool has been developed for the West Branch that will allow for assessment of existing operations and alternative operational impacts on instream flow and aquatic habitat for fish and wildlife resources. Further, the model, once built, can be used to simulate flow conditions in the vicinity of each project during the migratory fish passage season and can be used together with behavior studies (i.e., telemetry studies and entrainment studies requested herein) to assess the impacts of varying project operations or potential mitigation operations and measures on fish migration and aquatic habitat. MDMR knows of no other tool that will provide for these types of assessments. No alternatives are proposed.

## Study Request #2
## Upstream American Eel Passage Assessment

The PAD identifies American eel as present in the Project area. Dams, such as East Millinocket Development, Dolby Development, Millinocket Development, North Twin Development, Millinocket Lake Storage Development, and the Ripogenus dam, are known to impair migration success for catadromous species such as American eel (ASMFC 2014). Presently, upstream passage facilities specific to the needs of migrating juvenile eels are not available at either project (or any of the dams that comprise the two projects). Installing upstream eel passage at each facility will address direct project related impacts and facilitate restoration of American eel within the Penobscot River watershed. The study request below is intended to provide data necessary to develop reasonable and prudent conservation measures, specifically safe, timely and effective passage for American eel. If aspects of the project design or project operations changes with any new license, this study may need to be repeated.

***Goals and Objectives***

The goal of this study is to assess the locations for dedicated upstream passage for American eel. The study has two objectives:

1. Conduct systematic surveys of eel presence/abundance below the East Millinocket Development, Dolby Development, Millinocket Development, North Twin Development, Millinocket Lake Storage Development, and the Ripogenus dam to identify areas of concentration of eels staging in pools or attempting to ascend wetted structures that would potentially establish the most effective location to place upstream eel passage facilities.
2. Collect eels with temporary trap/pass devices at areas identified from surveys as potential location of eel concentrations to assess whether eels can be collected/passed in substantial numbers, and whether locations are viable sites for permanent eel trap/pass structures.

***Resource Management Goals***

MDMR is a cabinet level agency of the State of Maine. MDMR was established to regulate, conserve, and develop marine, estuarine, and diadromous fish resources; to conduct and sponsor scientific research; to promote and develop marine coastal industries; to advise and cooperate with state, local, and federal officials concerning activities in coastal waters; and to implement, administer, and enforce the laws and regulations necessary for these purposes. MDMR is the lead state agency in the restoration and management of diadromous (anadromous and catadromous) species of fishes.

The Atlantic States Marine Fisheries Commission (ASMFC) has developed three documents related to the management of American eel and hydropower facilities:

1. Interstate Fishery Management Plan for American Eel. April 2000. Atlantic States Marine Fisheries Commission.
2. Addendum II to the Fishery Management Plan for American Eel. Atlantic States Marine Fisheries Commission. Approved October 23, 2008. 8 pp.
3. Addendum III to the Fishery Management Plan for American Eel. Atlantic States Marine Fisheries Commission. Approved August 2014. 19 pp.

OFFICES AT 32 BLOSSOM LANE, MARQUARDT BUILDING, AUGUSTA, MAINE
http://www.Maine.gov/dmr
PHONE: (207) 624-6550 FAX: (207) 624-6024

Objectives of the management plan include: (1) protect and enhance American eel abundance in all watersheds where eel now occur; and (2) where practical, restore American eel to those waters where they had historical abundance, but may now be absent, by providing access to inland waters for glass eel, elvers, and yellow eel, and adequate escapement to the ocean for pre-spawning adult eel. Addendum II contains specific recommendations for improving upstream and downstream passage of American eel, including requesting that member states and jurisdictions seek special consideration for American eel in the Commission's relicensing process.

MDMR's management goal is to restore American eel to their historic habitat in the Penobscot River. The waters upstream of Projects represent significant habitat for American eel. The protection, enhancement, and restoration of this species relies on safe, timely, and effective upstream fish passage at the Projects.

***Public Interest***
The requester is a state natural resource agency.

***Existing Information and the Need for Additional Information***
The PAD does not provide information relative to areas eels concentrate below the East Millinocket Development, Dolby Development, Millinocket Development, North Twin Development, Millinocket Lake Storage Development, or Ripogenus dams or an assessment of the numbers and size of eels attempting to ascend each facility. Data from this study will provide information in support of the licensing process and in developing the administrative record for potential mitigation measures under Section 10(j) of the Federal Power Act.

***Nexus to Project Operations and Effects***
Dams impede the safe, timely, and effective passage of eels. The ability of eels to pass a dam depends on factors such as its height, hydraulics, presence of climbable surfaces (e.g., rough surface, wetted substrate), presence of predators, and risk of exposure to heat or drying while climbing a dam among others (Solomon and Beach 2004). Passage is also limited by the size of eel present. Only small juvenile eels are able to scale vertical surfaces (Machut et al. 2007). The design of the East Millinocket Development, Dolby Development, Millinocket Development, North Twin Development, Millinocket Lake Storage Development, and the Ripogenus dam creates multiple potential sites for upstream migrating eels to congregate. Site-specific data are necessary to understand project effects and support the decision process for properly designing and siting eel passage facilities.

***Methodology Consistent with Accepted Practice***
This study request consists of two parts: (a) an initial survey for presence and identification of areas where juvenile eels congregate and (b) a site evaluation for permanent eel passage. The methodologies described here are consistent with commonly accepted practices.

1. Objective 1: Systematic Surveys
Surveys of eel presence and relative abundance should be conducted at regular intervals (as described below) throughout the eel upstream migratory season (approximately April 1 to November 30). Surveys should consist of visual inspection and trapping in likely areas where eels may concentrate. Areas of quiescent water and leakage points along the downstream face of the dams should be targeted. Methods should include visual surveys (on foot, from a boat, or snorkeling) and trapping using small mesh (< 1/8" clear opening) baited eel pots. Visual surveys should be performed once per

week, at night, preferentially during precipitation events. Trap sets should be performed once per week, with an overnight soak time. Recorded data should include location, observation of eels (presence, absence, relative numbers, relative sizes, behaviors, time/date of observation), and survey method.

2. Objective 2: Trap/Pass Collections
Areas identified from the systematic surveys as having significant number of eels present should be targeted as potential areas for permanent eel trap/passes and should be initially assessed using temporary/portable trap passes. Temporary trap/passes should be purpose-designed and built for each location and operated throughout the eel upstream migratory season in the year following the survey. Ramp-type traps with supplementary attraction flow are preferred temporary trap/pass designs (Solomon and Beach 2004). Traps should operate daily, with catches quantified every 2-3 days. Data recorded should include location, trapping interval, absolute numbers of eels trapped, relative eel sizes, and hydraulic and environmental conditions during the trapping period.
All collected eels from surveys should be released at their point of capture; those eels collected from trap/pass collections should be transported to and released above each respective dam.

***Level of Effort/Cost, and Why Alternative Studies Will Not Suffice***
The level of cost and effort for the survey component of the study would be low; a minimal number of personnel may be able to conduct the weekly surveys. The trap/pass component would require low to moderate cost and effort. We estimate the cost will be approximately $50,000 for the study. No alternatives are proposed.

# Study Request #3
# Downstream American Eel Passage Assessment

***Goals and Objectives***

The goal of this study is to determine the impact of the East Millinocket Development, Dolby Development, Millinocket Development, North Twin Development, Millinocket Lake Storage Development, and the Ripogenus hydroelectric projects on the outmigration of silver eels in the West Branch of the Penobscot River. Project operations can result in delay, mortality or injury during emigration. It is important to understand the passage routes at the project and the potential for delay, injury, and mortality to determine measures and recommendations to increase survival and improve fish passage at the projects.

The objectives of this study are:

1. Quantify the movement rates, including delays, and relative proportion of eels passing via various routes at the project (i.e., through the turbines, through the downstream bypass, via spill at the dams, etc.).
2. Quantify the relative proportion of eels passing each potential emigration route (spill, bypass pipes, powerhouse) at the project during various project operations.
3. Evaluate instantaneous and latent mortality and injury of eels passed via each potential route.

***Resource Management Goals***

MDMR is a cabinet level agency of the State of Maine. MDMR was established to regulate, conserve, and develop marine, estuarine, and diadromous fish resources; to conduct and sponsor scientific research; to promote and develop marine coastal industries; to advise and cooperate with state, local, and federal officials concerning activities in coastal waters; and to implement, administer, and enforce the laws and regulations necessary for these purposes. MDMR is the lead state agency in the restoration and management of diadromous (anadromous and catadromous) species of fishes.

The Atlantic States Marine Fisheries Commission (ASMFC) has developed three documents related to the management of American eel and hydropower facilities:

1. Interstate Fishery Management Plan for American Eel. April 2000. Atlantic States Marine Fisheries Commission.
2. Addendum II to the Fishery Management Plan for American Eel. Atlantic States Marine Fisheries Commission. Approved October 23, 2008. 8 pp.
3. Addendum III to the Fishery Management Plan for American Eel. Atlantic States Marine Fisheries Commission. Approved August 2014. 19 pp.

Objectives of the management plan include: (1) protect and enhance American eel abundance in all watersheds where eel now occur; and (2) where practical, restore American eel to those waters where they had historical abundance, but may now be absent, by providing access to inland waters for glass eel, elvers, and yellow eel, and adequate escapement to the ocean for pre-spawning adult eel. Addendum II contains specific recommendations for improving upstream and downstream passage of American eel, including requesting that member states and jurisdictions seek special consideration for American eel in the Commission's relicensing process.

MDMR's management goal is to restore American eel to their historic habitat in the Penobscot River. The waters upstream of Projects represent significant habitat for American eel. The protection,

enhancement, and restoration of this species relies on safe, timely, and effective downstream fish passage at the Projects.

***Public Interest***
The requester is a state natural resource agency.

***Existing Information and the Need for Additional Information***
The Pre-Application Document does not contain information on the route of passage or the amount of delay that occurs for emigrating adult eels. To date, no directed studies of eel entrainment or mortality have been conducted at the projects. These information gaps need to be filled so the natural resource agencies can assess the relative and cumulative impacts of project operations on outmigrating eels and develop adequate passage and protection measures to meet management goals and objectives.

***Nexus to Project Operations and Effects***
The East Millinocket Development, Dolby Development, Millinocket Development, North Twin Development, Millinocket Lake Storage Development, and the Ripogenus hydroelectric projects do not have entrainment prevention measures in place at their respective turbine intakes, nor are there designated spillway passage routes or fish bypass systems. To determine overall project survival, we need to understand the routes of emigration, the potential for delay under different river flow conditions and project operations, and the level of injury and/or mortality resulting from each potential passage route (i.e., the turbines, the spillway, etc). This study will contribute information in support of the licensing process, and development the administrative record in support of potential mitigation measures under Section 10(j) of the Federal Power Act.

***Methodology Consistent with Accepted Practice***
In order to understand the movements of outmigrating silver eels as they relate to operations at Ripogenus and Penobscot Mills, radio telemetry technology should be utilized. Radio- and PIT-tagging is an accepted technology which has been used for a number of studies associated with hydropower projects, including at projects in the mainstem Penobscot River and the Merrimack River.

Studies should be designed to investigate the size class among the full spectrum of silver eels at each project, route selection (i.e., entrainment vs. spill) independently from estimation of mortality/injury, because these metrics require different methodologies. Studies will also likely benefit from data collected over two study years to account for differences in environmental conditions and natural variation in eel migration (especially route selection studies, which may be more significantly affected by environmental conditions during a given season than mortality/injury studies). It is also envisioned that results from route selection studies can guide design of turbine mortality studies. Therefore, it is proposed, at a minimum, route selection studies be conducted in multiple years, but mortality/injury studies may be conducted after the first year of route selection studies have been completed.

**Objective 1: Route Selection**
This study will involve systematic releases of radio- and PIT-tagged silver phase eels at strategic points above areas of interest, to assess general routes of passage (i.e., via spill, bypass, or turbines). Active downstream migrants should be collected within-basin if possible, but fish sourced from out-of-basin may be acceptable to meet sample size demands. Experimental fish

must meet morphometric (e.g., eye diameter relative to body size) criteria to ensure they are migrant silver phase. Collections should be made within the migratory season, and eels should be tagged and released within 21 days after capture, but preferably within 7 days (particularly if the test eels are from out-of-basin).

All telemetered eels will be radio- and PIT-tagged. PIT antennas will be installed and monitored continuously to verify passage of eels via bypass channels.

A minimum number of 150 telemetered eels (e.g., five separate groups of approximately 30 eels each) per development will be required to maximize the data return. If enough eels cannot be captured for this study in a single year, the study will need to take place over the course of two years. Tagged eels should be released at an appropriate distance upstream of each dam. Groups of eels should be released during spill (if any) and non-spill and during periods of low, moderate, and high generation conditions. Since fish can drift a considerable distance downstream after they have died (Havn et al. 2017), a minimum of 25 dead eels should also be released as a control group in this study (at each project). Additionally, a control is needed to allow comparisons of movement rate and success of passed and non-passed eels in reaching the detection point downstream. Therefore, an additional 50 telemetered (uninjured) eels should be released below each project and tracked as they emigrate.

Telemetry receivers and antennas should be located upstream and downstream of the spillway, at turbine intakes, station tailraces, etc. These locations will permit assessment of passage via the following potential routes: spillway; station turbines; any existing upstream fishway attraction water intake, etc. The final placement of receivers and antennas should be developed in consultation with the Service and the other agencies.

Mobile tracking (i.e., via boat) in the river between release sites and tens of kilometers downstream will be performed at regular intervals during and after releases to confirm routes and fates of passed fish or lost fish.

Movement rates (time between release and detection at radio antenna locations, and between radio antenna locations) of eels passing the projects by various routes will also be quantified.

The route selection portion of this study should occur in both study years.

**Objective 2: Spill, Bypass, and Turbine Mortality/Injury Studies**
Spill, bypass, and turbine mortality will be assessed using a balloon-tag method.

For spill mortality sites (dam spillways and downstream bypasses), tagged eels will be injected or released into spill flow at points where water velocity exceeds 10 ft/sec to minimize the possibility of eels swimming upstream into the headpond or canal. Passed balloon-tagged eels will be recovered below areas of spill and held for 96 hours in isolated tanks for observation of injury and latent mortality; unrecovered balloon-tagged eels will be censored from the data. Passed eels should be x-rayed for any potential injuries per Muller et al. 2020.

For turbine mortality sites, tagged eels will be injected into intakes of all units associated with the projects, operating at a full range of settings where intake water velocity exceeds 10 ft/sec to minimize the possibility of eels swimming back upstream through the intakes. Passed balloon-

OFFICES AT 32 BLOSSOM LANE, MARQUARDT BUILDING, AUGUSTA, MAINE
http://www.Maine.gov/dmr
PHONE: (207) 624-6550 FAX: (207) 624-6024

tagged eels will be recovered in the tailrace(s) and held for 48 hours in isolated tanks for observation of injury and latent mortality; unrecovered balloon-tagged eels will be censored from the data.
If the balloon-tag mortality component of the study occurs in study year one, all possible route selection sites would need to be evaluated. If the balloon-tag mortality component of the study occurs in study year two, results from the route selection study could be used to inform which sites need to be evaluated for mortality. Eels recovered from balloon-tag studies should not be used for route selection studies.

Data analyses of route selection and mortality (instantaneous and latent) will follow standard methodology.

Project operation (flows, levels, gate openings, number of units operating and operation level) and environmental conditions (river flow, temperature, turbidity, air temperature, precipitation) will be monitored regularly (hourly measurements if possible) throughout the duration of the studies and assessed for potential relationships to passage route selection, migratory delay, and/or passage survival.

These methodologies are consistent with accepted practice.

***Level of Effort/Cost, and Why Alternative Studies Will Not Suffice***

The level of cost and effort for the downstream eel passage study will be moderate to high; silver eels would need to be collected, tagged, and released in several locations over the course of the migration season. Data would need to be retrieved periodically, then analyzed. A multi-site route selection study conducted by the USGS Conte Lab on the Shetucket River in Connecticut cost approximately $75,000 for the first year of study. Costs are estimated at $100,000 per year for the route selection study and $50,000 to $75,000 for the spill, bypass, canal, and turbine mortality/injury study. No alternatives are proposed.

## Study Request #4
## Downstream Passage Alternatives Study

***Goals and Objectives***

The first goal of this study is to determine conceptual options, and expected performances for, improved downstream passage that will reduce delay, increase passage efficiency, and increase survival for downstream migrating adult and juvenile Atlantic Salmon, juvenile Sea Lamprey, and adult eels as they attempt to pass the North Twin Development and Ripogenus dam. The second goal of this study is to determine conceptual options, and expected performances for, improved downstream passage that will reduce delay, increase passage efficiency, and increase survival for downstream migrating adult and juvenile Atlantic Salmon, juvenile Sea Lamprey, adult eels, adult and juvenile alewife, and adult and juvenile blueback herring as they attempt to pass the East Millinocket Development, Dolby Development, Millinocket Development, and Millinocket Lake Storage Development.

***Resource Management Goals***

MDMR is a cabinet level agency of the State of Maine. MDMR was established to regulate, conserve, and develop marine, estuarine, and diadromous fish resources; to conduct and sponsor scientific research; to promote and develop marine coastal industries; to advise and cooperate with state, local, and federal officials concerning activities in coastal waters; and to implement, administer, and enforce the laws and regulations necessary for these purposes. MDMR is the lead state agency in the restoration and management of diadromous (anadromous and catadromous) species of fishes.

The Atlantic States Marine Fisheries Commission (ASMFC) has developed three documents related to the management of American eel and hydropower facilities:

1. Interstate Fishery Management Plan for American Eel. April 2000. Atlantic States Marine Fisheries Commission.
2. Addendum II to the Fishery Management Plan for American Eel. Atlantic States Marine Fisheries Commission. Approved October 23, 2008. 8 pp.
3. Addendum III to the Fishery Management Plan for American Eel. Atlantic States Marine Fisheries Commission. Approved August 2014. 19 pp.

Objectives of the management plan include: (1) protect and enhance American eel abundance in all watersheds where eel now occur; and (2) where practical, restore American eel to those waters where they had historical abundance, but may now be absent, by providing access to inland waters for glass eel, elvers, and yellow eel, and adequate escapement to the ocean for pre-spawning adult eel. Addendum II contains specific recommendations for improving upstream and downstream passage of American eel, including requesting that member states and jurisdictions seek special consideration for American eel in the Commission's relicensing process.

The Atlantic States Marine Fisheries Commission (ASMFC) has also developed four documents related to the management of Shad and River Herring (Alewife and Blueback Herring) and hydropower facilities:

1. Interstate Fishery Management Plan for American Shad and River Herrings. October 1985. Atlantic States Marine Fisheries Commission.

OFFICES AT 32 BLOSSOM LANE, MARQUARDT BUILDING, AUGUSTA, MAINE
http://www.Maine.gov/dmr
PHONE: (207) 624-6550 FAX: (207) 624-6024

2. Amendment 1 to the Interstate Fishery Management Plan for American Shad and River Herring. April 1999. Atlantic States Marine Fisheries Commission.
3. Amendment 2 to the Interstate Fishery Management Plan for American Shad and River Herring. May 2009. Atlantic States Marine Fisheries Commission.
4. Amendment 1 to the Interstate Fishery Management Plan for American Shad and River Herring. February 2010. Atlantic States Marine Fisheries Commission.

The objectives of the management plan include:

1. Prevent overfishing of American shad stocks by constraining fishing mortality below F30.
2. Develop definitions of stock restoration, determine appropriate target mortality rates and specify rebuilding schedules for American shad populations within the management unit.
3. Maintain existing or more conservative regulations for hickory shad and river herring fisheries until new stock assessments suggest changes are necessary. This should keep fishing mortality sufficiently low to ensure survival and enhancement of depressed stocks and the maintenance of stabilized stocks.
4. Promote improvements in degraded or historic alosine habitat throughout the species= range. State and federal managers should consider the following methods to achieve this objective:
    a. Improve or install passage facilities at dams and other obstacles to provide upstream passage to historic spawning areas, or remove these obstacles entirely.
    b. Improve water quality in areas where water quality degradation may have affected alosine stocks. C. Evaluate current fish passage facilities for efficiency.
    c. Ensure that decisions on river flow allocation (e.g., irrigation, evaporative loss, out of basin water transport, hydroelectric operations) take into account flow needs for alosine migration, spawning, and nursery usage.
    d. Ensure that water withdrawal (e.g., cooling flow, drinking water) effects (e.g., impingement and entrainment mortalities, turbine mortalities) do not affect alosine stocks to the extent that they result in stock declines.
    e. Evaluate and improve downstream passage for adults and juveniles.
    f. Promote and coordinate alosine stocking programs for:
        i. reintroduction to historic spawning area
        ii. expansion of existing stock restoration programs
        iii. initiation of new strategies to enhance depressed stocks.
    g. Promote cooperative interstate research monitoring and law enforcement.

MDMR's management goal is to restore Atlantic Salmon, American shad, American Eel, Alewife, Blueback herring, and Sea Lamprey to their historic habitat in the Penobscot River. The waters upstream of Projects represent significant habitat for American eel. The protection, enhancement, and restoration of this species relies on safe, timely, and effective downstream fish passage at the Projects.

***Public Interest***

The requester is a state natural resource agency.

***Existing Information and the Need for Additional Information***

As indicated in the Pre-Application Document (PAD), eels occur upstream and downstream of the Ripogenus and Penobscot Mills projects. The American eel is a native migratory fish species of the Penobscot River watershed with a catadromous life cycle. Eels are widely recognized as a species of high ecological value and significance in its native habitats and has a significant commercial value in

certain markets. In addition, eels were important historically to the Penobscot Indian Nation and other tribes for spiritual sustenance as well as physical subsistence.

In addition, MDMR included comments that speak to the importance of historic habitat for Atlantic Salmon, American shad, Alewife, Blueback herring, and Sea Lamprey in the West Branch of the Penobscot River.

In the PAD GLHA states that downstream passage is not provided at the East Millinocket Development, Dolby Development, Millinocket Development, North Twin Development, Millinocket Lake Storage Development, or Ripogenus dam. Therefore, the current configuration at each facility is not designed to today's fish passage design criteria and is likely insufficient to adequately pass the relevant diadromous species as they attempt to migrate downstream past each project. An alternatives analysis of the existing configuration at each dam and the subsequent impact(s) on adult and juvenile Atlantic Salmon, juvenile Sea Lamprey, and adult eels is needed to evaluate each existing project as well as potential future project design and operation(s). An alternatives analysis of the existing configuration for the East Millinocket Development, Dolby Development, Millinocket Development, and Millinocket Lake Storage Development also needs to take into account adult and juvenile alewife, and adult and juvenile blueback herring.

***Nexus to Project Operations and Effects***

Hydropower project related mortality and delay has a direct effect on migratory fish populations. East Millinocket Development, Dolby Development, Millinocket Development, North Twin Development, Millinocket Lake Storage Development, and Ripogenus dam all lack guidance structures to keep fish out of project turbines. Therefore, eels in the West Branch are likely not realizing their full juvenile production and adult escapement potential. While upstream passage has precluded restoration of Atlantic Salmon, American shad, Alewife, Blueback herring, and Sea Lamprey, once upstream passage is established, effective downstream passage will be critical to the restoration of these species. Data derived from this study will facilitate evaluation of various fish passage alternatives, inform the Commission's licensing process, and contribute to the development of an administrative record in support of protection and enhancement opportunities related to Atlantic Salmon, American shad, American Eel, Alewife, Blueback herring, and Sea Lamprey.

***Methodology Consistent with Accepted Practice***

Fish Passage Engineering Alternative studies are a common way to explore various options in the decision-making process and have been used by the Commission in several licensing proceedings. This study will require a review of existing downstream fish passage technologies that meet FWS fish passage criteria (USFWS 2019 or the most recent version, as they become available) and should consist of conceptual engineering designs of downstream fish passage options that include physical screening of fish, adequate flows for attraction, and adequate relative velocities directing fish to downstream passage structures. Expected performance of each alternative should also be included in any report developed for this study.

The alternatives GLHA proposes to study for each project, the depth and breadth of the conceptual design, and the itemization and source of costs (as well as any potential lost generation modeling) should be agreed upon by the resource agencies prior to GLHA conducting the study.

***Level of Effort/Cost, and Why Alternative Studies Will Not Suffice***

The level of cost and effort for this study would be low to moderate; we estimate the cost will be approximately $30,000. No alternatives are proposed.

# Study Request #5
# Upstream Passage Alternatives Study

***Goals and Objectives***

The first goal of this study is to determine conceptual options, and expected performances for, passage structures that will provide safe, timely, and effective upstream passage for upstream migrating adult Atlantic salmon and adult Sea Lamprey as they pass the North Twin Development and Ripogenus dam. The second goal of this study is determine conceptual options, and expected performances for, passage structures that will provide safe, timely, and effective upstream passage for upstream migrating adult Atlantic salmon, adult Sea Lamprey, adult alewife, and adult blueback herring as they attempt to pass the East Millinocket Development, Dolby Development, Millinocket Development, and Millinocket Lake Storage Development.

***Resource Management Goals***

MDMR is a cabinet level agency of the State of Maine. MDMR was established to regulate, conserve, and develop marine, estuarine, and diadromous fish resources; to conduct and sponsor scientific research; to promote and develop marine coastal industries; to advise and cooperate with state, local, and federal officials concerning activities in coastal waters; and to implement, administer, and enforce the laws and regulations necessary for these purposes. MDMR is the lead state agency in the restoration and management of diadromous (anadromous and catadromous) species of fishes.

The Atlantic States Marine Fisheries Commission (ASMFC) has developed three documents related to the management of American eel and hydropower facilities:

1. Interstate Fishery Management Plan for American Eel. April 2000. Atlantic States Marine Fisheries Commission.
2. Addendum II to the Fishery Management Plan for American Eel. Atlantic States Marine Fisheries Commission. Approved October 23, 2008. 8 pp.
3. Addendum III to the Fishery Management Plan for American Eel. Atlantic States Marine Fisheries Commission. Approved August 2014. 19 pp.

Objectives of the management plan include: (1) protect and enhance American eel abundance in all watersheds where eel now occur; and (2) where practical, restore American eel to those waters where they had historical abundance, but may now be absent, by providing access to inland waters for glass eel, elvers, and yellow eel, and adequate escapement to the ocean for pre-spawning adult eel. Addendum II contains specific recommendations for improving upstream and downstream passage of American eel, including requesting that member states and jurisdictions seek special consideration for American eel in the Commission's relicensing process.

The Atlantic States Marine Fisheries Commission (ASMFC) has also developed four documents related to the management of Shad and River Herring (Alewife and Blueback Herring) and hydropower facilities:

1. Interstate Fishery Management Plan for American Shad and River Herrings. October 1985. Atlantic States Marine Fisheries Commission.
2. Amendment 1 to the Interstate Fishery Management Plan for American Shad and River Herring. April 1999. Atlantic States Marine Fisheries Commission.

OFFICES AT 32 BLOSSOM LANE, MARQUARDT BUILDING, AUGUSTA, MAINE
http://www.Maine.gov/dmr
PHONE: (207) 624-6550 FAX: (207) 624-6024

3. Amendment 2 to the Interstate Fishery Management Plan for American Shad and River Herring. May 2009. Atlantic States Marine Fisheries Commission.
4. Amendment 1 to the Interstate Fishery Management Plan for American Shad and River Herring. February 2010. Atlantic States Marine Fisheries Commission.

The objectives of the management plan include:

1. Prevent overfishing of American shad stocks by constraining fishing mortality below F30.
2. Develop definitions of stock restoration, determine appropriate target mortality rates and specify rebuilding schedules for American shad populations within the management unit.
3. Maintain existing or more conservative regulations for hickory shad and river herring fisheries until new stock assessments suggest changes are necessary. This should keep fishing mortality sufficiently low to ensure survival and enhancement of depressed stocks and the maintenance of stabilized stocks.
4. Promote improvements in degraded or historic alosine habitat throughout the species= range. State and federal managers should consider the following methods to achieve this objective:
    a. Improve or install passage facilities at dams and other obstacles to provide upstream passage to historic spawning areas, or remove these obstacles entirely.
    b. Improve water quality in areas where water quality degradation may have affected alosine stocks. C. Evaluate current fish passage facilities for efficiency.
    c. Ensure that decisions on river flow allocation (e.g., irrigation, evaporative loss, out of basin water transport, hydroelectric operations) take into account flow needs for alosine migration, spawning, and nursery usage.
    d. Ensure that water withdrawal (e.g., cooling flow, drinking water) effects (e.g., impingement and entrainment mortalities, turbine mortalities) do not affect alosine stocks to the extent that they result in stock declines.
    e. Evaluate and improve downstream passage for adults and juveniles.
    f. Promote and coordinate alosine stocking programs for:
        i. reintroduction to historic spawning area
        ii. expansion of existing stock restoration programs
        iii. initiation of new strategies to enhance depressed stocks.
    g. Promote cooperative interstate research monitoring and law enforcement.

MDMR's management goal is to restore Atlantic Salmon, American shad, American Eel, Alewife, Blueback herring, and Sea Lamprey to their historic habitat in the Penobscot River. The waters upstream of Projects represent significant habitat for American eel. The protection, enhancement, and restoration of this species relies on safe, timely, and effective downstream fish passage at the Projects.

***Public Interest***

The requester is a state natural resource agency.

***Existing Information and the Need for Additional Information***

MDMR's comments in this filing speak to the importance of historic habitat for Atlantic Salmon, American shad, Alewife, Blueback herring, and Sea Lamprey in the West Branch of the Penobscot River.

In the PAD GLHA states that upstream passage is not provided at the East Millinocket Development, Dolby Development, Millinocket Development, Millinocket Lake Storage Development, or

Ripogenus dam. Therefore, the current configuration at each of these five facilities is not designed to today's fish passage design criteria and is likely insufficient to adequately pass the relevant diadromous species as they attempt to migrate downstream past each project. While the North Twin Development does have a fishway "for resident fish species", there is no known information on the effectiveness of the fishway. An alternatives analysis of the existing configuration at each dam and the subsequent impact(s) on adult Atlantic Salmon, and adult Sea Lamprey is needed to evaluate each existing project as well as potential future project design and operation(s). An alternatives analysis of the existing configuration for the East Millinocket Development, Dolby Development, Millinocket Development, and Millinocket Lake Storage Development also needs to take into account adult alewife, and adult blueback herring.

***Nexus to Project Operations and Effects***

Hydropower project related mortality and delay has a direct effect on migratory fish populations. East Millinocket Development, Dolby Development, Millinocket Development, Millinocket Lake Storage Development, and Ripogenus dam all lack upstream fish passage structures to allow fish access to upstream habitat. Lack of upstream passage extirpated Atlantic Salmon, American shad, Alewife, Blueback herring, and Sea Lamprey from historic habitat in the West Branch of the Penobscot River. Safe, timely, and effective upstream passage will be critical to the restoration of these species in the West Branch. Data derived from this study will facilitate evaluation of various fish passage alternatives, inform the Commission's licensing process, and contribute to the development of an administrative record in support of protection and enhancement opportunities related to Atlantic Salmon, American shad, Alewife, Blueback herring, and Sea Lamprey.

***Methodology Consistent with Accepted Practice***

Fish Passage Engineering Alternative studies are a common way to explore various options in the decision-making process and have been used by the Commission in several licensing proceedings. This study will require a review of existing downstream fish passage technologies that meet FWS fish passage criteria (USFWS 2019 or the most recent version, as they become available) and should consist of conceptual engineering designs of downstream fish passage options that include physical screening of fish, adequate flows for attraction, and adequate relative velocities directing fish to downstream passage structures. Expected performance of each alternative should also be included in any report developed for this study.

The alternatives GLHA proposes to study for each project, the depth and breadth of the conceptual design, and the itemization and source of costs (as well as any potential lost generation modeling) should be agreed upon by the resource agencies prior to GLHA conducting the study.

***Level of Effort/Cost, and Why Alternative Studies Will Not Suffice***

The level of cost and effort for this study would be moderate; we estimate the cost will be approximately $50,000. No alternatives are proposed.

# Study Request #6
# Evaluation of the Size of American Eels and the Timing of their Downstream Migratory Movements

***Goals and Objectives***

The goal of this study is to understand the size range of eels moving past the projects as well as the migration timing of adult, silver-phase American eels in relationship to environmental factors and operations of hydropower projects on West Branch of the Penobscot River.

The objective of this study is to quantify and characterize (1) the full spectrum of silver eel sizes at each project; and (2) the general migratory timing and presence of adult, silver-phase American eels in the West Branch relative to environmental factors and operations of the East Millinocket Development, Dolby Development, Millinocket Development, North Twin Development, Millinocket Lake Storage Development, and Ripogenus hydroelectric projects.

***Resource Management Goals***

MDMR is a cabinet level agency of the State of Maine. MDMR was established to regulate, conserve, and develop marine, estuarine, and diadromous fish resources; to conduct and sponsor scientific research; to promote and develop marine coastal industries; to advise and cooperate with state, local, and federal officials concerning activities in coastal waters; and to implement, administer, and enforce the laws and regulations necessary for these purposes. MDMR is the lead state agency in the restoration and management of diadromous (anadromous and catadromous) species of fishes.

The Atlantic States Marine Fisheries Commission (ASMFC) has developed three documents related to the management of American eel and hydropower facilities:

1. Interstate Fishery Management Plan for American Eel. April 2000. Atlantic States Marine Fisheries Commission.
2. Addendum II to the Fishery Management Plan for American Eel. Atlantic States Marine Fisheries Commission. Approved October 23, 2008. 8 pp.
3. Addendum III to the Fishery Management Plan for American Eel. Atlantic States Marine Fisheries Commission. Approved August 2014. 19 pp.

Objectives of the management plan include: (1) protect and enhance American eel abundance in all watersheds where eel now occur; and (2) where practical, restore American eel to those waters where they had historical abundance, but may now be absent, by providing access to inland waters for glass eel, elvers, and yellow eel, and adequate escapement to the ocean for pre-spawning adult eel. Addendum II contains specific recommendations for improving upstream and downstream passage of American eel, including requesting that member states and jurisdictions seek special consideration for American eel in the Commission's relicensing process.

MDMR's management goal is to restore Atlantic Salmon, American shad, American Eel, Alewife, Blueback herring, and Sea Lamprey to their historic habitat in the Penobscot River. The waters upstream of Projects represent significant habitat for American eel. The protection, enhancement, and restoration of this species relies on safe, timely, and effective downstream fish passage at the Projects.

http://www.Maine.gov/dmr
PHONE: (207) 624-6550 FAX: (207) 624-6024

***Public Interest***
The requester is a state natural resource agency.

***Existing Information and the Need for Additional Information***
The Pre-Application Document does not contain any information about (1) the size range of American eels in the West Branch of the Penobscot River; or (2) timing of downstream migratory movements and rates of eels in the West Branch. This information gap needs to be filled, as it relates directly to (1) more fully understanding survival estimates which will be provided via the requested *Downstream American Eel Passage Assessment*; and (2) when downstream passage and protection measures need to be operated.

***Nexus to Project Operations and Effects***
The timing of downstream migration of adult eels is not defined for the West Branch of the Penobscot River and there is no information about the size of the eels attempting to move downstream past the six projects that comprise Ripogenus and Penobscot Mills. Therefore, the general effects of hydroelectric project operations on eel survival to the ocean are unknown. Although separate study requests have been submitted to address project-specific downstream passage route selection, delays, and mortality of eels, general characteristics (size) of eels moving downstream and of river flow and environmental conditions may have significant relationships with project operation and eel migratory success and survival. For example, eels may tend to move immediately before or during periods of significant precipitation (or consequently river flow), times at which projects may be generating at maximum capacity or spilling, which may, or may not, present a higher passage risk to eels. Conversely, periods of low flow may be associated with a significant proportion of total river flow passing through turbine units, which present additional, or different, passage risk to eels. If discrete conditions which promote eel downstream migration are known, it may be possible to take actions with respect to project operations which reduce or minimize passage risk (i.e., operation of a bypass, reduction of intake approach velocities, directed spillage through a particular route at a project, etc). These studies should provide baseline information on river-specific downstream migration to predict when silver-phase eels are expected to migrate downstream in the West Branch, from which project operations could be modified to minimize passage risks.

***Methodology Consistent with Accepted Practice***
Quantification of downstream movements of American eels in river systems requires systematic sampling of migrants throughout the migratory season. This can be accomplished with traditional active trapping methods (i.e., fyke or stow net sampling, weirs, or eel racks). Passive monitoring of migrant eels using hydroacoustic methods offers an alternative to active trapping. However, this form of passive monitoring requires verification of potential acoustic targets with some level of active (collection) or visual (traditional optical or acoustic video) sampling.

The Applicant will need to identify at least two potential locations that offer opportunities to conduct simultaneous passive and active sampling. Each location will need to possess a route of downstream passage which conducts a significant proportion of river flow and each would need a proximal bypass equipped with a sampler so that fish can be concentrated/collected from the passage route and identified to species. Project operations will influence the relative proportion of flow (and thus numbers of downstream migrant eels) in each passage route, so numbers of eels sampled in each route represent only a proportion of the total number of eels migrating downstream within the entire river. Since the absolute proportion of eels using a specific route at any one time is unknown,

numbers of eels quantified within a route must serve as a relative index of the degree of migratory movement.

This study should quantify eel movements for two consecutive years since environmental conditions strongly influence migratory timing of eels, which can vary significantly from year to year (Haro 2003). Eels should also be measured during both study seasons, throughout the downstream passage season.

Eels should be quantified using methods similar to Haro et al. (1999), by continuously monitoring a fixed location at the projects with hydroacoustics. Since eels tend to concentrate in areas of dominant flow (Brown et al. 2009; EPRl 2001), the zone to be monitored should pass a dominant proportion of project flow throughout most periods of operation (i.e., forebay intake areas). Hydroacoustic monitoring shall encompass the entire potential migratory season, beginning in mid-August and ending in mid-December, and shall operate 24 hours per day. Data will be recorded for later processing and archiving.

Systematic active quantification of eels at downstream bypass samplers shall be performed simultaneously with passive hydroacoustic monitoring, to verify presence of eels and relative abundance of eel-sized hydroacoustic targets from the hydroacoustic data as well as the sizes of the eels collected.[1] Although daily operation of the bypass sampler could be performed, a more comprehensive technique is to monitor eels entering the bypass with an acoustic camera (i.e., DIDSON, BlueView, etc.). The acoustic camera will afford positive visual identification of eels as they enter the bypass, which is a concentration point for migrating eels. Acoustic camera monitoring will also allow monitoring to be performed 24 hours a day, and will be relatively unaffected by water turbidity (which influences effectiveness of traditional optical video monitoring). The acoustic camera system will be operated during the same time period as acoustic monitoring, and images will be recorded for later processing and archiving.

Data analyses of size of eels, hydroacoustic, acoustic camera, bypass sampling, and environmental/ operational data will follow standard methodology.

Each project's operations (flows, levels, gate openings, number of units operating and operation level) and environmental conditions (river flow, temperature, turbidity, air temperature, precipitation) will be monitored regularly (hourly measurements if possible) throughout the duration of the studies.

***Level of Effort/Cost, and Why Alternative Studies Will Not Suffice***

The level of cost and effort for the downstream migrant eel migratory timing study would be moderate, given the level of cost for instrumentation, deployment, and data review/analysis. Cost is estimated at $50,000 per year for the study. No alternatives are proposed.

**RE: Comments and Study Requests on Great Lakes Hydro America, LLC (GLHA) Notice of Intent to File License Application and Filing of Pre-Application Document for the Ripogenus Hydroelectric Project (FERC No. 2572) and Penobscot Mills Hydroelectric Project (FERC No. 2458)**

Dear Secretary Bose:

On June 11, 2021, you issued a Notice of Intent to File License Application, Filing of Pre-Application Document (PAD), Commencement of Pre-Filing process, and Scoping; Request for Comments on the PAD and Scoping Document, and Identification of Issues and Associated Study Requests for Great Lakes Hydro America, LLC's (GLHA) Ripogenus Project (FERC No. 2572) and Penobscot Mills Project (FERC No. 2458). The PAD contains the Licensee's presentation of information about the projects themselves and the environmental resources the Licensee states are affected by the projects.

As described in the scoping document, the Projects are located on the West Branch of the Penobscot River and Millinocket Stream in Piscataquis and Penobscot Counties, Maine. The Ripogenus Project is located about 47 river miles upstream of the confluence of the East Branch Penobscot River creating the 20.8 mile long, 29,270 acre impoundment that constitutes Ripogenus, Caribou, and Chesuncook Lakes and Black, Brandy, and Moose Ponds.

The Penobscot Mills Project consists of five dams; four hydropower developments (North Twin, Millinocket, Dolby, and East Millinocket) located between river miles 2 and 15 on the West Branch, and one storage development located on Millinocket Stream. The North Twin impoundment is at the upstream end of the Penobscot Mills Project. Controlled releases from the North Twin dam pass through three other dams and associated generation facilities of the Penobscot Mills Project, including the Millinocket, Dolby, and East Millinocket dams. The Millinocket Lake Storage Dam includes a pumping station where water can be pumped to Ambajejus Lake (within the North Twin impoundment) or discharged to Millinocket Stream via the Millinocket Lake Dam. Based on the descriptions in the PAD, it is our understanding that over the term of the current license, project operations have shifted from seasonal store and release to pulsing or peaking operations; pulsing and peaking operations result in significant changes to the environment compared to seasonal store and release.

Dams in the West Branch were directly responsible for the extirpation of diadromous fish, including Atlantic salmon (now endangered), that once flourished in the West Branch, as well as the destruction of their habitats (*see* Schmitt, 2015). Today, the Penobscot Mills Dams and the Ripogenus Dam are part of a network of dams in the West Branch that are directly responsible

for preventing sea-run fish from accessing the river, which prevents the restoration of these resources and their habitats. Furthermore, the reregulation of flows on the West Branch Penobscot at the Ripogenus and Penobscot Mills dams that are purportedly designed to dampen the variability and occasional extreme seasonal precipitation (GLHA 2021) affect Atlantic salmon designated critical habitats in the mainstem Penobscot and may impact survival of Atlantic salmon and other diadromous fish. The West Branch once provided high gradient, climate resilient, ecologically unique habitats in the Penobscot watershed that Atlantic salmon once thrived in, but these habitats are now inaccessible because of dams. Ecologically and economically important alosines used to inhabit the lower West Branch up to Shad Pond, while American eel and sea lamprey historically inhabited the majority of the West Branch. These species have been extirpated from the West Branch due to the construction and continued existence of dams without effective fishways. We highlight these impacts to form the basis of our comments and the studies that we are requesting.

We understand that the Commission will make a determination regarding the necessity of an Environmental Impact Statement (EIS) or Environmental Assessment (EA) pursuant to the National Environmental Policy Act (NEPA) after GLHA files its final license application. However, given the existing information on project effects to NMFS trust resources, FERC should analyze the impacts of the project through an EIS, rather than an EA, due to the complex nature of the project and its impacts. Comments on the PAD from many stakeholders, including expert testimony from Ed Spear, have made compelling arguments that these dams and their operations likely result in considerable negative ecological impacts to the West Branch Penobscot River. New flow and impoundment management regimes since the last relicensing can affect flows and water temperatures in the mainstem Penobscot that emanate into ecological impacts that may affect the endangered Gulf of Maine distinct population segment of Atlantic salmon and its designated critical habitat. This relicensing is also expected to generate significant public interest. For these reasons, there is sufficient information indicating that these projects affect important natural resources, and their relicensing constitutes a major federal action significantly affecting the quality of the human environment. Pursuant to your responsibilities under NEPA, FERC should conduct a full alternatives analysis that includes consideration of an alternative that would result in the decommissioning and removal of the Ripogenus and Penobscot Mills dams.

The Penobscot River including the West Branch, and the lands around it, are the homelands of the Penobscot Indian Nation (PIN). The PIN has depended on the river and the surrounding land for its natural resources and for transportation for thousands of years. The Penobscot name for the West Branch *Ketteteqwewick*, means “the main branch.” It was given this name because it was the canoe route to Mount Katahdin, which is the Tribe’s most sacred place (*www.penobscotnation.org*).

PIN is an important partner to the U.S. Fish and Wildlife Service and NMFS in efforts to restore and recover migratory fish species, including endangered Atlantic salmon, to the Penobscot River and its tributaries. We recognize the unique and distinctive relationship that exists between the United States and each Indian tribe including PIN, and strongly encourage FERC to work with the PIN to understand and fully consider their positions and interests regarding the potential continued operation of these projects.

We have reviewed the PAD and attended the scoping meeting on September 9, 2021. Our attached comments on the PAD and study requests emanate from our agency's authorities to protect, manage, and conserve the nation's living marine resources and associated habitats. The studies that we have identified are necessary to inform how these projects affect NOAA trust resources, including endangered Atlantic salmon in the mainstem Penobscot River and their critical habitat so that adverse impacts can be appropriately avoided or mitigated through license articles.

Specific studies that we are requesting are:

- Evaluate how the operations of the Penobscot Mills and Ripogenus Dam affects the hydrology of the West Branch and mainstem Penobscot River using an Indicators of Hydrologic Alteration Model
- Evaluate project effects on river temperature in the West Branch and mainstem Penobscot River
- A study to evaluate future flow and water temperature scenarios

If you have any questions or need additional information regarding our comments or study requests, please contact Dan Kircheis at dan.kircheis@noaa.gov.

Sincerely,

Jennifer Anderson

Jennifer Anderson
Assistant Regional Administrator
for Protected Resources

cc: Service List

**National Marine Fisheries Service's Comments and Study Requests on Brookfield Renewable's Pre-Application Document for the Ripogenus Hydroelectric Project (FERC No. 2572) and Penobscot Mills Hydroelectric Project (FERC No. 2458)**

1. Project Background

The Projects are located on the West Branch of the Penobscot River and Millinocket Stream in Piscataquis and Penobscot Counties, Maine. The Ripogenus Project is located about 47 river miles upstream of the confluence of the East Branch Penobscot River creating the 20.8 mile long, 29,270 acre impoundment that constitute Ripogenus, Caribou, and Chesuncook Lakes and Black, Brandy, and Moose Ponds.

The Penobscot Mills Project consists of five dams. Four hydropower developments (North Twin, Millinocket, Dolby, and East Millinocket are located between river miles 2 and 15 on the West Branch and one storage development is located on Millinocket Stream. The North Twin Impoundment is at the upstream end of the Penobscot Mills Project and receives flow from the Ripogenus Project. Controlled releases from the North Twin Development pass through three other developments and associated generation facilities of the Penobscot Mills Project, including the Millinocket, Dolby, and East Millinocket Developments. The Millinocket Lake Storage Development includes a pumping station where water can be pumped to Ambajejus Lake (within the North Twin impoundment) or discharged to Millinocket Stream via the Millinocket Lake Dam.

2. Federal Statutory Requirements

We are responsible for conservation, management, and protection of living marine and aquatic resources throughout jurisdictional river basins in coordination with other state and federal agencies, local governments, Indian tribes, fisheries commissions, and conservation organizations. Our authority to manage diadromous fish in these river basins comes from Congress. Specifically, Congress has directed us to manage diadromous species, including a grant of discretionary authority to us, to order fish passage at dams licensed by the Federal Energy Regulatory Commission. NMFS' congressionally mandated statutory authorities include the Federal Power Act, the Endangered Species Act, the Magnuson-Stevens Fishery Conservation and Management Act, the Atlantic Coastal Fisheries Cooperative Management Act, the Fish and Wildlife Coordination Act, and the National Environmental Policy Act.

*A. The Federal Power Act (FPA) (as amended)(16 USC §§791a, et seq.)*

Section 18 of the FPA expressly grants to the Department of Commerce (DOC) and the Department of the Interior authority to prescribe fishways. Section 18 of the FPA states that FERC must require construction, maintenance, and operation by a licensee at the licensee's own expense of such fishways, as may be prescribed by the Secretary of Commerce or the Secretary of the Interior. Within the DOC, the authority to prescribe fishways is delegated to the NMFS Regional Administrators.

Under Section 10(j) of the FPA, licenses for hydroelectric projects must include conditions to protect, mitigate damages to, and enhance fish and wildlife resources, including related spawning

grounds and habitat. These conditions are to be based on recommendations received from federal and state fish and wildlife agencies. FERC is required to include such recommendations unless it finds that they are inconsistent with Part I of the FPA or other applicable law, and that alternative conditions must adequately address fish and wildlife issues. Before rejecting an agency recommendation, FERC must attempt to resolve the inconsistency, giving due weight to the agency's recommendations, expertise, and statutory authority. If FERC does not adopt a Section 10(j) recommendation, in whole or in part, it must publish findings that adoption of the recommendation is inconsistent with the purposes and requirements of Part 1 of the FPA or other applicable provisions of law, and that conditions selected by FERC adequately and equitably protect, mitigate damages to, and enhance fish and wildlife and their habitats.

Resource agencies and tribes may also recommend conditions under Section 10(a)(1) of the FPA for the protection, mitigation, and enhancement of fish and wildlife (including related spawning grounds and habitat) consistent with a comprehensive plan.

### *B. Endangered Species Act (ESA) of 1973 (as amended) (16 USC §§1531, et seq.)*

The purpose of the ESA is to protect and recover imperiled species and the ecosystems upon which they depend. It is administered by the Department of Interior's U.S. Fish and Wildlife Service (USFWS) and the Commerce Department's NMFS. The USFWS has primary responsibility for terrestrial and freshwater organisms, while the responsibilities of NMFS are mainly marine wildlife, such as whales, and anadromous fish, such as salmon.

Under the ESA, species may be listed as either endangered or threatened. "Endangered" means a species is in danger of extinction throughout all or a significant portion of its range. "Threatened" means a species is likely to become endangered within the foreseeable future. All species of plants and animals, except pest insects, are eligible for listing as endangered or threatened. For the purposes of the ESA, Congress defined species to include subspecies, varieties, and, for vertebrates, distinct population segments.

Section 7(a)(1) of the ESA requires federal agencies to use their authorities to further the conservation of listed species. ESA section 7(a)(2) states that each federal agency shall, in consultation with the Secretary of Commerce or Interior, as appropriate, insure that any action they authorize, fund, or carry out is not likely to jeopardize the continued existence of a listed species or result in the destruction or adverse modification of designated critical habitat. Any discretionary federal action that may affect a listed species or its critical habitat must undergo ESA section 7 consultation. Issuance of a hydroelectric project license by the Commission is an action that may require ESA section 7 consultation.

### *C. Magnuson-Stevens Fishery Conservation and Management Act (MSA) (as amended) (MSA) (16 USC §§1801, et seq)*

The 1996 amendments to the MSA set forth a number of mandates for us, the Fishery Management Councils (Councils), and other federal agencies to identify and protect important marine and diadromous fish habitats. The Councils are required to identify and describe essential fish habitat (EFH) for all managed species in order to protect habitat from fishing impacts and to allow for consultation with federal agencies whose actions may adversely impact

EFH, which is defined as "those waters and substrates necessary to fish for spawning, breeding, feeding, or growth to maturity." 16 U.S.C. § 1853(a)(7) and § 1802(10). The MSA requires federal agencies to consult with the Secretary of Commerce, through us, with respect to "any action authorized, funded, or undertaken, or proposed to be authorized, funded, or undertaken, by such agency that may adversely affect any essential fish habitat identified under this Act." 16 U.S.C. § 1855(b)(2). In the EFH consultation process, the federal action agency initiates consultation by preparing and submitting a completed EFH assessment describing the potential impacts of the action on EFH.

*D. The Atlantic Coastal Fisheries Cooperative Management Act (ACFCMA) (as amended) (16 USC §§5101, et seq.)*

The purpose of the ACFCMA is to provide for more effective fishery resource conservation of coastal fish species that are distributed across the jurisdictional boundaries of the Atlantic States and the Federal Government. These coastal fish species, which include American Eel, shad and river herring, are managed by various species boards of the Atlantic States Marine Fisheries Commission, which develop fishery management plans and recommend management action to the states and NMFS.

*E. The Fish and Wildlife Coordination Act (FWCA) (as amended)* (16 USC §§661, *et seq*.)

The FWCA provides that fish and wildlife conservation shall receive equal consideration and be coordinated with other features of water resource development programs. A Federal action agency, such as the Federal Energy Regulatory Commission (FERC), shall consult with us with a view to the conservation of fish and wildlife resources by preventing loss of and damage to such resources as well as providing for the development and improvement thereof in connection with such water resource development. We may provide recommendations to the Federal action agency to which the action agency shall give full consideration.

*F. The National Environmental Policy Act (NEPA) (as amended)* (42 USC §§4321, *et seq*.)

NEPA and its implementing regulations require federal action agencies to analyze the direct and indirect environmental effects and cumulative impacts of project alternatives and connected actions. NEPA requires the federal action agency to conduct a comparative evaluation of the environmental benefits, costs, and risks of the proposed action, and alternatives to the proposed action.

3. NOAA Trust Resources

NOAA's NMFS is a trustee for coastal and living marine resources, including commercial and recreational fisheries, diadromous species, marine mammals, and marine, estuarine, and coastal habitat systems. Through management, conservation and recovery efforts, and public outreach and education under the Marine Mammal Protection Act and Endangered Species Act (ESA), we strive to ensure the survival of the protected marine species in the Northeast United States for

future generations. These projects occur within the historical range of federally listed Gulf of Maine (GOM) Distinct Population Segment (DPS) of Atlantic salmon; however, because of the construction of dams without fish passage, no fish species protected under the ESA occur in the West Branch Penobscot River above the Medway Dam, nor has any critical habitat been designated under the ESA. That said, before the construction of dams, the West Branch Penobscot supported ecologically, culturally, and commercially significant populations of sea-run fish, including Atlantic salmon, American shad, American eel, alewife and blueback herring (Houston et al. 2007). It is assumed the West Branch also supported sea lampreys (Houston et al. 2007) that provide a number of ecologically important functions.

Our work is guided by two core mandates – to ensure the productivity and sustainability of fisheries and fishing communities through science-based decision-making and compliance with regulations, and to recover and conserve protected resources through the use of sound natural and social sciences and compliance with regulations.

4. Protected Species and Designated Critical Habitat in the Project Area

The GOM DPS of Atlantic salmon is listed as endangered under the ESA (65 FR 69459 and 74 FR 29344). The GOM DPS includes all anadromous Atlantic salmon whose freshwater range occurs in the watersheds from the Androscoggin River northward along the Maine coast to the Dennys River. Included are all associated conservation hatchery populations used to supplement these natural populations. Atlantic salmon are jointly listed by NMFS and USFWS. Pursuant to a March, 2009 Statement of Cooperation between NMFS and USFWS concerning implementation of the ESA for endangered Atlantic salmon, NMFS has the lead for all section 7 consultations considering the effects of dams on the GOM DPS of Atlantic salmon and their designated critical habitat. The overarching goals of NMFS and USFWS with respect to endangered Atlantic salmon are to recover the species and *conserve* the ecosystem on which they depend. Accordingly, for these projects, we must ensure that any activities that may affect Atlantic salmon and its designated critical habitat are avoided or minimized to the extent practicable in order to *conserve* the ecosystems that salmon depend upon. As described above, the purposes of the ESA are "*to provide a means whereby the ecosystems upon which endangered and threatened species depend may be conserved, and to provide a program for the conservation of such endangered species and threatened species*" (ESA Sec. 2(b)). The ESA defines the terms "conserve," "conserving," and "conservation" to mean "*the use of all methods and procedures which are necessary to bring any endangered species or threatened species to the point at which the measures provided pursuant to this Act are no longer necessary*" (ESA Sec. 3(3)).

The West Branch Penobscot is within the historic range of the GOM DPS of Atlantic salmon. It is a sub-basin of the Penobscot River basin that accounts for approximately 25 percent of the entire Penobscot basin drainage area, and once provided substantial, ecologically important habitat that supported robust runs of Atlantic salmon (Fay et al. 2006). Historically, Atlantic salmon ranged throughout the West Branch as far as Penobscot Brook, a distance over 350 river km inland (Atkins, 1868). Today, the distribution of Atlantic salmon is limited by dams. Anadromous Atlantic salmon were extirpated in the West Branch in the late 1800s to early 1900s. While Atlantic salmon continue to persist in the mainstem Penobscot River, the Medway Dam in the lower West Branch (which has no upstream fish passage facilities) blocks further

passage into the West Branch. Even if Atlantic salmon could move up past the Medway Dam, the Penobscot Mills Project dams, that also have no fish passage, block further access into the watershed and prevent access to spawning and rearing habitat.

Absent dams, the West Branch would contain abundant, high quality Atlantic salmon habitat. The West Branch was not designated as critical habitat because it was not occupied by the species at the time of listing (i.e., because dams prevented access to the West Branch and had resulted in the loss of any anadromous Atlantic salmon in the river), and we determined that the habitat in the West Branch was not essential to achieving the recovery goals of the species (74 FR 29300, June 2009) because of abundant habitat elsewhere in the Penobscot watershed. It is important to note that this does not mean that if restoration of Atlantic salmon could be achieved in the West Branch that this would not be meaningful for the recovery of Atlantic salmon; we expect that such restoration would in fact contribute to achieving recovery goals and could help accelerate the recovery timeline and improve the resilience of the DPS. However, restoration of Atlantic salmon in the West Branch is not as simple as merely providing fish passage at these projects. In order to reach suitable habitat in the upper reaches of the West Branch, upstream fishways would need to be constructed at five dams on the river. It is likely that even if state-of-the-art fishways were installed, the cumulative effect of direct and delayed mortality that both smolts and adults would experience passing through a minimum of eight dams (five West Branch dams and three mainstem dams) would come at a far greater cost to the population than if these fish are excluded from entering the West Branch in hopes that they continue to seek out high valued, unobstructed habitats in the East Branch of the Penobscot River (*See* Stich et al. 2015). In our view, the removal of multiple dams and the restoration of anadromous Atlantic salmon in the West Branch would provide a clear conservation benefit to the GOM DPS as a whole, and should be fully considered in the NEPA process.

Finally, these dams and associated impoundments and the operations of these dams significantly alter the natural flow regime of the West Branch Penobscot. Given the size of the West Branch, the size of the impoundments created by these dams, and the substantial flow modifications associated with the Ripogenus and Penobscot Mills Projects (GLHA 2021), one can reasonably assume that the effects of these projects and their operations extend into the mainstem Penobscot. Altering natural flow regimes, including the timing, frequency, or duration of natural flow events can reduce habitat diversity, disrupt migration and spawning cues for fish, and alter the survival and distribution of juvenile fish and macroinvertebrates (Meridian 2004). Furthermore, changes in streamflow, including dam impoundments and flow management through dams, significantly affect water temperatures due to changes in thermal capacity (Webb et al. 2003). Water temperature is especially important for Atlantic salmon given that they are poikilothermic (i.e. their body temperatures and metabolic processes are determined by temperature). Temperature is a stimulant for salmon migration, spawning, and feeding (Elson 1969). Temperature also significantly influence egg incubation success or failure, food requirements and digestive rates, growth and development rates, vulnerability to disease and predation, and may be responsible for direct mortality (Garside 1973; Spence et al. 1996; Peterson et al. 1977, Whalen et al. 1999).

Given the nature of these impacts, the flow alterations attributed to the Penobscot Mills and Ripogenus projects likely affect designated Atlantic salmon critical habitat and may affect Atlantic salmon survival and recovery.

5. NOAA Comments on the PAD

**Comment 1.** Penobscot Scoping Document Section 3.4.3 - Project Decommissioning

In section 3.4.3 of the scoping document, FERC states that it is not considering decommissioning as an alternative to these projects as they have no record that demonstrates serious resource concerns that cannot be mitigated if the projects are relicensed. The Commission is fully aware that the construction of the Penobscot Mills and Ripogenus Projects extirpated runs of anadromous species in the West Branch of the Penobscot River. We are also confident that the Commission is fully aware *at this time* that relicensing the projects will result in the continued extirpation of these species in the river absent bold actions such as dam decommissioning and removal. These projects represent a significant natural resource concern that should be fully evaluated within the NEPA process, including an alternatives analysis that considers the decommissioning and removal of the Ripogenus and Penobscot Mills dams. The information that would come from such an alternatives analysis is necessary to provide state and federal agencies and the public the information they need to fully understand the economic, environmental, and social opportunities/costs of the West Branch both with and without the dams associated with these projects. The Recovery Plan for the GOM DPS of Atlantic salmon (2019) lists dam removals as one of the threats-based criteria necessary to eliminate the threat of extinction and support a recovered GOM DPS of Atlantic salmon. Dam removal is also a specific recovery action for increasing the carrying capacity for Atlantic salmon to support a growing and self-sustaining population. Furthermore, we note that project decommissioning with dam removal is the only alternative that could *adequately* mitigate the threat to sea-run fish posed by these Projects as there are no plausible engineering solutions available today that could allow for both continued existence of the projects and restoration of sea-run fishes in the West Branch. As such, we recommend the Commission include project decommissioning with removal as a reasonable alternative to be considered in its NEPA analysis.

The dams associated with these projects are part of a network of dams in the West Branch that were directly responsible for the extirpation of diadromous fish, including Atlantic salmon (now endangered), that once lived in the West Branch, as well as the destruction of their habitats (*See* Schmitt, 2015). Today, these dams are directly responsible for preventing sea-run fish from accessing the river, preventing the restoration of these resources and their habitats. Action C2.4 of the *Final Recovery Plan for Atlantic Salmon* (USFWS & NMFS 2019) states that when feasible, hydro-electric dams that block habitats that afford significant conservation benefits to Atlantic salmon and their ecosystems should be removed. Although the West Branch is not part of Atlantic salmon's designated critical habitat and was determined in 2012 (74 FR 29300) to not be essential to the conservation of the species, it does contain significant habitats that, if the dams were removed, it could contribute significantly to the conservation of the species. At present, we are not aware of any engineered fish passage solutions that could be implemented at the Penobscot Mills and Ripogenus project dams that would allow for sufficient survival of Atlantic salmon such that passage into the West Branch would provide a conservation benefit to the species. This is a consequence of the number of dams associated with Penobscot Mills and Ripogenus projects in combination with the dams on the mainstem Penobscot that Atlantic salmon would have to pass through in order to access spawning and nursery habitats. The same impacts may be true for other sea-run fish as well, particularly American shad, where the cumulative impacts of dams severely impact survival and spawning success. The extirpation of

sea-run fish by these dams, the exclusion of sea-run fish caused by the dams under these licenses, and the fact that there are no plausible engineered fish passage solution that would afford a conservation benefit to Atlantic salmon, represent serious natural resource concerns that may not be able to be appropriately mitigated if the projects are relicensed.

Given that dam removal has never been considered or evaluated for these projects, we contend that FERC has responsibilities under NEPA to evaluate decommissioning and dam removal as an alternative during this relicensing. This is necessary to strike an appropriate balance among the many competing developmental and non-developmental interests (including conservation interests) in the West Branch. This evaluation will provide the public and resource agencies the necessary information to fully evaluate the effects of these dams on public resources.

**Comment 2:** Scoping Document Section 5.0 - Description of Existing Environment and Resource Impacts

In the June, 2021 PAD, GLHA claims that "A significant body of information presently exists relative to the Ripogenus and Penobscot Mills Projects; even so, GLHA understands that some level of additional study or information gathering may be necessary in support of the application for new licenses." We agree with GLHA that additional study and information gathering is necessary, but attribute little value to the existing information which is more than thirty years old. Additional fisheries data must be collected as part of this relicensing to adequately describe the projects' effects on existing fisheries resources in the project areas and downstream of the projects. Despite the fact that nearly all of the information concerning existing environmental resources presented in the PAD was collected over thirty years ago during the last relicensing, GLHA does not propose a single fisheries related study as part of this relicensing. As an example of the limitations of relying on non-contemporary data to describe existing fisheries resources, Table 5.4-3 in the PAD indicates that smallmouth bass do not occur in North Twin Lake or Quakish Lake. This is not accurate. Smallmouth bass are known to presently inhabit each of these water bodies (personal communication, Kevin Dunham, MDIFW, September 30, 2021). The MDIFW first documented smallmouth bass in North Twin Lake in 2005 (personal communication, Kevin Dunham, MDIFW, September 30, 2021). The fisheries resources of the West Branch of the Penobscot River have changed dramatically over the last 30 years including the colonization of smallmouth bass into the Pemadumcook chain of lakes, and the decline of American eel throughout most of their range (Shepard 2015). These impacts to the fisheries resources in the project areas are undoubtedly exacerbated by these dams, their operations, and the associated impoundments. It is incumbent on FERC and GLHA to collect the necessary data to accurately and thoroughly document the fisheries resources in the Penobscot Mills and Ripogenus Projects areas.

**Comment 3:** Scoping document 3.1.4 and PAD Table 6.1-2 and 3 (Environmental measures for aquatic resources and Potential Project Effects)

The Table of Potential Project Effects (Table 6.1-2 and 3) does not describe project impacts to sea-run fish in the mainstem of the Penobscot, including endangered Atlantic salmon and their designated critical habitat. These impacts need to be fully characterized as the information will be necessary for the formulation of license articles. GLHA indicates in Vol. 1 of the PAD (Section 1.6) that the Project storage impoundments are "*managed on an annual cycle to dampen the variability and occasional extremes of seasonal precipitation and runoff through storage*

*within the impoundments. This storage allows for continuous flows to downstream aquatic habitat and spawning areas within the West Branch and the mainstem of the Penobscot River during times of lower inflows to the system. In addition, the storage allows flows from the West Branch to be reduced during higher seasonal flow periods when the combined flows from the East and West Branches have the potential to adversely impact human life, property, and environmental resources downstream along the mainstem Penobscot River."* As the effects of project operation are expected to extend into the mainstem, where several of our trust species occur, any analysis of project effects must include effects to species in the mainstem and associated habitats.

**Comment 4:** Scoping Document 3.1.3 Project Operation

There appears to be discrepancies regarding the descriptions of current operations of the Penobscot Mills and Ripogenus Projects. In the August 2021 Scoping Document 1, the Commission describes operation of the Ripogenus Project as "store-and-release facility with an annual seasonal drawdown that allows for management of water levels and flows downstream of the project." The Commission also describes the operation of North Twin and Millinocket Lake Storage as "store and release developments."

On p. 13 in the PAD for the Ripogenus and Penobscot Mills Project (Volume 1 of 2) GLHA states:

> *In addition to these considerations, the need for power, grid stability, and reliability are also important aspects GLHA will promote in these relicensing proceedings. Peak demands for power can vary greatly depending on the time of day and from season to season.* ***Hydropower facilities that have peaking ability*** *(emphasis added) or other operational flexibility provide not only a reliable source of renewable and carbon-free energy to the grid, but they are also needed and used to maintain the balance between electricity supply and demand. The flexibility and storage capacity of hydropower supports continued development of intermittent renewable energy sources, such as solar or wind, by providing quick responses to changes in output. The base-load energy and grid stability provided by hydropower is very different than, and wholly complimentary to, that provided by solar or wind energy.*
>
> *The electrical output from the Projects is sold to the New England wholesale electricity market administered by the Independent System Operator of New England (ISONE). The Projects generate carbon-free, renewable power and* ***provide peaking and variable output generation*** *(emphasis added) of value to the grid. Power from the Projects helps meet the Nation's and regional carbon reduction goals, reduces reliance on natural gas to meet sudden changes in demand, and facilitates adoption of other intermittent renewable energy sources.*

On p. 1-15 of the PAD, GLHA states:

> *If the existing flexibility, operational ranges, or* ***peaking capabilities*** *(emphasis added) of the Projects as presently licensed were further limited or curtailed, the ISONE would need to rely more heavily on natural gas burning facilities to meet peak power demands now and into the foreseeable future.*

During the Commission's agency and NGO scoping meeting on September 9, 2021, the Licensee stated that neither the Ripogenus nor Penobscot Mills operate as peaking facilities. We understand that a licensed peaking operation would permit a Licensee to shift generation to times of greater energy demand and thus higher operating revenues. The Commission should immediately review operations data for the Ripogenus and Penobscot Mills Project to determine the exact mode of operation for these projects, and if necessary, update Scoping Document 1 to accurately describe these operations.

The PAD suggests that there have been no changes in operations since the last relicensing and that therefore the licensee is not considering the collection of any additional fisheries data as part of this relicensing. However, as we have detailed above, there are several instances in the PAD where GLHA indicates that peaking is now a component of project operations of these dams, which is a change in operation since the last relicensing. Given that the PAD does not provide clear evidence to demonstrate that there actually have been no changes in the project operations since the last relicensing (as they describe), we request that GLHA conduct an analysis that contrasts current operations of the projects with historical operations under GNP ownership to support the claim that project operations have not changed as purported in the PAD. This includes contrasting daily seasonal impoundment levels and average daily discharge (daily minimum, maximum, and average) at all developments for the last ten years. In particular, GLHA should contrast daily minimum and maximum flows below McKay Station and North Twin Development to determine if the current range of discharges is similar to operations under the previous owner. This information will inform what additional information is necessary to determine impacts from operations to environmental resources including designated critical habitat in the mainstem which was not considered 30 years ago. We believe this data should have been provided in the June, 2021 PAD and should be submitted to us as part of the Proposed Study Plan. Raw data used in this analysis must be provided to NMFS in electronic form for our review.

**STUDY REQUEST 1:** A Study to Evaluate the Effects of Operating the Penobscot Mills and Ripogenus Dams on the Hydrology of the West Branch and Mainstem Penobscot River Using an Indicators of Hydrologic Alteration Model (IHA)

Study Goals and Objectives

Within the June 11, 2021, PAD for the Penobscot Mills Project and Ripogenus Project, the existing, relevant, and reasonably available information is insufficient in identifying potential adverse effects of project operation on a number of associated aquatic resources, including endangered Atlantic salmon and other diadromous fish communities. Potential project effects that require additional analysis include:

- Seasonal effects of project operations on flows in the West Branch of the Penobscot River downstream to the Mattaceunk Project that may affect federally listed Atlantic salmon and their designated critical habitat;
- Seasonal effects of project operation on flows in the West Branch of the Penobscot River downstream to the Mattaceunk Project that may impact survival of sea-run fish communities, including alosines, American eel, and sea lamprey;

- Consistency of project operations and reservoirs to protect state and federal water quality standards;
- Effects of the project on instream habitat in project-affected streams including minimum flows, peak flows, and ramping rates; and,
- Effects of the project on access to tributaries downstream of the projects.

The goal of this study is to develop the essential additional information to inform the nature, scope, and scale of these potential project effects. The specific information to be developed is the unimpaired[1] and regulated flow regimes for the affected reaches of the West Branch of the Penobscot River and to inform impoundment levels and operational management of dams, both individually and in the aggregate, that are protective of fish, water quality, riparian habitat, and other ecosystem functions. Specifically, the licensee should detail how the their dams, impoundments and operations currently modify hydrologic variables, including magnitude, timing, frequency, duration and rate of change in West Branch of the Penobscot River down to the Mattaceunk Project so that FERC can evaluate how these hydrologic regime modifications impact sea-run fish, including Atlantic salmon, and their habitats in order to develop license articles.

The objective of this study request is not to have FERC consider "pre-project" conditions in the analysis for this relicensing. Rather, the objective of the study is to inform future license conditions that are protective of aquatic resources in the West Branch of the Penobscot River and areas downstream of the projects that are affected by project operations by contrasting what current conditions are with conditions that are protective of aquatic resources.

Existing Information

GLHA specifically states in Volume 1 of the PAD, Section 1.6, that the impoundments and operations are used to modify flows in the mainstem Penobscot River. Specifically, "*The Project storage impoundments are managed on an annual cycle to dampen the variability and occasional extremes of seasonal precipitation and runoff through storage within the impoundments. This storage allows for continuous flows to downstream aquatic habitat and spawning areas within the West Branch and the mainstem of the Penobscot River during times of lower inflows to the system. In addition, the storage allows flows from the West Branch to be reduced during higher seasonal flow periods when the combined flows from the East and West Branches have the potential to adversely impact human life, property, and environmental resources downstream along the mainstem Penobscot River.*"

GLHA acknowledges that operation of the Penobscot Mills and Ripogenus Projects affects the mainstem of the Penobscot River. Project impoundments and flow management that affect flows in the mainstem may have direct effects on sea-run fish, including endangered Atlantic salmon, and therefore a full analysis of project effects on flows in the mainstem should be conducted.

[1] Unimpaired is the flow that is produced by the basin in its current state, but, without dams and diversions (California Department of Water Resources, Bay-Delta Office 2016).

As indicated in Volume 1 of the PAD, during the previous relicensings of the projects, a Water Use Plan (WUP) was developed that identified proposed operations of the projects that intended to balance and manage multiple competing water uses (e.g., power generation, recreation, fisheries, minimum flows, flood control). Inherent to the WUP model was the goal to maximize energy production for two, now defunct, paper mills in the Towns of Millinocket and East Millinocket. These paper mills closed in the mid-2000s. Since power generated at the Penobscot Mills and Ripogenus Projects is no longer used exclusively by the Millinocket and East Millinocket paper mills but is instead used to maximize generation output to ISO New England, past assumptions on water use at the projects are no longer relevant to current operations (e.g., stable electrical generation and demand, dilution of effluent produced by the mills). Also, the WUP was not intended or constructed to assess the effects of the projects throughout the West Branch of the Penobscot system. The WUP only investigated selected major storage reservoirs in the project area. The WUP did not consider the Millinocket Storage Project and it relied on a weekly time step which is not appropriate under current peaking operations. The WUP was used by FERC during the last relicensings to solely "evaluate the feasibility of providing alternative flows using available water" with an emphasis on maximum energy production and dilution of effluent at the two paper mills (FERC 1996). In evaluating the function of the WUP, FERC stated "Staff is not aware of any other water use model currently in use that contains a habitat evaluation module; habitat analyses are usually conducted with IFIM, independently of any hydrologic or hydraulic model." Clearly, as outlined below, this is no longer the current state of science. Furthermore, in the scoping document 3.1.4 and PAD Table 6.1-2 and 3, the proposed environmental measures for aquatic resources do not describe measures to protect sea-run fish nor does the Table of Potential Project Effects describe project impacts to sea-run fish, including federally endangered Atlantic salmon or its critical habitat.

Nexus between the Projects and Resource to be Studied and How the Results Will Be Used

Project operation, and maintenance activities directly and indirectly affect hydrology throughout all of the West Branch of the Penobscot River and the mainstem Penobscot (as described in the PAD, Vol. 1, Section 1.6). The results of this study will be used in conjunction with the results of other, resource-specific studies to evaluate potential project effects and to develop management measures and license articles that may be employed to address those effects.

Study Area and Study Sites

The study area includes: (1) the impoundment created by Ripogenus Dam including Ripogenus, Caribou, and Chesuncook Lakes and Black, Brandy, and Moose Ponds; (2) the West Branch of the Penobscot River from McKay Station to its confluence with Ambajejus Lake including the Holbrook Rearing Channel; (3) Millinocket Lake Storage Project and Millinocket Stream; (4) Ambajejus, Pemadumcook, North Twin, and South Twin Lakes; (5) the West Branch River below North Twin Development Dam; (6) the West Branch of the Penobscot River from the Back Channel below Stone Dam downstream to its' confluence with the mainstem Penobscot River, and (7) the mainstem Penobscot River downstream to the Penobscot Bay estuary.

According to the PAD, several developments in the Penobscot Mills Project (North Twin Development Dam) and the Ripogenus Project (McKay Station) operate in a peaking mode as part of their store-and-release license conditions. The Millinocket, Dolby, and East Millinocket

Development dams, although run-of-river facilities, operate in response to peaking inflows from the North Twin Project; thus, outflows of these dams also fluctuate similarly to peaking facilities.

There are no actual flow gages in the Ripogenus and Penobscot Mills Project areas. We understand that GLHA uses generation records to estimate stream flows. It is not known how accurate these estimates are in relationship to actual instantaneous flows below the projects. In order for the FERC to use these streamflow estimates as part of this relicensing, GLHA will likely need to conduct index testing to verify the accuracy of flow estimates at the Ripogenus and Penobscot Mills projects. The testing will verify existing efficiency curves at both projects. Otherwise, FERC should require GLHA to install streamflow gages below each project consistent with USGS methodology.

Hydrologic records maintained by GLHA and the previous Licensee from 1980 to 2021 will need to be compiled so that unimpaired flow can be determined for the West Branch of the Penobscot River. To develop the regulated and unregulated hydrological database for the Project, two different methods could be used: summation and proration. Given the lack of steam flow gages at the projects, summation cannot likely be used for this study. Rather, Licensee's operations data will likely be used to compute the unimpaired daily average flows for the study period.

Analysis

It is well documented that seasonal and inter-annual hydrologic variation is a dominant factor influencing ecological communities of river systems and that existing communities develop over time in response to the long-term hydrological patterns that occur (Meridian 2004). Altering the timing, frequency, or duration of naturally occurring flow events can reduce habitat diversity, disrupt migration and spawning cues for fish, and alter the survival and distribution of juvenile fish and macroinvertebrates (Meridian 2004). In general, the life history of all aquatic organisms has adapted to naturally occurring seasonal flow regimes. Based on this premise, the Indicators of Hydrologic Alteration (IHA) and Range of Variability Approach (RVA) methods were developed as part of the Nature Conservancy Freshwater Initiative (Meridian 2004; Richter et al. 1996, 1997). The IHA method provides a hydrologic analysis technique that considers the overall hydrological requirements of the system, rather than specific objectives such as a short list of species or geomorphic processes (Meridian 2004). In addition, the model defines an unimpaired hydrologic regime that is more likely to maintain or restore the natural biotic composition, structure, and function of the river system (Meridian 2004). The RVA method was subsequently developed to provide a tool that establishes flow targets based on the results of IHA analysis and goals for meeting resource objectives (Meridian 2004).

There are 32 statistical metrics that focus on descriptors of the streamflow regime that are considered to be important to the biological and physical integrity of a river. The 32 metrics derived in the IHA analysis can be clustered into five specific groups, which can then be used to assess potential environmental impact. The five groups for the IHA metrics, which are identified in the IHA protocol as described by Richter et al. (1996, 1997, and 1998), are as follows: 1) magnitude of monthly water conditions; 2) magnitude and duration of annual extreme water conditions; 3) timing of annual extreme water conditions; 4) frequency and

duration of high and low pulses; and 5) rate and frequency of change in water conditions.

Using the results of the IHA analysis, the Licensee should identify target flows and impoundment levels using the RVA described by Richter et al. (1997). The RVA approach identifies annual river management targets using the results of an IHA analysis approach for setting target flows in streams (Meridian 2004; Richter et al. 1997). The RVA approach is a river reach- or river basin-scale approach that establishes target flows for river management according to the natural (unimpaired) hydrologic regime in a river system (Meridian 2004). These management targets can then be used to help develop and implement river management strategies such as reservoir operations or stream diversions (Meridian 2004). The RVA analysis begins with a comprehensive characterization of ecologically-relevant attributes of a flow regime using the IHA approach, then uses the results to develop a flow regime that should maintain or restore the integrity of the subject river system (Meridian 2004). The method has six steps for setting, implementing, and refining flow targets and rules as presented in Richter et al. (1997).

For these reasons, we are requesting this study to evaluate the potential effects of project operation on a number of associated aquatic water resources, including endangered Atlantic salmon and other diadromous fish communities.

Study Plan Criteria

1. The goal of this study is to evaluate the effects of the Penobscot Mills and Ripogenus Projects on the hydrology in the West Branch of the Penobscot River, as well as the mainstem Penobscot River downstream to the estuary. Operation of the projects on the West Branch undoubtedly affect the timing and magnitude of flows (PAD Vol. 1, Section 1.6) in the mainstem Penobscot River and may affect the physical and biological features of the Migration Primary Constituent Element of designated critical habitat for Atlantic salmon. The results of this study will be used to establish baseline hydrologic conditions, project monitoring and assessment, development and analysis of alternatives for proposed project hydrology, potential mitigation measures, and planning additional instream flow studies as part of this relicensing. The objective of this study is to characterize metrics of hydrologic alteration due to project operational effects and then identify target flows and impoundment levels using the RVA method. The study will evaluate the following:

    - Seasonal effects of project operations on flows in the West Branch of the Penobscot River to the estuary that may affect federally listed Atlantic salmon and their designated critical habitat;
    - Seasonal effects of project operation on flows in the West Branch of the mainstem Penobscot River to the estuary that may impact survival of sea-run fish communities, including alosines, American eel, and sea lamprey;
    - Consistency of project operations and reservoirs to protect state and federal water quality standards;
    - Effects of the project on instream habitat in project-affected streams including minimum flows, peak flows, and ramping rates; and,

- Effects of the project on access to tributaries downstream of the projects.

2. NMFS is a federal resource agency with a mandate to protect and conserve fisheries resources and associated habitat. Resource management goals and plans are codified in our regulations and governing statutes. We rely on the best available data to support conservation recommendations and management decisions. This study is an appropriate request for the pre-application period.

3. The requestor, NMFS, is a federal resource agency.

4. Currently, we have little information on the effects on the current mode of operating the Penobscot Mills and Ripogenus Projects on the ecosystem of the West Branch and mainstem of the Penobscot River. Data collected during the past relicensing is not applicable to this relicensing since the mode of operation has changed from powering paper mills to maximizing electrical output to ISO New England. Contemporary data on inflows, reservoir level management, and project discharge is necessary to inform an IHA to provide meaningful information on the degree to which the hydrology of the West Branch of the Penobscot River to the estuary continues to be altered as a result of project operations and to inform license articles related to the minimization of effects on fisheries resources.

5. Project operations directly affect the habitat in the West Branch of the Penobscot River as well as the mainstem Penobscot River. The storage of water in the large reservoirs created by the Ripogenus, North Twin, and Millinocket Dams substantially changes the hydrologic conditions in the river downstream of the project by altering the timing and magnitude of spring flows in the watershed. Migratory fish rely on hydrologic cues to aid them in their migration. Rapid changes and multiple changes in flow can impact resident and migratory fish behavior, spawning, and rearing, as well as food production. The results of this study will be used to determine the necessity and scope of potential protection, mitigation, and enhancement measures, as well as provide sufficient information that can be used to evaluate the effects of the project on Atlantic salmon and their critical habitat.

6. In order to assess the impacts of flow regulation on Project-affected streams, flow characteristics will be computed and comparison tables prepared for the regulated and unimpaired flow conditions on the stream locations within the study area. Then, the IHA methodology will be applied to assess the effects of regulated flows on aquatic resources (Richter et al. 1996). Richter suggests that the hydrologic attributes of a stream can be described by five fundamental groups of statistics:

   Group #1: Magnitude of monthly water conditions
   Group #2: Magnitude and duration of annual extreme water conditions
   Group #3: Timing of annual extreme water conditions
   Group #4: Frequency and duration of high and low pulses
   Group #5: Rate and frequency of change in water conditions.

Once the IHA model is developed, the Licensee, in consultation with state and federal resource agencies and the Penobscot Indian Nation, will use the RVA approach to help develop and implement river management strategies such as target flows and reservoir operations that are protective of aquatic resources.

7. This study would require a desktop analysis. The preliminary estimated cost for the study, broken down by major tasks, is as follows:

| | |
|---|---|
| Research and Data Compilation | $50,000 |
| Analysis | $65,000 |
| Reporting | $50,000 |
| Total ……. | $165,000 |

We note the Commission has approved similar study request using the IHA and RVA methods during the relicensing of the following FERC licensed projects: Jackson (WA) (P-2157); McCloud-Pit (CA) (P-2106); Drum-Spaulding/Yuba-Bear (CA) P-2310, P-2266, P-2784; Merced (CA) (P-2179); Snohomish County PUD No.1 (WA) (P-14295); Bucks Creek (CA) (P-619); Skagit (WA) (P-553); Phoenix (CA) (P-1061)

**STUDY REQUEST 2:** A Study to Evaluate Project Effects on River Temperature in the West Branch and Mainstem Penobscot River

Study Goals and Objectives

GLHA specifically states in Volume 1 of the PAD, Section 1.6, that the impoundments and operations are used to modify flows in the mainstem Penobscot River. Dams and their impoundments significantly reduce river flow that can increase warming. Given that the West Branch drains 24% of the entire Penobscot Basin (NMFS, 2009) and approximately 57% of the river is impounded by dams (USACOE, 1990), the dam impoundment and operations that modify flows in the mainstem Penobscot, may also modify water temperatures that could affect survival of sea-run fish, including endangered Atlantic salmon.

Existing Information

The controlled releases designed to "dampen the variability and occasional extremes of seasonal precipitation" in the West Branch and mainstem Penobscot River (Penobscot PAD Vol. 1) directly affect Atlantic salmon critical habitats in the mainstem Penobscot that may directly impact survival of Atlantic salmon and other diadromous fish. Dams and their impoundments significantly reduce river flow that can increase warming. Changes in streamflow, including dam impoundments and flow management through dams, significantly affect water temperatures due to changes in thermal capacity with water temperature being inversely related to discharge (Webb et al. 2003).

Water temperature is one of the most important environmental factors affecting all forms of aquatic life in rivers and streams (Annear et al. 2004). Temperature is especially important for Atlantic salmon given that they are poikilothermic (i.e. their body temperatures and metabolic processes are determined by temperature). Temperature can be a stimulant for salmon migration,

spawning, and feeding (Elson 1969). Temperature can also significantly influence egg incubation success or failure, food requirements and digestive rates, growth and development rates, vulnerability to disease and predation, and may be responsible for direct mortality (Garside 1973; Spence et al. 1996; Peterson et al. 1977, Whalen et al. 1999).

Nexus between project operations and effects

The controlled releases designed to "dampen the variability and occasional extremes of seasonal precipitation" (GLHA 2021) may directly affect the physical and biological features of the Migration Primary Constituent Element of designated Atlantic salmon critical habitat in the mainstem Penobscot and may directly impact survival of Atlantic salmon and other diadromous fish. The combined effect of a warming climate along with altered stream flows can negatively affect the reproductive success of salmonids (e.g. Mantua *et al*. 2010).

Study Area and Study Sites

The study area includes: (1) the impoundments created by Ripogenus (2) the West Branch of the Penobscot River from Ripogenus Dam to the Medway Dam, including all the impoundments created by the Penobscot Mills Project (3) the West Branch of the Penobscot River from the Medway Dam downstream to its' confluence with the mainstem Penobscot River, and (4) the mainstem Penobscot downstream to the Penobscot Bay estuary.

Analysis

Specific information that needs to be collected as part of the study are:

- Model the seasonal effects of the Project's impoundments and flow modifications on the West Branch and mainstem Penobscot river water temperatures compared to river water temperatures if the West Branch were unimpaired by dams. The study area includes: (1) the impoundment created by Ripogenus Dam including Ripogenus, Caribou, and Chesuncook Lakes and Black, Brandy, and Moose Ponds; (2) the West Branch of the Penobscot River from McKay Station to its confluence with Ambajejus Lake including the Holbrook Rearing Channel; (3) Millinocket Lake Storage Project and Millinocket Stream; (4) Ambajejus, Pemadumcook, North Twin, and South Twin Lakes; (5) the West Branch River below North Twin Development Dam; (6) the West Branch of the Penobscot River from the Back Channel below Stone Dam downstream to the mainstem Penobscot River at the Mattaceunk Project (P-2520), and the mainstem of the Penobscot down to Milford Dam.
- Thermal profile of the Ripogenus and North Twin impoundments
- Development of an alternatives analysis to provide information on the efficacy of potential PM&E measures related to project effects on stream temperature, including, but not limited to: flow management, variable depth deep water turbine intakes, and impoundment management.

Study Plan Criteria

1. The goal of this study is to evaluate the project's effects on river temperature in the West Branch and mainstem Penobscot River.

2. NMFS is a federal resource agency with a mandate to protect and conserve fisheries resources and associated habitat. Resource management goals and plans are codified in our regulations and governing statutes. We rely on the best available data to support conservation recommendations and management decisions. This study is an appropriate request for the pre-application period.

3. The requestor, NMFS, is a federal resource agency.

4. Currently, there is no information on the effects of operating the Penobscot Mills and Ripogenus Projects on ambient river temperatures in the West Branch of the Penobscot River or mainstem Penobscot River. This information is necessary for us to inform potential license requirements to minimize the effects of operating the projects on temperatures to ensure appropriate operational measures and procedures are in place to afford necessary protections of sea-run fish and their ecosystems.

5. The controlled releases designed to dampen the variability and occasional extremes of seasonal precipitation (GLHA 2021) may directly affect the physical and biological features of the Migration Primary Constituent Elements of designated Atlantic salmon critical habitat in the mainstem Penobscot, and may directly impact survival of Atlantic salmon and other diadromous fish. The operations of the Penobscot Mills Projects and Ripogenus Dam reduce the magnitude and frequency of flow variability throughout the Penobscot River (GLHA 2021). Changes in streamflow, including dam impoundments and flow management through dams, significantly affect water temperatures due to changes in thermal capacity with water temperature being inversely related to discharge (Webb et al. 2003). The combined effect of a warming climate along with altered stream flows can negatively affect the reproductive success of salmonids (e.g. Mantua et al. 2010).

6. The procedures for modelling stream temperature are consistent with generally accepted scientific practice necessary to inform license conditions. Modelling the seasonal effects of flow modifications and conducting a thermal profile of the impoundments will provide necessary information to garner project effects on water temperature and mitigation measures that can be taken to offset those effects. A summary of the information and findings gained from this effort will be included in the application for new license. The information gathered from this modeling exercise will be used to assess potential effects on Atlantic salmon critical habitat, Atlantic salmon and other diadromous fish communities in the Project Area including the mainstem of the Penobscot and will help inform license articles.

7. This study would require a desktop analysis. The preliminary estimated cost for the study, broken down by major tasks, is as follows:

| | |
|---|---|
| Research and Data Compilation | $50,000 |
| Analysis | $65,000 |
| Reporting | $50,000 |

Total ……..... $165,000

**STUDY REQUEST 3:** A Study to Evaluate Future Flow and Water Temperature Scenarios

Goals and Objectives

GLHA specifically states in Volume 1 of the PAD, Section 1.6 that the impoundments and operations are used to modify flows in the mainstem Penobscot River potentially exacerbating the effects of climate change. For example, storage of water during the springtime may reduce survival rates of emigrating Atlantic salmon smolts in the lower reaches of the Penobscot River. Dams and their impoundments slow the rate of water moving through a river and subject Atlantic salmon smolts to altered temperature regimes that can have significant biological consequences (Angilletta Jr. et al. 2008). Changes in streamflow, including dam impoundments and flow management through dams, significantly affect water temperatures due to changes in thermal capacity with water temperature being inversely related to discharge (Webb et al. 2003). The combined effect of a warming climate along with altered stream flows can negatively affect the reproductive success of salmonids (e.g. Mantua *et al*. 2010). Furthermore, though there is some uncertainty in forecasting future climate conditions, there is no uncertainty that the climate in Maine is warming and will continue to warm, and as a consequence, precipitation types, rates, and duration will also change (*see* Fernandez et al. 2020). Thus, the licensee should evaluate a number of plausible future climate scenarios and how their dams and operations may affect these future scenarios to ensure appropriate operational measures and procedures are in place to afford necessary protections to sea-run fish and their ecosystems. Given that the West Branch drains 24% of the entire Penobscot Basin (NMFS, 2009) and approximately 57% of the river is impounded by dams (USACOE, 1990), it is likely that the dam impoundment and operations that modify flows in the mainstem Penobscot may also modify water temperatures that could affect survival of sea-run fish, including endangered Atlantic salmon.

Existing Information

The controlled releases designed to "dampen the variability and occasional extremes of seasonal precipitation" in the West Branch and mainstem Penobscot River (GLHA 2021) directly affect the physical and biological features of the Migration Primary Constituent Elements of Atlantic salmon critical habitat in the mainstem Penobscot (74 FR29300), and thus impact survival of Atlantic salmon and other diadromous fish. The geography, hydrology, and location of the West Branch may contain freshwater habitats that have greater propensity for climate resilience relative to the rest of the state of Maine and to areas that maintain remnant populations of Atlantic salmon. Because of the dams on the West Branch, these climate-resilient habitats are no longer available to Atlantic salmon and other diadromous fish. In summary, temperatures in the State of Maine are increasing as a result of climate change. The average annual air temperature has increased 3.2 degrees Fahrenheit (°F) in the last 124 years; Maine has experienced the six warmest years on record since 1998; and the Northeast is warming faster than any other region in the contiguous U.S. (Karmalkar & Bradley 2017). Along with a warming climate, Maine has seen changes in precipitation patterns as well. The average annual precipitation has increased 15% (5.8 inches) since 1895 with the fastest rate of increase happening since 1960 (more the twice the rate of the long term average); average annual snowfall for Maine has decreased 20% (2.3 inches) over the same time period; most of the increases in precipitation are associated with increased intensity and duration of fall storm events; and despite the increases in annual precipitation, drought events in Maine have become more severe both in duration and magnitude

across the entire state (Fernandez et al. 2020). We contend that the flow modifications at the Penobscot Mills and Ripogenus dams in the West Branch may further exacerbate the effects of climate change (including river flows and temperature) if future climate scenarios are not accounted for in project operations.

Scenario planning is a tool that is used to inform decision-making when there are a range of plausible but uncertain future scenarios, such as climate change (Star et al. 2016). Scenario planning uses a structured process to identify a range of actions that can be taken under different plausible future scenarios. For example, if a future scenario plays out that Maine's climate is significantly warmer and wetter over the next 40 years, then the licensee could have already identified the appropriate mitigation measures, and put in place the necessary tools to adapt to a warmer and wetter environment.

Scenario planning will also allow the licensee to plan seasonally. The Gulf of Maine Council in partnership with the National Weather Service produces quarterly seasonal climate forecasts that provide the most likely climate outlook for the Northeast, including Maine (*https://gulfofmaine.org/public/climate-network/climate-outlook/*). The scenario planning will inform GLHA on appropriate short-term mitigating measures that are necessary to protect aquatic ecosystems in the West Branch and mainstem Penobscot in advance of seasonal climate scenarios playing out.

Nexus between project operations and effects

The controlled releases designed to dampen the variability and occasional extremes of seasonal precipitation (GLHA 2021) directly affect Atlantic salmon critical habitats in the mainstem Penobscot and may directly impact survival of Atlantic salmon and other diadromous fish. The operations of the Penobscot Mills Projects and Ripogenus Dam reduce the magnitude and frequency of flow variability throughout the Penobscot (GLHA 2021). Changes in streamflow, including dam impoundments and flow management through dams, significantly affect water temperatures due to changes in thermal capacity with water temperature being inversely related to discharge (Webb et al. 2003). The combined effect of a warming climate along with altered stream flows can negatively affect the reproductive success of salmonids (e.g. Mantua *et al*. 2010). An analysis of how these dams and their operations may exacerbate potential future climate conditions and identification of mitigating measures that can be taken to offset these impacts, in conjunction with the IHA and Temperature studies that we have requested, is necessary to inform potential license requirements.

Study Area and Study Sites

The study area includes: (1) the impoundments created by Ripogenus (2) the West Branch of the Penobscot River from Ripogenus Dam to the Medway Dam, including all the impoundments created by the Penobscot Mills Project (3) the West Branch of the Penobscot River downstream to its' confluence with the mainstem Penobscot River, and (4) the mainstem Penobscot downstream to the Penobscot Bay estuary.

Analysis

Specific information that needs to be addressed through this study are:

- Identify a minimum of four plausible future climate scenarios considering RCP 4.5 and 8.5 projections for temperature and any future projections for precipitation. Consider likely scenarios such as increases in rainfall, increases in water temperature, decreases in snowpack, and increases in frequency and duration of drought events.
- For each scenario, model the seasonal anticipated future effects of impoundments and flow modifications on river temperatures and flow in the West Branch and mainstem compared to an unimpaired river.
- Identify a range of operational modifications, including flow management, variable depth deep water turbine intakes, and impoundment management, that would be necessary to mitigate the effects of each scenario necessary to afford protections to diadromous fish in the mainstem Penobscot, including endangered Atlantic salmon and their ecosystems.
- Assess how impoundment operations including associated rule curves will be affected by projected future flows in the West Branch of the Penobscot River.
- Assess how access to impoundment tributaries for fish and other aquatic life will be affected by future flows in the West Branch of the Penobscot River.
- Assess how water quality including temperature and dissolved oxygen levels throughout the project area will be affected by future flows in the West Branch of the Penobscot River and designated critical habitat for Atlantic salmon in the mainstem of the Penobscot River below Medway Dam.

Study Plan Criteria

1. The goals of the study are to evaluate how operation of the Ripogenus and Penobscot Mills Projects will affect future stream flows and temperatures in the West Branch of the Penobscot River and mainstem Penobscot River.
2. NMFS is a federal resource agency with a mandate to protect and conserve fisheries resources and associated habitat. Resource management goals and plans are codified in our regulations and governing statutes. We rely on the best available data to support conservation recommendations and management decisions. This study is an appropriate request for the pre-application period.
3. The requestor, NMFS, is a federal resource agency.
4. Currently, there is no information on the effects of operating the Penobscot Mills and Ripogenus Projects on future stream flows and temperatures in the West Branch of the Penobscot River or mainstem Penobscot River. This information is necessary for us to inform potential license requirements to minimize the effects of operating the projects on changing stream flows and temperatures to ensure appropriate operational measures and procedures are in place to afford necessary protections of sea-run fish and their ecosystems.

5. Changes in streamflow, including dam impoundments and flow management through dams, significantly affect water temperatures due to changes in thermal capacity with water temperature being inversely related to discharge (Webb et al. 2003). An analysis of how these dams and their operations may exacerbate potential future climate conditions and identification of mitigating measures that can be taken to offset these impacts, in conjunction with the IHA and Temperature studies that we have requested, is necessary to inform potential license requirements.

6. Downscaled temperature and precipitation data are now routinely analyzed to assess future risks, and can provide a range of future likely scenarios. The use of scenario planning in a risk assessment framework has become the generally accepted practice in the scientific and water management communities for developing actions and strategies to address plausible future climate scenarios. This study request will describe the current practices for the use of climate projections in a risk management framework, in use and mandated by other federal and non-federal water management, resource, and infrastructure planning processes.

   Project operations directly affect the habitat in the West Branch of the Penobscot River and the mainstem Penobscot River. The storage of water in the large reservoirs created by the Ripogenus, North Twin, and Millinocket Dams entirely changes the hydrologic conditions in the river downstream of the project. Impoundments and flow modifications change the thermal exchange rate and thermal capacity of rivers as well as dissolved oxygen levels necessary to support aquatic life. Water temperature affects the migration, movement, spawning and rearing of diadromous fish. Endangered Atlantic salmon are particularly sensitive to relatively small changes in temperature as they have a very narrow range of temperature tolerances. The results of this study will be used to determine the necessity and scope of potential protection, mitigation, and enhancement measures, as well as provide sufficient information that can be used to evaluate the effects of the project on Atlantic salmon and their critical habitat.

7. This study would require a desktop analysis. The preliminary estimated cost for the study, broken down by major tasks, is as follows:

| | |
|---|---|
| Research and Data Compilation | $25,000 |
| Analysis | $35,000 |
| Reporting | $25,000 |
| Total ……. | $85,000 |

For projecting likely changes in climate and their future effects on GLHA's projects and the surrounding natural resources, refer to Star *et al.* (2016).

Comments on Scoping Document 1, Ripogenus Project (FERC 2572-133) and Study Requests

In the late 1980's and early 1990's, when the Ripogenus Project was under consideration for re-licensing, I was the Maine Department of Inland Fisheries and Wildlife Regional Fishery Biologist responsible for fishery management in Chesuncook Lake and in the West Branch of the Penobscot River below Ripogenus Dam. In that capacity I was intimately involved in the re-licensing studies and recommendations responsible for some of the conditons included in the current license issued for the Ripogenus Project. Now that this license is up for renewal again, I have the following comments and recommendations.

The so-called Holbrook Side Channel (Article 406 in the current license) was designed to provide habitat with appropriate flows to increase production of young, wild landlocked salmon for the West Branch population. I recommend studies to determine if current flows throughout the year are adequate to meet the salmon parr production objectives established for this side channel. In renewing the license, it is essential to include a condition prescribing that flows in this side channel will remain adequate for salmon parr production at all flows in the West Branch downstream of Ripogenus Dam. I also recommend a study to determine the suitability for rearing salmon parr in the side channel located on the south side of the West Branch just downstream from Little Ambajackmockamus Falls.

Flows in the Upper Gorge between Ripogenus Dam and McKay Station have not met the objectives for this section of river for the past 25 years! Article 401 of the current license requires a July 1 - September 30 discharge of 100 cfs into the Upper Gorge to provide a cool flow that would attract adult salmon and increase fishing opportunity in the gorge during this period. The recommendation for this flow and its timing was based on observations in years prior to the 1990's, when minimum flows discharged to the West Branch with McKay Station shut down were provided through a deep gate in Ripogenus Dam – hence the cool water. Unfortunately, for the past 25 years the 3-month discharge has been through a small sluice gate that provides warm, surface water to the Upper Gorge, defeating the purpose of Article 401 – 25 years of lost mitigation/enhancement. I recommend 1) studies to determine an appropriate annual minimum flow for the Upper Gorge, and 2) that a new license contain a condition requiring that the 1 July 1 – September 30 flow in the Upper Gorge be provided through a deep gate in Ripogenus Dam, or through an alternative to a deep gate that will provide at least 100 cfs from deep water, not surface water, in Ripogenus Lake.

Thank you for the opportunity to comment.

Sarah Sindo, Millinocket, ME.

My name is Sarah Sindo, and I was born and raised in Millinocket. From May to October, I reside and work at mile 28.5 on the Golden Road at Chewonki Big Eddy Campground. From November to April I am a resident of Kingfield, ME.

I am wrapping up my seventh season here. The campground is mainly known as a fly fishing destination as the West Branch is a world renowned fishery. The native landlocked salmon and brook trout in the river attracts folks from all over the country. There are fishermen that have been coming here to fish these waters for 30+ years, and have told me first hand how much it has changed over the years.

I am writing today with two concerns.

First is my concern with the water levels as they stand today. Ripogenus Impoundment is down 28 feet; it's the lowest people have ever seen it. There are not many people who have eyes on the West Branch 24/7 like I do. I see firsthand how this river is managed. There were a handful of 90 degree and humid days this summer that the river flow was between 3,000-3,400 cfs. There was even one evening from 5-9pm it got bumped from 3,000 to 3,400 for a 4 hour window. The average flow this summer was 1,800-2,200 cfs. So to see 1,000+ cfs increase was a large jump in flow. Considering the drought and extremely low level of Ripogenus Lake, running that high of a flow out of McKay Station was a grave error in water management.

Secondly, I have been witness to at least 1-2 low water excursion events each of the seven seasons I have been here. An outage will occur at McKay Station resulting in a downriver flow of 300-400 cfs, which comes from Ripogenus Dam. The river will stay at this level for 2-4 hours before McKay Station is restored. Not all, but some of these low water excursions, I have witnessed crayfish and other invertebrates in the now dewatered sections of the river, mostly along the shoreline.

I would like to see impact studies done on the river fluctuations and the potential impact it brings to the invertebrates and fishery.

I hope you will consider my concerns, along with the others, before you move forward with the re-licensing. If this river continues to be managed as it has, it will be forever changed in a negative way and its impacts would be widespread.

Thank you,

Sarah Sindo

Brendan Alterio, Pownal, ME.
When the lake is drawn down like present it diminishes the view of Mt. Katahdin. Totally ruins the aesthetics the we have all come to enjoy.

Chad t Mclaughlin, East Millinocket, ME.
As a family friend of a Lease holder I would respectfully request a flow study of Rip Dam off of Chesuncook lake.  Over the last couple years I have noticed a decline in the fishing, snowmobiling, and boating due to the major changes in the lake levels.  I have been coming up here for years fishing and sledding and it has been majorly impacted due to the level changes.  I believe there is no reason for the water levels to be this low.  All the other lakes in the region are close to full capacity for this time of year.  Can you explain why this is happening to this lake?  Is this being done for the rafters, fishing of the river? What about all the people up stream of the dam? Have they not been taken into consideration? Do you realize that this is the 3rd largest lake in the state of Maine with NO development? This is a gem in the shadows of Mount Katahdin and I don't want to see it go to the waste side.  Please take all of this into consideration and fix this major problem.  Thanks

Douglas R Binder, Medway, ME.
For 22 years, I have been coming to my mother and step-father's camp at Chesuncook Lake. I am not a year round resident, but I spent a considerable amount of time there, through all seasons. I am concerned about the water levels during late summer and fall months at Chesuncook Lake chain, to include Ripogenus Lake and Caribou Lake. Every year, I have to pull my boat from the lake, as the water levels get so low in late summer, it is impossible to know the hazards and obstructions that could result in personal injury to myself and my passengers, and also damage to my boat. I have also noticed the consistency of the fishing has also suffered, and it has declined over the past 20 years. It is pretty obscene at the amount of fluctuation of the water levels, especially since other lakes in the same water system, remain mostly full all year. What is this doing to species of fresh water clams and muscles, that live in the shallows that end up being above the water level half the year? How can they survive? Beyond the personal impact on recreational use of the lake, the ecological impact of such massive fluctuation of water levels, of 20 feet or more, every year is devastating to wildlife populations of water base life.

E Drew Fayle, Glenburn, ME.
As a son of a lease holder on Chesuncook Lake, I would like formally request a Flow Study of the lake. The Water level of the Chesuncook and Rip have been excessively level changes which make navigating the lake very difficult. I would also like to make notice on the wasteland the lake looks like due to the water level being drawn down. I would also like to have this completed due safety concern when snowmobiling on the lake due to exposed rocks and pressure ridges. Again I want to Request a Flow Study on the Chesuncook Lake and other bodies of water.

Gregory Friel, Millinocket, ME.
I would like to comment on the Millinocket Stream water flow levels. I am a local high school outdoor education instructor, registered Maine guide, life long Millinocket resident and parent. I have used Millinocket Stream with my outdoor education class, guiding, kayaking and fishing with my family for 35 plus years. I have some strong concerns about the low water flows over the past 4-5 years.The stream has gone from an absolute gem for outdoor recreation, canoeing, kayaking, fishing and guiding to a stream so shallow that it is no longer able to allow passage of a canoe or kayak which only draw several inches of water. This stream has great potential to be a recreational hub but it needs water, the flow levels of 65-75 cfs seems to be the new normal but is not the historical flow. I would like to see the minimum flows increase to a flow that allows for canoe passage without having to get out and drag the vessel, 150-200 cfs isn't much but would probably be acceptable. The water is constantly pumped out of Millinocket Lake across to the Pemadumcook Chain of lakes which has resulted into pure neglect of Millinocket Stream as a resource for recreational opportunities. With the number of streams flowing into Millinocket lake it should be manageable to meet at least a flow of 200 cfs. I know Brookfield likes to keep the camp owners on Millinocket lake happy with a full lake and I believe this can still happen with Millinocket Stream receiving a little more water and the Pemadumcook chain receiving a little less. No I'm not a camp owner but think recreational users need the same considerations that the camp owners are getting from Brookfield power. The water in Maine belongs to the all of the people in the state of Maine not just the camp owners and certainly not the ones in control of the dams. Thanks you for any considerations given to Millinocket Stream.

**RE: Ripogenus Hydroelectric Project (FERC No. 2572)**
**Comments on PAD and SD1 Documents**

Dear Secretary Bose:

I am writing as a waterfront property owner within the above referenced re-licensing project area. My seasonal camp is on Caribou Lake (Lot CA8), within the Ripogenus impoundment created by Ripogenus Dam.

I have reviewed the Pre-Application Documents (PAD) filed by Brookfield dated June 11, 2021, as well as Scoping Document 1 (SD1) and offer several comments pertaining only to FERC No. 2572.

My concerns relate to the significant, persistent lake water level drawdowns that have occurred over the last 5 years of owning my camp. The normal full pond elevation of 941.59 feet has only been periodically reached over the last 5 years. Lake drawdown to levels over 20 feet occurs during the summer recreational boating season (ice-out to Labor Day). Basically, my recreational access has been eliminated during the summer months due to excessive lake drawdown. Dragging a 300 pound boat 200 – 300 feet over boulders, sharp slate and fractured ledge is not feasible. Although not stated in these reports, it is worth repeating that permanent docks attached to the lake bottom are not allowed in the Ripogenus impoundment, and I have no problem with that.

Photo 1 on the next page is from Labor Day, 2021 when the lake drawdown was approximately 21 feet. The lake level had been this low for several weeks. The distance from the shoreline to the water's edge was 288 feet (measured with 100 foot surveyors tape). In these conditions, my access is limited to a canoe and kayak.

Recreational access and lake level stability in the Ripogenus impoundment during the summer months are two issues I wish to see considered in the NEPA process.

**Photo 1. View on Labor Day, September 6, 2021. Distance from edge of grass to water is 288 feet. Upland vegetation is spreading in the first 100 feet. Rock in foreground is approximate 942 pool elevation.**

The second photo below shows the bouldery, rocky terrain exposed for much of the summers of 2020 and 2021. Launching and removing a motorized boat is difficult at best.

**Photo 2. View towards Caribou Lake from Lot CA8 on September 6, 2021.**

Since launching a boat is not possible from the camp, I have checked out the one public access point. The Ripogenus Project existing recreation facility on Caribou Lake consists of one boat put-in (Caribou Lake Put-In). I checked the put-in 3 times in summer 2021 and 3 times in summer 2020 and the water level was below the put-in – I would not use my trailer on it.

**Comments on PAD Document**

The PAD contains the following statement in a couple places:

> *During normal operation and normal inflow years, the Ripogenus impoundment elevation is held relatively stable at 941.6 feet during the summer months…*

This has NOT been the case since 2015 when I purchased my camp. I am told that this may have been true back when Great Northern operated the dam, but has not been the case since Brookfield began operations.

**Comments on SD1 Document**

GLHA proposes to continue their current operations under the new license with no changes in operation. The proposed operations for the new license address downstream minimum flow requirements only (*Section 3.1.4*). Upstream impacts and/or mitigation relative to lake water levels are not mentioned.

No mention of lake level requirements for the Ripogenus impoundment is made. The SD1 document relies on the same incorrect assumption as the PAD document, namely, that: "… *the Ripogenus impoundment elevation is held relatively stable at 941.6 feet during the summer months".*

Likewise, *Sections 4.1.2 and 4.1.5* largely focus on downstream issues to be addressed in the NEPA document. No specific mention of recreational access or the impact of significant summer lake level drawdowns in the Ripogenus impoundment is made.

At a minimum, the NEPA process should include a presentation and review of existing historical discharge and lake level data for Ripogenus Dam. The lake level fluctuations should be analyzed and correlated with precipitation and discharge. It appears that the lake level fluctuations and drawdowns correlate most directly with Rip dam releases/discharges. To say that, 'well, it has been a drought year' is not adequate.

**Proposed Mitigation Measures for New License**

According to the SD1 there are 3 options for the new license: No Action, Proposed Action, and Alternative to the Proposed Action. In my opinion, the No Action and Proposed Action options are not acceptable. An alternative to the proposed action, that incorporates seasonable lake level requirements for the Ripogenus impoundment, is needed to provide recreational access during the boating season (Ice-out to Labor Day).

The lake level requirements for nearby North Twin Lake provide an example of a workable solution for the Ripogenus impoundment, which could be worded as follows:

*From ice-out to Labor Day, the Ripogenus impoundment is refilled and is maintained at a relatively stable target elevation of 940 feet (within 1.6 feet from normal full pond elevation) plus or minus 0.5 feet.*

Thank you for considering these comments. Hopefully, recreational issues/lake level requirements for the Ripogenus impoundment will be considered in the re-licensing process.

**Instream-Flow Management for the West Branch of the Penobscot River, Maine: Hydropower vs. Recreational-Use Conflicts**

ROBERT L. VADAS, JR.[1]

*Department of Fish and Wildlife Conservation*
*Virginia Polytechnic Institute and State University*
*Blacksburg, VA 24061-0321*

*Abstract.*-Above natural migration barriers for sea-run fish, landlocked Atlantic salmon formerly provided an impressive fishery in the West Branch of the Penobscot River, ME. This once-stocked run has declined in distribution and abundance recent decades, due partly to reduced rainbow smelt runs (prey). This dammed river has also been managed for lucrative whitewater rafting/tubing companies more recently, via changes to the instream-flow regime that apparently have reduced salmon productivity. Moreover, changes in fishing regulations and elimination of former fishing bonanzas during holidays (when river flow for hydropower production was reduced) have impacted angling success for this wilderness river. Although Trout Unlimited (TU-National) once advocated for instream-flow changes that were better for salmonids here, based on past PHABSIM (Physical Habitat Simulation) studies, their “spoiler” role really didn’t benefit this salmon fishery (despite a subsequent ‘Trout’ magazine article that overemphasized its angling value). Unfortunately, a “cookbook” management approach has not worked here.

[1]*Present address:*
2909 Boulevard Rd. SE, Olympia, WA 98501-3971, USA, Phone: (360) 705-2231, E-mail: bobesan@comcast.net.

I submit the present information as an instream-flow scientist, including work on both Atlantic and Pacific salmonids (Vadas 2000; Vadas and Vadas 2005; Vadas et al. 2008, 2016) and ecohydrologic considerations for other freshwater and estuarine vertebrates (Vadas 1994a, 2003; Khatun et al. 2020) and riparian trees (Vadas and Weigmann 1993; Vadas and Sanger 1997; Hughes and Vadas 2021). I also have much angling experience in the West Branch of the Penobscot River, ME.

Over a decade ago, my father and I published a short note in 'Trout' (Vadas and Vadas 2005), critiquing a previous tribute article in that magazine (McGurren 2002) that over-touted the landlocked (past-stocked) fishery for Atlantic salmon (*Salmon salar*) in the West Branch. Although this wilderness river above natural fish barriers is still clean/cold, angling success has declined in recent decades (Table 1; see below). Our experience has collectively included (a) regular angling and camping/cottage outings on the West Branch since the late 1960s and (b) my consulting services on instream-flow issues there two decades ago for TU-National (Appendix 1). Since 2005, my family and friends have continued to fish this river, with no major, widespread improvement in fishing success since the heydays of the 1960s to 1980s. Indeed, the only mainstem sections with any recent summer/fall angling success have been below McKay Station powerhouse and well-downstream near Sourdahunk Stream (B. Grandchamp and E. Spear, pers. comm. 2020-2021), whereas other, previous "hotspots" up- and downstream have not been productive in the new millennium (RLV, pers. obs.). I do agree with McGurren (2015), however, that the West Branch provides better salmon fishing than the other three headwater-river forks.

Although McGurren (2002) indicated that some 10 lb (4.5 kg) salmon may reside there since the 1920s planting of this stock, we haven't heard of such large fish being caught (Table 1), based on discussions with the local game warden and fish biologist (Vadas and Vadas 2005). The largest salmon angled during the West Branch heyday (prior to the mid-1990s) were 6-7 lb (~3 kg) fish collectively taken near the McKay Station and downstream at Sourdahunk Falls (a fish-migration barrier). Larger fish caught there, however, have usually been much smaller than this, particularly more recently since stocking ended in 1978 (op. cit.). Such fish sizes reflect their landlocked life cycle, as *S. salar* adults (total length = 47-90 cm = 18.5-35") do not reach the maximum size of anadromous salmon (140 cm = 55") in the Atlantic Northeast (Lee et al. 1980). Rather, their body sizes are more similar to Atlantic salmon grilse, which spend only one year at sea in eastern Canada (Table 1). Notably, landlocked salmon of 18-21" (46-53 cm) TL should be 2.5-3.5 lbs (1.1-1.6 kg) in weight (Behnke 1988). Table 1 shows notable size differences of larger

salmon caught in recent decades here, as compared to sea-run Atlantic salmon from one of the best fishing rivers in eastern Canada, i.e., the Main Southwest Miramichi River near Doaktown, NB (Belding 1934; Elson 1957; Vadas 2002; FLAO 2021). In more recent decades, the strong rainbow smelt (*Osmerus mordax*) runs of the West Branch – which once provided salmon food when Chesuncook Lake (Ripogenus Dam) outflows were high (McGurren 2002) – have diminished along with the salmon runs and adult growth (body sizes) (Vadas and Vadas 2005; E. Spear, pers. comm. 2021; cf. Behnke 1988). A similar salmon-smelt problem has occurred farther upstream in the most-remote segment of this river, i.e., between Ripogenus and Seboomook dams that formerly provided good salmon fishing (Vadas and Vadas 2005). Of interest for future salmon-abundance projection is the return of dirt-road conditions below Ripogenus Dam, given the conversion of pulp-and-paper mill to paper-recycling operations in East Millinocket, as logging (and thus truck transport) decreased (RLV, pers. obs.). Despite declining fisheries success in recent decades, it's still possible to catch over one salmon in 20 h in the best habitats (pers. obs.), which is considered to be a normal catch cate for landlocked stocks (Behnke 1988). Fortunately, forested-conservation easements are important along both riverine forks of the upper Penobscot River drainage (BGNP 1992), within sight of Mt. Katahdin (northern end of the Appalachians) as scenic destinations.

As logging activities declined, the top business operation in the West Branch became whitewater rafting and (more recently also) tubing (Vadas and Vadas 2005, pers. obs.; cf. BGNP 1992). Although there is better cooperation between these companies and anglers since the successful opposition to the downstream-proposed "Big A" dam in 1984 (Klausmeyer 2002; McGurren 2002), there were serious conflicts that have fortunately decreased more recently, except for naïve tubing enthusiasts (Vadas and Vadas 2005, pers. obs.). The remaining drawback of whitewater rafting, however, is that low flow/electrical-production weekends no longer occur during summer holidays, which once provided the best fishing action (op. cit.). Indeed, lower flows are best for fishing there, with 1300-2000 cfs (37-57 $m^3/s$) being optimal for wading anglers and up to 3000 cfs (85 $m^3/s$) for boat anglers (McGurren 2002). This concords with literature data, for which whitewater rafting has higher instream-flow requirements than do other recreational activities like angling, swimming, and aesthetics (Fritschen et al. 1984; Beecher 1990), thus requiring compromises even without consideration of off-stream uses (Vadas and Weigmann 1993; Pacheco and Beecher 2010) that are minimal here. Unfortunately, instream-flow management has favored whitewater rafters over anglers in the West Branch (Vadas and Vadas 2005), which TU-National unwittingly facilitated by advocating for

relatively high flows throughout the landlocked salmon's range (Appendix 1). Periodic (e.g., weekend) cessation of hydropeaking operations can benefit lotic ecosystems (Poff and Schmidt 2016), albeit lower flows would now be better on weekdays (especially early in the week) when less whitewater rafters grace the West Branch (Vadas and Vadas 2005, pers. obs.).

Nevertheless, overly low flow flows from hydropower-caused flow fluctuations in the West Branch dewater productive side channels like that adjacent to Holbrook Pool (E. Spear, pers. comm. 2021), so better flow stability on daily and interannual time scales is important for long-term salmonid success (Vadas 2000, 2003; Vadas et al. 2008, 2016). Seasonally, there should be higher flows during the reproductive than rearing (growing) seasons for salmonids and other fishes (Vadas and Weigmann 1993; Vadas 2000, 2003; Annear et al. 2004). Notably, fishes need more flow stability than riparian trees (Vadas and Weigmann 1993; Vadas and Sanger 1993) and especially whitewater rafting, which perturbs the West Branch's hydrology away from normative (semi-natural) conditions that native biota are adapted to. Indeed, Trotsky and Gregory (1974) documented adverse effects of daily-fluctuating flows upon macroinvertebrate numbers, biomass, and species richness in another Maine river. Such hydrologic impacts, as well as thermal changes from dam operations and riparian deforestation, often impact aquatic-insect life histories to reduce important salmonid prey like immature/legged taxa (Barnes and Minshall 1983; Resh and Rosenberg 1984; Ford et al. 1995; Vadas 1997, 1998).

Another change in instream-flow management resulting from TU-National negotiations was putting more water into the bypass section directly below Ripogenus Dam (above the McKay Station powerhouse). Although this potentially improved the flow regime for salmon, the limnophilic, lower-flow needing brook trout (*Salvelinus fontinalis*) (Rupp 1954; Gibson 1978; Fausch 1988; Gibson and Cutting 1993; Ford et al. 1995; Bélanger and Rodríguez 2001, 2002; McGurren 2002; Deschênes and Rodríguez 2007) that formerly provided good fishing have likely declined given suboptimal flows (Vadas and Vadas 2005). And the formerly good salmon fishing there is compromised by warmer tailwaters, given changes in dam operations away from cold-hypoliminial releases from Chesuncook Lake (E. Spear, pers. comm. 2021). Hence, the only remaining good fishing for West Branch brook trout is (a) in groundwater-fed tributaries and (b) where they enter the mainstem (Vadas and Vadas 2005), similar to the Main Southwest Miramichi River where these char are also less mainstem-oriented than sea-run Atlantic salmon (Vadas 2002; FLAO 2021; cf. Rupp 1954; Gibson and Cutting 1993; Carpenter 2004). That is, the loss of spatial diversity in instream-flow regimes that TU-National negotiated (against my

caveats) has apparently reduced brook trout angling opportunities for this native West Branch species. Moreover, flow augmentation for whitewater rafters farther downstream (below McKay Station) has further reduced brook trout fishing success in the mainstem (Vadas and Vadas 2005). Other fish regularly caught there (especially near shore where it's slower) are fallfish minnows (*Semotilus corporalis*), which are too bony to be regular dinner fare (op. cit., pers. obs.).

In sum, the West Branch is no longer the great salmon fishery that it once was, likely given the combination of (a) dam-hydrologic changes for whitewater rafting, (b) more-conservative fishing regulations, and (c) cessation of stocking in more-recent decades (Table 1; Vadas and Vadas 2005). McGurren's (2002) overestimation of its salmon fishery may reflect his fishing-guide profession, proclivity towards angling farther downstream in the mainstem Penobscot River (McGurren 2015), and/or TU's interest in touting its role in the FERC negotiations, despite limited benefits for West Branch anglers unlike whitewater-rafting companies. Hence, a more-flexible approach to negotiations could allow better anglers success, for more-diversified recreational opportunities here. Indeed, the PHABSIM models used in the West Branch negotiations are meant to be used incrementally, to develop reasonable compromises for multiple-user benefits (Vadas and Weigmann 1993; Annear et al. 2004; Pacheco and Beecher 2010). This could help return the West Branch to the healthy ecosystem that it was when I was growing up. Clearly, further biophysical studies are needed for this effort, especially given increasing climate-change impacts on fish and wildlife in the USA (WMI and TRCP 2009; Hughes and Vadas 2021; Hughes et al. 2021).

**Acknowledgments**

I thank D.J. Orth (Virginia Tech) for offering me past consulting work for West Branch dams, TU-National for access to FERC-relicensing documents, and C.F. Gauvin (its then-CEO) for review of my 1993 consulting report that the present paper draws from. Supreme anglers E. Spear and R.L. Vadas, Sr. collectively contributed information and literature on fishery, hydropower, and logging issues, whereas Virginia Tech and subsequent employers have provided resources for writing this paper (although not necessarily endorsing it).

Table 1. Larger (but not maximum-sized) Atlantic salmon caught by family and friends in the Atlantic Northeast in recent vs. past decades, including for the West Branch of the Penobscot River (landlocked stock via non-winter fly-fishing and other angling methods [Vadas and Vadas 2005, pers. obs.]) and Main Southwest Miramichi River, NB (anadromous stock via vernal fly-fishing [Vadas 2002, pers. obs.]). Mass units are lb and (in parentheses) kg, with the help of Behnke's 1988) total-length (TL) vs. weight conversion factor (see the text). Time periods include 'old' (late 1960s to early 1970s), 'medium-old' (mid-1970s to early 1990s), and 'more-recent' (since the mid-1990s). During the medium-old time period, total length for harvest (a) increased from a minimum of 14" (~36 cm) to 18" (~46 cm) on the Penobscot and (b) was a constant maximum of 63 cm (i.e., ~41" for 'grilse') on the Miramichi (op. cit.). Penobscot bait-fishing was also greatly curtailed during this period (RLV, pers. obs.). Lack of fishing data is indicated by --.

| River | Old | Medium-old | More-recent |
|---|---|---|---|
| Penobscot | 4-5 (~2) | 3-4 (~1.5) | 1-2 (~0.75)[a] |
| Miramichi | -- | -- | $\leq$ 16 (~7.3)[b] |

[a]We have caught salmon up to 20-22" (51-56 cm) TL in recent decades here, but fish are typically under 18" (46 cm) long (RlV, pers. obs.; E. Spear, pers. comm. 2021).

[b]We have caught salmon up to 41" (104 cm) TL, albeit salmon up to at least 43" long and 30-40 lb (~14-18 kg) have been angled here (Vadas 2002, pers. obs.; FLAO 2021). Harvestable grilse, which spend only one year at sea, typically weigh 3-6 lb (~1.4-2.7 kg) in New Brunswick (Elson 1957; FLAO 2021).

Appendix 1. Scientific concerns about the advocacy of Trout Unlimited (TU-National) for fishery success and instream-flow management in the West Branch of the Penobscot River, ME.

---

*"Eternal vigilance is the price of liberty." Thomas Jefferson*

Our response article (Vadas and Vadas 2005) to Pat McGurren (2002) – a fishing guide in the Penobscot River basin and member of TU's Georges River Chapter (McGurren 2015) – was faciliated by TU's Joe McGurren, who (unrelated to Pat) better advocated for our article than did the past editor of 'Trout'. Unfortunately, we were able to publish only a summary note, the full article appearing in the supposedly permanent 'Trout Magazine' blog that disappeared long ago from TU-National's website. We subsequently (in 2008) published the full article in the Olympia Chapter of TU's newsletter. I wonder how many other 'Trout' articles about salmon rivers, including those in the Pacific Northwest, have exaggerated the angling benefits? This emphasizes the importance of constructive peer review by multiple experts – including local sportsmen, game wardens, and biologists – for outdoors magazines like 'Trout', especially if that information is to have any scientific and management value (cf. Alessi and Miller 2012).

During my past consulting work for TU-National in 1993 (as a graduate student), I helped secure more fish-friendly flows for the West Branch. However, TU-National over-touted high flows, possibly to bankrupt the pulp-and-paper mill company (i.e., Great Northern Paper Company [GNPC]) that owned the dams then, rather than to achieve a "win-win" solution during the Federal Energy Regulatory Commission (FERC) relicensing process. This included veiled threats of landlocked Atlantic salmon perhaps getting federally listed, even though Endangered Species Act listing was subsequently reserved only for native, anadromous populations below natural barriers in Maine (Diaz-Soltero 1997; Musick et al. 2000; Klausmeyer 2002; Dudley et al. 2008). For these reasons, TU-National alienated itself from some of its Maine chapters, such that one Sunkaze Chapter member complained to me (years later) while fishing the lower, warmer Penobscot River where sunfishes are abundant (cf. McGurren 2015). The angler initially blamed me, so I explained that despite working as a TU-National consultant, I didn't necessarily agree with its hardline, "spoiler" tactics to join the FERC negotiation only in the "11$^{th}$ hour". More recently, I heard (through past TU leadership for Washington state) that I was branded as "not being a team player" for the West Branch negotiations, given my side discussions with the "other team" (GNPC) to find common ground (e.g., the

likely importance of rainbow smelt relative to cypriniform fishes in West Branch salmon diets). Hence, I wasn't allowed to speak to local-chapter members during an associated TU banquet in Maine during 1993. Nor did I secure further instream-flow or other paid work with TU-National (Vadas 2015). Later as a company consultant in Alberta, I saw and heard about unfair pressures from the industrial side, which often circumvented scientific concerns because "this is an important client" (op. cit.). Hence, both environmental and business interests often try to sway their consultants to say what they want to hear (op. cit.; Hughes et al. 2021).

As a result, I switched to government habitat-biology work, where the bottom line is not pleasing chief-executive officers (CEOs) or stakeholders. Scientific bias, however, does cloud agency negotiations for salmon (Lichatowich 1999; Montgomery 2003; Lackey 2015), other fresh- and saltwater fishes (Doubleday et al. 1997; Healey 1997; Hutchings et al. 1997a,b; Gunderson 2011; Vadas 2019) and wildlife (Aron et al. 2002; Orians et al. 2003), and terrestrial biota (Glick 2002; Karr 2006; Laskawy 2010; Alessi and Miller 2012; MICRA 2015; Zaffos 2015; Hughes et al. 2021). The same is true of academic research via "ego" battles (Vadas 1994a) and the dealings of the American Fisheries Society (AFS) and other environmental organizations that don't want to offend their financial supporters (Grossman 2015; Vadas 2015, 2019). Despite AFS' (2004) scientific support of dam breaching to recover North America fisheries, AFS-National subsequently voted down such advocacy for the lower Snake River (LSR), where four run-of-the-river, hydropower dams have (as predicted [Needham 1949]) greatly reduced salmon runs in this large Columbia River tributary, despite formerly important salmon runs and relatively undeveloped headwaters (Huntington et al. 1996; Lichatowich 1999; Nemeth and Kiefer 1999; Fraser and Kitzhaber 2002; WDAFS 2009). This likely reflects past agency biases for reservoir over stream fisheries (AFS 2015), although the Western Division of AFS (through its new Resource Policy & Environmental Concerns Committee) is reinvigorating its promotion of LSR-dam breaching for salmon and Southern Resident orca (killer) whale benefits (Vadas 2019, unpubl. MS). To adapt Thomas Jefferson's quote, "Eternal vigilance is the price of" doing natural-resources science and management.

TROUT UNLIMITED
MAINE COUNCIL

**Via online submission to: http://www/ferc.gov (cross-filed)**

Subject: **Comments of Maine Council of Trout Unlimited on the Notices of Intent and Pre-application Documents for the Ripogenus Project (P-2572) and the Penobscot Mills Project (P-2458)**

Dear Secretary Bose:

On behalf of its six chapters and over 2,000 members, Maine Council of Trout Unlimited (TU) submits these comments on the Notices of Intent (NOI) and Pre-application Documents (PAD) for the Ripogenus Project (P-2572) and the Penobscot Mills Project (P-2458) filed for Great Lakes Hydro America, LLC by Brookfield Renewable ("Brookfield" or "Applicant") dated June 11, 2021. TU submitted preliminary comments on September 16, 2021[1] asking for documents referenced in the PAD and 90 days after their receipt to conduct a meaningful PAD review in light of them. FERC rejected requests from NMFS,[2] USFWS,[3] MDIFW,[4] and MDMR[5] for information, documents and a 90-day delay, as well as a follow-up Scoping Meeting to better deal with stakeholder comments. TU subsequently requested documents be provided prior to the Study Plan Meeting in a second letter containing preliminary PAD comments.[6]

**Background**

Taken together, the Ripogenus and Penobscot Mills relicensings reflect over 108,000 kw of generation capacity making this the largest relicensing effort in the state of Maine in terms of electricity production by a large margin. The waters and surrounding habitat affected by these relicensings are of equal stature. The land-locked salmon fishery below Ripogenus Dam is sustained by naturally spawned fish and nationally known for its quality. With Maine's highest mountain nearby, Ripogenus Gorge below the dam is Maine's most spectacular gorge. The waters of the Penobscot Mills Project are also important in their own right and should play a part in the restoration of currently dewatered sections of the West Branch of the Penobscot River to provide traditional waterways and sustenance fisheries to the Penobscot Indian Nation (PIN) that have been so long promised but not delivered.

[5] Maine Department of Marine Resources letter RE: Extension of Time Request for the Ripogenus (FERC No. 2572-133) and Penobscot Mills (2458-247) Hydroelectric Projects of September 17, 2021.
[6] TU Letter dated October 2, 2021, Subject: Preliminary Comments of Maine Council of Trout Unlimited on the Notices of Intent and Pre-application Documents for the Ripogenus Project (P-2572) and the Penobscot Mills Project (P-2458)

Brookfield's submission places great stock in studies conducted many years ago during the last relicensing.[7] Brookfield Renewable, the entity that is responsible for PAD content, has only been in Maine as a corporate entity for about ten years. Brookfield is asking for the process to rely on prior studies that were NOT conducted by Brookfield - all Brookfield knows about them and the circumstances surrounding them is second or third hand information. The outcomes for the last relicensings of these projects were driven by the fact that then the electricity produced went directly to the mills in Millinocket. Any increase in the generation costs would have a potential effect on the economic viability of the mills, and decisions were made on the balance between the jobs and economics in local communities and the standards in state and federal environmental law. With the mills now closed and the electricity sold to the grid, that balance has fundamentally changed. In addition, environmental conditions and the operations of these projects have changed over the past 30 years. Climate change has been documented to have changed ice out dates and is suspected to have changed precipitation and river flows. Numerous stakeholder comments heard during the course of stakeholder meetings concerned apparent peaking activities associated with the operation of McKay Station. While the Penobscot Mills Project generation facilities are run of river operations, this appears to enable the operator to create a 'rolling peak' since the operator considerable flexibility to manage the water levels in the project's impoundments, and to control released from upstream storage at the Ripogenus Project and from upstream storage reservoirs.

Besides the apparent change in project operations, climate change must be considered. Most of the last five years have been relatively dry ones. Lake levels in the Ripogenus-Chesuncook reservoir appear to be historically low as supported by numerous stakeholder comments to that effect, and this may be due to climate change. Stakeholders continue to report that it has been years since the impoundment has been at any level resembling full pond based on vegetation on the margins. It is an open question whether this reflects a change to project operations, climate change, or both. Rather than rely on anecdotes or assurances, new study data is essential.

With this as a backdrop, it is inappropriate for the Applicant to rely so heavily on summaries of 30-rear-old studies described in past license applications. Doing a word search of the PAD Volume 1, Part 1 on "GNNC 1991a" and "GNNC 1991b", the prior license applications, yields 81 and 74 occurrences respectively. The FERC process exists to review the status of projects every 30 to 50 years because both environmental conditions and the balance between project impacts and benefits are subject to change as is undeniably the case with the Ripogenus and Penobscot Mills projects. Small projects of 10 megawatts or less can be designated as exempt from this process and issued FERC Exemptions**. This is not a FERC-exempt project whose operating conditions continue in perpetuity.** The National Environmental Policy Act (NEPA) requires a "Well Considered" and "Fully Informed" study.[8] If we are to accept past data and past studies, stakeholders should know exactly what we are accepting and not have to rely on summaries provided by the applicant. Only then will resource protection agencies and stakeholders be able to generate appropriate FERC study requests. It must also be noted that most of the referenced studies are older than the 10 years specified for studies by the courts in American Rivers III.[9] The commission appears to be ignoring this; indeed the Commission's response to the Penobscot

[7] Brookfield Notices of Intent and Pre-application Documents for the Ripogenus Project (P-2572) and the Penobscot Mills Project (P-2458) dated June 11, 2021, page 1-11. "*GLHA maintains that a full suite of new studies is not needed, that the vast body of information on which today's certifications and licenses are soundly based and should be relied upon for these relicensings. In addition, consistent with the Commission's criteria for study requests, the scope and extent of any new study be focused on addressing specific data gaps necessary to inform the development of license requirements.*"

[8] Implementation of the National Environmental Policy Act (NEPA) of 1969. Federal Register / Vol. 73, No. 200 / Wednesday, October 15, 2008 / Rules and Regulations 61299.

[9] American Rivers and Alabama Rivers Alliance v. FERC and United States Secretary of the Interior, No. 16-1195 (D.C. Cir. 2018) ("American Rivers III").

Indian Nation (PIN) request for the Commission to explain how its policies have changed as a result of American Rivers III was to refuse to discuss impact of the decision.[10] We hope that the Commission will reconsider the implications of American Rivers III and apply them going forward.

The applicant proposes a minimal and inadequate list of studies.[11] These appear near the end of Volume 1, Part 1. We will comment on these later in this document in the last portion of the Specific Comments section and these comments will form the most important part of this filing. Please bear with us as we provide comments for the record to address the content the Applicant has provided concerning the proposed studies. Emphasis is provided for clarity due to the high number of specific comments.

**General Comments**

1. Language

The Applicant uses language to minimize the impacts of its projects that dewater significant segments of the main stem of the West Branch of the Penobscot River in two areas:

> "bypassed reach" to described the section of the mainstem of the West Branch of the Penobscot River below Ripogenus Dam that is watered by leakage flows for nine months out of the year. "Dewatered section of the West Branch Penobscot River in upper Ripogenus Gorge" is a more accurate and descriptive term that should be used in project documentation going forward.
>
> "Back Channel" is used extensively to describe the main stem channel of the West Branch of the Penobscot River below Stone Dam that is only watered with leakage flows of 2 - 5 cfs during the summer months of most years. This is NOT a back channel. "Dewatered mainstem of the West Branch of the Penobscot below Stone Dam" is a more accurate and descriptive term that should be used going forward.

In the interest of brevity, we will not cite each instance of these.

**Specific Comments**

1. Title page (unnumbered). At bottom of the page (and over 400 subsequent ones) this notation appears: "*Copyright © 2021, Great Lakes Hydro America, LLC. All rights reserved."* The FERC process is a public one that actively seeks comments from the public. While these notations were appropriate to the documents before they were filed to the FERC dockets, once they were posted, the document became part of the public domain. Accordingly, the notation became incorrect the moment the document was filed. Including it can only serve to confuse those unfamiliar with the process, and discourage use of the filing in the media. The notation should NOT be included in future filings for these relicensings.
2. Page 1-5. Paragraph at top of page omits the fact that the construction of McKay Station rerouted the main flow of the West Branch of the Penobscot River through the water tunnel generally dewatering Ripogenus Gorge upstream of the powerhouse except for leakage flows and during high flow periods when the flow capacity of the powerhouse is exceeded.
3. Page 1-10. " *Establishment of 2,300 acres of land surrounding the Back Channel as a Wildlife Management Area and implementation and maintenance of various measures for the*

[10] FERC Letter dated September 28. Reference: Response to Extension of Time and Additional Public Meeting Requests, and Request for Information for the Ripogenus Project No. 2572-133 and the Penobscot Mills Project No. 2458-247, page 2.
[11] PAD page 6-81 and subsequent.

*enhancement of wildlife habitat in the area*." This remediation measure tacitly acknowledged the environmental damage caused by dewatering the main stem of the West Branch of the Penobscot River. While the remediation was better than nothing, it failed to address the direct harms caused by seasonal dewatering including loss of the structure and function of that reach of the main stem of the West Branch of the Penobscot River and denies the PIN with the means of accessing their traditional waterways during the summer.

4. Page 1-11: *"GLHA maintains that a full suite of new studies is not needed, that the vast body of information on which today's certifications and licenses are soundly based and should be relied upon for these relicensings. In addition, consistent with the Commission's criteria for study requests, the scope and extent of any new study be focused on addressing specific data gaps necessary to inform the development of license requirements."* TU strongly disagrees with this. Changes in operations due to changes in ownership, climate change and other changes that have occurred over the last thirty years must be considered.

5. Page 1-11 and12: "*Based on the totality of studies conducted, settlement agreements reached, PM&E measures incorporated, and water quality certifications issued, FERC's 1996 licenses concluded that the Projects are best adapted to serve the public interest. GLHA maintains that nothing has significantly changed that would alter this conclusion. If anything, the fight against climate change as well as socioeconomic challenges to the region only amply the importance of ensuring that these relicensing proceedings do not result in a reduction of the Projects' ability to produce clean, renewable energy."* **While the PM&E measures MAY have reflected the public interest at that time, this is not necessarily the case today.** Much has changed since 1996: changes in the local economy and community; changes in the use of the electricity produced; changes in the way the project is operated; and potential changes in both the other uses of the resources of the West Branch Penobscot River and in its biological communities. FERC licenses are not permanent and need to be renewed for a reason: to accommodate changes with a periodic re-examination of each project.

6. Page 1-12. "*GLHA's overall approach and overarching interest in these relicensings centers on: Maintaining the sound balance between power and non-power values that exists today as achieved through the extensive proceeding that resulted in the Projects' existing licenses;"* The FERC **re**licensing process exists to ensure that the sound balance is periodically re-assessed, and, as appropriate, adjusted.

7. Page 1-12, the paragraph continues: "*Preserving the Projects' renewable energy and capacity provided to the local electrical grid, as well as preserving the economic viability and significant investments made by GLHA over the terms of the Projects' existing licenses; and:* need for power on the grid is declining as other renewable sources such as solar and wind continue to be developed.

8. Page 1-12, The last item in the paragraph: "*Recognizing and leveraging the collective value of the Projects' existing PM&E measures, environmental monitoring activities over the terms of the Projects' licenses, and associated body of existing information as a legitimate basis for decision-making."* While the existing PM&E measures are significant, they need to be revisited as part of the relicensing process. Clear examples: Since the mills closed, the population of the Millinocket area has decreased significantly; the local demographic has changed and so should be their needs relating to use of the resource. Whitewater is a recognized recreational use, and kayaking is now a significant art of that; kayaking has greatly increased over the last thirty years.

9. Page 1-112. The applicant describes the projects as "*carbon-free energy.*" This is simply NOT the fact due to methane gas production by impoundments described in a growing body of scientific literature.[12] **While the carbon profile is much less than fossil fuels, the Applicant's claim of *"carbon-free energy"* is incorrect as stated, and this is repeated elsewhere in the PAD without supporting study data.**

10. Page 1-113. The second paragraph discusses the need for flexibility that hydro provides. Brookfield has constructed two battery storage facilities at the projects[13] to provide additional flexibility. Battery storage is a mature technology that solar and wind generation facilities can also use this same technology to meet peak demands. While the flexibility described is desirable and was formerly a major advantage to hydro technology, mature battery storage technology is a means of replacing that flexibility. It is a good option to peaking projects that can have serious effects, especially on the littoral zones of impoundments. Battery storage gives the operator a more environmentally friendly option. When asked if the two battery storage facilities has constructed for the Ripogenus and Penobscot Mills Projects were going to be used for this purpose, the Applicant's response was "no."

*11.* Page 1-114. "*If the existing flexibility, operational ranges, or peaking capabilities of the Projects as presently licensed were further limited or curtailed, the ISONE would need to rely more heavily on natural gas burning facilities to meet peak power demands now and into the foreseeable future.* **The Applicant describes a lack of flexibility with the projects, and fears of them being "*further limited*." This is simply not the case. The Ripogenus-Chesuncook reservoir can be drawn down as far as the mechanisms of Ripogenus Dam allow (44 feet), the interconnected reservoirs of the Penobscot Mills projects have minimum restrictions on water levels, provision for pumped storage, and minimal reporting requirements. The Applicant's recent installation of two battery storage facilities to support the projects provides even greater flexibility.**

12. Page 1-114. The Applicant describes flow management within the greater Ripogenus-Penobscot Mills system. The upper West Branch is a highly altered system and is likely to remain so for this relicensing cycle and beyond. The task is to manage it intelligently and effectively so as to balance project benefits and harms. The FERC relicensing process exists to provide periodic re-examination of flows and other aspects of project operations. **Data to enable effective analysis of flows is the key information requirement for relicensing of both the Ripogenus and Penobscot Mills projects. I**t should also be noted that the flows and water temperatures at both projects are extremely complex. At Ripogenus Dam, water may travel downstream through the water tunnel, over the dam, through the deep gate or over the sluiceway; at Penobscot Mills, the complexity of the multiple impoundments and generation facilities drive the difficulty. These factors will need to be considered in studies.

13. Page 4-11 and subsequent. Section 4 describes existing project facilities. **Nowhere in the PAD does it describe how operations are monitored and controlled. Both project operations are controlled remotely from Brookfield's control center in Marlborough, Massachusetts.** When asked at the morning Scoping Teleconference on September 9 how many other facilities were controlled from that location, Brookfield did not give a number. When asked where

[12] Environ. Sci. Technol. 2013, 47, 15, 8130–8137, Sediment Trapping by Dams Creates Methane Emission Hot Spots, accessed at https://pubs.acs.org/doi/full/10.1021/es4003907; Nature Communications volume 10, Article number: 1375 (2019) Eutrophication will increase methane emissions from lakes and impoundments during the 21st century accessed at https://www.nature.com/articles/s41467-019-09100-5; and others.

[13] PAD, page 4-16.

maintenance crews were located to address problems at McKay Station, Brookfield responded that is was in Millinocket about an hour away. Section 4 also does NOT contain a description of how emergency flow are maintained during times of generating unit outage. This is significant because there were three recent low flow events below Ripogenus Dam within a three-week period.[14] Minimum time to correct generator outage problems appears to be over two hours. The remote control of project operations and distance from the project of response crews to Ripogenus Dam and McKay Station underlines the importance of obtaining operational data for the projects. If FERC's investigation into the cause of these outages does not reveal their source, then a FERC Study should look into how operations for the projects are being controlled.

14. Page 4-13. The description should also include that the impoundment created by Ripogenus Dam is Maine's third largest.

15. Page 4-24 and subsequent do NOT mention the dewatering (other than leakage) of 4.5 miles of the main stem of the West Branch of the Penobscot below Stone Dam.

16. Page 4-44. Ambajejus Lake needs to be added to the graphic. Although referred to repeatedly in the subsequent description, it only appears in the legend of figure 4.4-1.

17. Page 4-50. Note that Millinocket Lake levels can vary between 470 and 480 feet. Data is needed to verify that this is occurring.

18. Page 4-52. The tables provided show average monthly flows for the projects. This is of little use in determining how flows vary on time scales ranging from instantaneous to daily to weekly to between years, and do not indicate the frequency and magnitude of flow excursions that differ from these averages.

**19.** Page 4-54, Article 54. Status states: "*GLHA continues to provide the required minimum flows via leakage and the sluice gates.*" **The sluice gate flows were designed to provide 100 cfs "fishing flows" from July 1 to September 30 to the significantly dewatered reach of the main stem of the West Branch of the Penobscot that makeup fully half of the waters in Ripogenus Gorge. During the last relicensing, use of water from the sluice gates was requested by Great Northern Paper and specified. The sluice gates provide warm water from the surface of the impoundment.[15] The benefits to the fishery would be greater if deep gate releases of colder water were used.**

20. Page 5-44. Does NOT describe the dewatering of the main stem of the West Branch of the Penobscot River below Stone Dam.

21. Page 5-57. Discusses the Use Attainability Analysis (UAA) for the Ripogenus impoundment, and 38 MRS §464-9(A), noting: "*The project creates an impoundment that is subject to water level fluctuations that have an effect on the habitat and aquatic life in the littoral zone so that the habitat and aquatic life differ significantly from that found in an unimpounded great*

[14] TU letter Subject: Maine Council of Trout Unlimited Report of Observed Low Flow Events for the Ripogenus Project (P-2572) dated September 21,2021. FERC created sub-docket P-2572-134 to track correspondence relating to this.
[15] Paul Johnson (former MDIFW fisheries biologist eComment of October 8, 2021: "Flows in the Upper Gorge between Ripogenus Dam and McKay Station have not met the objectives for this section of river for the past 25 years! Article 401 of the current license requires a July 1 - September 30 discharge of 100 cfs into the Upper Gorge to provide a cool flow that would attract adult salmon and increase fishing opportunity in the gorge during this period. The recommendation for this flow and its timing was based on observations in years prior to the 1990's, when minimum flows discharged to the West Branch with McKay Station shut down were provided through a deep gate in Ripogenus Dam – hence the cool water. Unfortunately, for the past 25 years the 3-month discharge has been through a small sluice gate that provides warm, surface water to the Upper Gorge, defeating the purpose of Article 401 – 25 years of lost mitigation/enhancement."

*pond;*" Current fluctuations in water levels need to be determined and compared to those upon which the UAA was based.

**22.** Pages 5-87 and 88. **MDEP benthic macroinvertebrates monitoring was NOT conducted in the main stem of the West Branch of the Penobscot River below Stone Dam. Current MDEP protocols call for sampling in bypass reaches.**

23. Page 5-94. "*Both the Ripogenus and Penobscot Mills Projects are within the native range of the brook trout. The brook trout (Salvelinus fontinalis) fishery in the West Branch declined during the 1950s as the landlocked salmon fishery increased in popularity (FERC 1996).*" **Brook trout are found in every county in Maine, co-exist with landlocked salmon throughout the range of landlocked salmon in Maine and are frequently sought and caught by West Branch Penobscot anglers.** Subsequent paragraphs reference two studies requested but not provided: FishBase 2021c and FERC 1996.[16] This underlines the need for referenced studies to be provided, NOT summarized.

24. Page 5-104 and subsequent. IBI (Index of Biological Integrity) is referred to as a source for fish assemblage data. This is another document referenced in the PAD and not provided. IBI for the Penobscot Mills Project reaches likely show serious damage to the biological health of the reaches. This is another reason why data summarized by the Applicant is inadequate.

25. Page 5-108. Center of page: "*…gill netting efforts. Fish species collected during boat electrofishing surveys in littoral habitats included predominantly white sucker and white perch (GNNC 1991a)*." These data are 30 years old, and there are multiple reasons to believe that species composition may have changed during this period: (1) Maine has seen an enormous increase in the spread of non-native fish species as a result of deliberate illegal introductions; incidental introductions due to use of live bait; and migration from existing established populations. (2) Climate change may very well have altered habitat suitability for some sensitive species. (3) Project operations may have change the magnitude or duration of reservoir drawdowns that limit the amount littoral habitat and oxygenated deep water available in the impoundment. Anecdotal reports indicate that the reservoir has not been fully filled since 2019. Any assessment of the projects impacts and appropriate future operation must start with an understanding of today's baseline fish populations.

**26.** Page 5-108. Following paragraph: *"Non-native species such as northern pike and smallmouth bass have not been documented in the Ripogenus Project area, although they have been documented in more downstream reaches of the Penobscot River Basin. There are no anadromous fish populations present in the Ripogenus Project area. A fish species list is provided in Table 5.4-4."* **Table 5.4-4 contains historical data. Table 5.4-6 on page 5-118 contains data from 1986-1989 Fish Assemblage Surveys. Invasive species continue to be spread throughout the state. The only way to know whether these species are present is to conduct fish assemblage studies.**

**27.** Page 5-110: ""*During the previous relicensing effort, the Licensee proposed to provide stable minimum flows from McKay Station into the West Branch to promote landlocked salmon spawning and egg incubation. As such, pursuant to License Article 402, GLHA provides landlocked salmon spawning flows of at least 1,422 cfs (or inflow, but not less than 1,300 cfs) from October 15 to November 15 and incubation flows greater than 1,422 cfs (or the spawning flow established for that year) from November 16 through June 7. These flows were developed to prevent exposure and desiccation of salmon redds and enhance overall*

[16] TU Letter dated October 2, 2021.

*reproductive success (FERC 1996). Further, GLHA implements automatic, short-term "outage" flows of 400 cfs downstream of McKay Station during station outages as a temporary means for protecting aquatic habitat in downstream reaches of the West Branch. Stable flows resulting from water management at McKay Station help to maintain constant, high quality flow conditions downstream."* **That "*stable flows*" are being provided remains a matter in question. Three low flow events were documented during a three-week period by TU in 2021.[17]**

28. Page 5-117: "*…higher flows (50 to 100 cfs) were shown to improve habitat for landlocked salmon.*" **Higher flows would also provide a buffering mechanism for the low flow events that we have repeatedly referred to.**

29. Page 5-120: "*There are recent reports that smallmouth bass have become illegally introduced to the impoundment (Kevin Dunham, MDIFW, personal communication, May 2021)."* This statement refers to Table 5.4-7, Fish Assemblage Data from North Twin Impoundment (2016-2017) which does NOT list smallmouth bass. **It is incongruous for the Applicant to urge the Commission to accept 30-year-old data when this shows that even four-year-old data may be outdated.**

30. Page 5-125 and 126: Referring to the waters of Lower Millinocket Stream and West Branch (Millinocket Tailrace to Dolby Pond): "*This reach of river only supports warmwater species (GNNC 1991b).*" This includes the dewatered reach of the West Branch of the Penobscot River. Since the Great Falls occurs downstream near the confluence with Shad Pond, one would expect for this reach to support at least a mixed cold water and warm water fish assemblage due to increased oxygenation if the reach were not dewatered. This is more evidence of how disruptive project operations are to the fisheries environment.

31. Page 5-128: Table 5.4-11 Fish Assemblage Data from 2004 IBI Sampling in Millinocket Stream. This reach is accessible from Shad Pond. **American shad were not sampled. There are no shad in Shad Pond due to the presence of downstream dams and the lack of effective fish passage.**

32. Page 5-129: "*The Back Channel is a 4.5-mile-long reach downstream of Stone Dam (Millinocket impoundment) that flows into Shad Pond. The Back Channel is bracketed by Stone Dam and Grand Falls, which is a natural falls located approximately 2.7 miles below Stone Dam and a barrier to upstream movement of warmwater species, sea run alosines (shad and river herring), and juvenile salmon (GNNC 1991b) (Photo 5.4-2). The reach receives inflow from various tributaries as well as from Quakish Lake, which in the summer is composed of warm limnetic surface water spill at Stone Dam.*" The warm water input that is described (when present) contributes to the lack of salmonids. See specific comment 30 above. Also note that **no specific fish assemblage is provided for the mostly dewatered section. This section is NOT 'fishable or swimmable' as required by the Clean Water Act.**

33. Page 5-132: *"Changes in macroinvertebrate composition are related to distance downstream from the Ripogenus Dam, likely due to a diminishing supply of plankton and other particulate material in water discharged from McKay Station."* TU members have observed so many stoneflies flying out of the gorge below McKay Station that they were being caught on the wing and eaten by flocks of seagulls. The watered section of Ripogenus Gorge is one of the most productive stretches in Maine waters in terms of macro-invertebrate production, and this is a major factor in maintaining the remarkable land-locked salmon fishery below McKay

[17] TU letter dated September 21,2021.

Station. **Dewatering the gorge above the powerhouse, about half the total length of the gorge, except for leakage flows for three months out of the year and only 100 cfs through the sluiceway for the summer months greatly decreases potential macro-invertebrate production. Instream Flow Incremental Methodology (IFIM) studies may show that there is some suitable for landlocked salmon at different stages of development, but ignore profound project effects on potential macro-invertebrate populations.**

34. Page 5-169: Third bullet point does NOT describe any of the effects of the dewatering of the main stem of the West Branch of the Penobscot River below Stone Dam. One would expect that significant effects have occurred as a result of the perennial dewatering since 1996, and the vegetation present seem to support this. The current condition needs to be assessed by formal studies to evaluate water quality and appropriate flows.

35. Page 5-206: Table 5.8-1 lists only Formal FERC-Approved Project Recreation Sites for the Ripogenus Project. Many more recreation sites exist that are affected by project operations. These include drift boat pullouts, formal campgrounds, parking pulloffs, etc.

**36.** Page 5-247: *"The Upper Gorge itself is very scenic with stretches containing sheer vertical walls that rise 75 feet above the riverbed."* This is true as stated, but **the description omits the fact that except for high flow conditions, the upper gorge is only watered with leakage flows for nine months out of the year, 100cfs during the summer months. This significantly diminishes the aesthetic qualities of the gorge.** While TU's interests lie primarily with the fishery, the aesthetics of the area are a factor in our members' use and enjoyment of the area.

**37.** Page 5-252 and subsequent: This describes the historical context of the projects. It should be noted that **a significant part of the original justification for damming Ripogenus Gorge was to provide electricity to power the trains that hauled the logs from the region, replacing coal.[18] Fossil fuel continues to be the prime mover of cordage from the region.**

38. Page 6-3, Water Quality – Upper Gorge: Water quality of the Upper Gorge (half of the gorge is above McKay Station) needs to be revisited during this relicensing cycle. 100 CFS fishing flows during the summer originally was for a deep gate release instead of the sluiceway. Water source affects temperature and dissolved oxygenation levels. 12 cfs leakage flows do NOT provide "structure and function" as required by current Maine environmental law and policy. Past IFIM studies looked only at land-locked salmon at certain stages of development and ignored effects on macro-invertebrate populations, a main factor in the abundant fishery. MDEP studies to gather this information are supported by TU.

**39.** Page 6-4, Water Quality - Impoundment Aquatic Life: The **Applicant states that there is no change in operations or effects on aquatic life. Reports to the contrary and effects to the fishery say otherwise.** This statement is simply unsupported by current data. The applicant has not provided operational data demonstrating that operations have not changed; the applicant has not provided aquatic life data that show that the aquatic community has not changed.

40. Page 6-4, Baseline Fisheries - West Branch (below McKay Station): "*Significant amounts of information/data on West Branch fisheries already exist, as fisheries data were collected during the last relicensing and has continued to be collected by the GLHA and MDIFW. The existing fisheries data are sufficient to characterize the existing West Branch fishery. As there*

[18] West Branch Water May Move Maine Railroad Trains; Bangor Daily News, Friday, December 8, 1916; page 14. "Million Dollar Barrier at Ripogenus Gorge That Will Change the Face of Nature BY Flooding Seven Lakes Into One…"

*have been no changes to Project operations, there are no expected changes or impacts to West Branch fisheries."* There simply is no way to assess the effects of project operations without current operational information.

**41.** Page 6-12, Penobscot Mills - Back Channel Instream Flows: This reach is **the largely dewatered West Branch of the Penobscot. It does NOT maintain the structure and function required by Maine environmental law. That the reach only supports warm water species [19] despite how far north demonstrates the degree to which it is degraded by lack of instream flow.**

**The following specific comments deal with the Applicant's list of potential studies:**

42. Page 6-19, Water Quality Study - Ripogenus: The applicant lists the suite of studies normally required by MDEP.

**43.** Page 6-19, **Macroinvertebrate Survey - Ripogenus: The applicant proposes only one macro-invertebrate study downstream of McKay Station. Current MDEP protocols require sampling "*in any bypassed region created by the project.*"[20] This is essential to assess the effects of reduced flows in the upper Ripogenus Gorge.**

44. Page 6-19, Recreation Facility Inventory and Condition Assessment. Past studies conducted by Brookfield have been quite selective in what was included. The second bullet: "Desktop research and inventory of regional recreational facilities, opportunities, and management plans." is inadequate and of minimal utility in this rural setting. "The third bullet: "I*dentify gaps, improvements, or use needs within the Project boundary*." simply cannot be accomplished using this minimal methodology. Interviews, and focus groups are absolutely required to assess current recreational requirements for the project area and vicinity, both of which are highly affected by project operations. A recreational inventory will ignore many recreational amenities that Mainers have enjoyed for many years as well as the aesthetics involved with the project. **Well established methodology exists to conduct a study appropriate to the projects: Flows and Recreation, A guide to studies for river professionals; Doug Whittaker, Ph.D, Confluence Research and Consulting; Bo Shelby, Ph.D., Oregon State University; John Gangemi, American Whitewater / OASIS Environmental; October 2005.** Please note that this now standard methodology was NOT published until after the last relicensing.

45. Page 6-20, Macroinvertebrate Survey: **No macro-invertebrate survey is proposed for the main stem of the West Branch below Stone Dam.** This omission runs contrary to MDEP protocol.[21] Failure to conduct such a study will result in a deficient Environmental Assessment (EA). Comparing macro-invertebrate populations below Stone Dam, the main stem of the West Branch of the Penobscot River with those of Millinocket Stream where the vast majority of flows are currently directed will highlight how profound the continuing project impacts are.

**Conclusions and Recommendations**

The Applicant is proposing to treat the relicensings of these projects as if the fact that the last relicensings were conducted after the passage of the Electric Consumers Protection Act of 1986 absolves the Applicant from the responsibility to fulfill the requirements of the Integrated Licensing Process (ILP).

[19] PAD, page 5-126, Table 5.4-10. No salmonids are listed.
[20] DEP Sampling Protocol For Hydropower Studies dated December 2017.
[21] Ibid.

This is not a FERC-exempt project whose operating conditions continue in perpetuity. It is a licensed project where operations, benefits, and impact are re-evaluated periodically through the re-licensing process. Failure to conduct studies needed for FERC to identify project harms and balance them with project benefits would be contrary to public law, policy and practice. NEPA requires the studies be "Well Considered" and "Fully Informed." Thirty-year-old studies can be neither.

The Applicant's contention that data collected, studies accomplished and MP&E measures adopted are sufficient for submission for this relicensing is unsupported. Much has changed in the intervening years. This includes changes in: management through a succession of three owners, recreational use of the resource - even the climate itself. Only through analysis of data by collected by dedicated study will show if there have been effects, and (if there have been) suggest adaptive measures to address them.

Anyone who has spent time in the region from west of Millinocket to the Ripogenus-Chesuncook impoundment is quite aware that the impoundment has been perennially dewatered, that sections of the main stem of the West Branch of the Penobscot River are largely dewatered both below McKay Station and Stone Dam. Comments verbalized at the Scoping Meetings and written since then leave little doubt that this is what is occurring; the Applicant's submission attempts to minimize or ignore them.

**The PAD says very little about flow studies, and these are most important.** Numerous stakeholders have stated that project operations have changed, and you would expect this to be the case when there have been three owners since the last relicensing, and when the purpose of the dams has changed from providing power to working paper mills who owned them to producing power to sell on the grid. Climate change, including increasingly dry summers, is a factor as well. The relicensing process is the only opportunity to assess these changes and determine whether changing conditions alter the projects' benefits and impacts, and suggest changes in operations.

The Commission has NOT answered the requests of four resource protection agencies, PIN and TU for 10 years of operational data, most recently reiterated by e-mail from the National Marine Fisheries Service on October 5, 2021:

> *"Mr. Creamer - Your September 28, 2021 Response to Extension of Time and Additional Public Meeting Requests, and Request for Information for the Ripogenus Project No. 2572-133 and the Penobscot Mills Project No. 2458-247 did not address our September 13, 2012 request for operations data for these projects. Specifically, NMFS requested:*
>
> *We also request that you require the Applicant provide us with 10 years of operations data for each project including: 1) daily impoundment elevations; 2) daily outflows for each project (minimum, maximum, and average daily discharge). These data are critical for us to develop comments on the PAD and identify data gaps and any new studies.*
>
> *Can you please update us concerning the status of this request?*
>
> *Thank you, Jeff Murphy."*

Even if the information were to have been provided immediately, it would leave the agencies without adequate time to conduct meaningful analysis of the data.

Repeated observations that there are changes to prevailing lake levels in the Ripogenus-Chesuncook impoundment should be assessed with operational data. If operations and/or natural hydrology have changed since the 1996 license, the analysis and assumptions that informed 1996 licenses, 401 certificates, and the Use Attainability Analysis must be re-examined. Conditions are so poor that smelt populations have likely suffered and must be reexamined by scientific study.

TU sees the following as studies as absolutely essential to the preparation of an EA for the projects:

1. For the Ripogenus Project:

a. Studies of aquatic life in the Ripogenus-Chesuncook impoundment to determine if species populations have changed since the last relicensing.

While 38 MRS §464-9(A) allows changes to the littoral zone, the extreme conditions described by multiple comments indicate that the limnetic and profundal zones may be seriously impacted as well.

b. Flow Studies for the Ripogenus Dam for both above and below McKay Station

There have been three different owners since the last relicensing: Great Northern Paper, and Great Lakes Hydro both before and after its purchase by Brookfield. These questions need to be answered: Has the McKay Station been operated differently during the ownership periods, is the perceived peaking operation actually occurring, are perceptions all due to climate change?

c. Temperature studies below both above and below McKay Station

The dam facilities are complex and care must be taken to ensure that water tunnel, over the dam, deep gate and over the dam scenarios are considered as well as the inter-relationships between sources as water from the different sources will have different temperatures and this will vary dependent on time of the year.

d. Macro-invertebrate and DO studies for both above and below McKay Station with comparisons of the two different reaches.
e. A proper Recreational Study to replace the perfunctory Recreational Facilities Inventory that the Applicant has proposed.
f. Detailed analysis of the outflows of McKay Station to determine the cause, frequency, magnitude and duration of the low flow events below Ripogenus Dam.

This study should consist of analyzing operational data against the flow requirements detailed in the PAD.[22] This analysis can be accomplished by testing Brookfield's operational data against minimum flow requirements, something readily accomplished by computer algorithm.

g. A study revisiting the adequacy of 400 cfs as a flow adequate to prevent stranding and dewatering of salmonid redds during generator outage.
h. If warranted by study f above, an engineering study to determine means to improve the stability of the flows from McKay Station.

2. For the Penobscot Mills Project:
   a. Flow Studies for the West Branch of the Penobscot River for both Millinocket Stream and the waters below Stone Dam.
   b. Temperature studies for both Millinocket Stream and the waters below Stone Dam.
   c. Macro-invertebrate and DO studies for both Millinocket Stream and the waters below Stone Dam.
   d. A proper Recreational Study to replace the perfunctory Recreational Facilities Inventory that the Applicant has proposed.

Accordingly, TU supports the study requests of:

1. MDIFW[23] for these proposed studies that bear directly on their ability to manage resident species:

   1) Exposed Aquatic Habitat Assessment

   2) Landlocked Salmon Habitat Use/Spawning Study—Penobscot Mills Project

[22] PAD, page 4-45, Minimum Flow Requirements downstream of McKay Station for the Ripogenus Project.
[23] MDIFW letter dated October 8, 2021.

3) Minimum Flow Analysis of Back Channel [West Branch below Stone Dam]

4) Macroinvertebrates Study Request—Ripogenus Project

2. NMFS[24] for these key flow-related studies. While these studies are fully justified on the basis of effects on Atlantic salmon, the information would be invaluable for determining the effects of flows on resident fish species and other aquatic organisms as well:

1) A Study to Evaluate the Effects of Operating the Penobscot Mills and Ripogenus Dams on the Hydrology of the West Branch and Mainstem Penobscot River Using an Indicators of Hydrologic Alteration Model (IHA)

2) A Study to Evaluate Project Effects on River Temperature in the West Branch and Mainstem Penobscot River

3) A Study to Evaluate Future Flow and Water Temperature Scenarios[25]

3. MDMR[26] for studies for American eels and passage alternatives for all historic anadromous species:

1) Three-Dimensional Computational Fluid Dynamics (CFD) Modeling Upstream and Downstream of the Discharge and in the Vicinity of Powerhouse Forebays

2) Upstream Juvenile Eel Assessment

3) Downstream American Eel Passage Assessment

4) Downstream Passage Alternatives Study

5) Upstream Passage Alternatives Study

6) Evaluation of the Size of American Eels and the Timing of their Downstream Migratory Movements

4. USFWS[27] for the following due to their potential positive impact on the ecology of the entire Penobscot Watershed:

1) Upstream American Eel Passage Assessment

2) Downstream American Eel Passage Assessment

3) Downstream Passage Alternatives Study [eels]

4) Evaluation of the Size of American Eels and the Timing of their Downstream Migratory Movements

5) Freshwater Mussel Survey

5. American River and the Appalachian Mountain Club[28] for the following: aesthetics and other uses are also important to TU members. The first study is absolutely essential to identify changes that have occurred since the last license was issued and to identify needs for the next licensing period. Whitewater flows have proven to be highly compatible with fishing-related activities on the West Branch. Care must be taken to assure that commensurate minimum flows are adopted to prevent the stranding of aquatic organisms following cessation of these flows:

[24] NMFS letter dated October 8, 2021
[25] TU believes this is the key study for the Rigogenus - Penobscot Mills relicensings
[26] MDMR letter dated October 8, 2021.
[27] USFWS letter dated October 7, 2021.
[28] Joint American River and the Appalachian Mountain Club letter dated October 8, 2021.

1) Recreation Facility Inventory, Recreation Use and Needs Assessment, Aesthetics and Reservoir Surface Area Assessment Study

2) Controlled-flow Whitewater Boating and Access Study

3) Aesthetics Resources Study

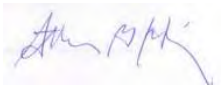
6. The standard MDEP suite of study requests conditioned to provide sampling in the generally dewatered reaches of the main stem of the West Branch of the Penobscot River in upper Ripogenus Gorge and below Stone Dam. While the specific legislation[29] allows major changes to the littoral zone, with the severe changes to impoundment levels that have been extensively documented by numerous photographs and comments, the limnetic and profundal zones have likely been impacted as well. Study is indicated, and this does not represent a conflict with the statutory language

TU submits the following Requests for Information (RFIs):

1. That Brookfield clarify ownership by itself or any of its partners of the parcel containing the stream bed of the West Branch of the Penobscot and the margins thereof as shown in Attachment A[30] as this may affect the status of recreational access downstream of Ripogenus Dam.
2. Trout Unlimited reiterates its request for the specific referenced studies that we requested, so that we may understand the existing information and likely draft additional study requests. (Attachment B). TU additionally requests that FERC criteria for additional studies be applied more permissively than is generally the case to any requests that the agencies, PIN or NGO may submit later in the process if/when important information is still lacking.
3. Thirty years of operational data for all generation facilities. This is over and above agency requests in order to enable a comparison of operations among the three corporate entities that have owned and operated the Ripogenus Project during that time frame. That this data exists for at least some of this timeframe is illustrated by the graphic included as Attachment C, Figure 1. TU requests that generation data for all generation facilities be provided as delimited data files including date, time and generation flow at 5 minute intervals; and daily water level data for all impoundments.

TU submits the following FERC Study Requests:

1. Ripogenus Flow Excursion Study (Attachment C)
2. Fish assemblage studies for the waters of both projects. Fish assemblage studies are normally approved for relicensings. This will provide current information. Use of established, consistent methodology will establish baselines for comparison for future relicensings of the projects. The specific studies requested (Attachments D through M) are:
    1) Ripogenus-Chesuncook Impoundment Baseline Fisheries Assemblage Study
    2) West Branch of the Penobscot River Below Ripogenus Dam Baseline Fisheries Assemblage Study
    3) North Twin Impoundment Baseline Fisheries Assemblage Study
    4) Millinocket Lake Baseline Fisheries Assemblage Study
    5) Dolby Pond Baseline Fisheries Assemblage Study



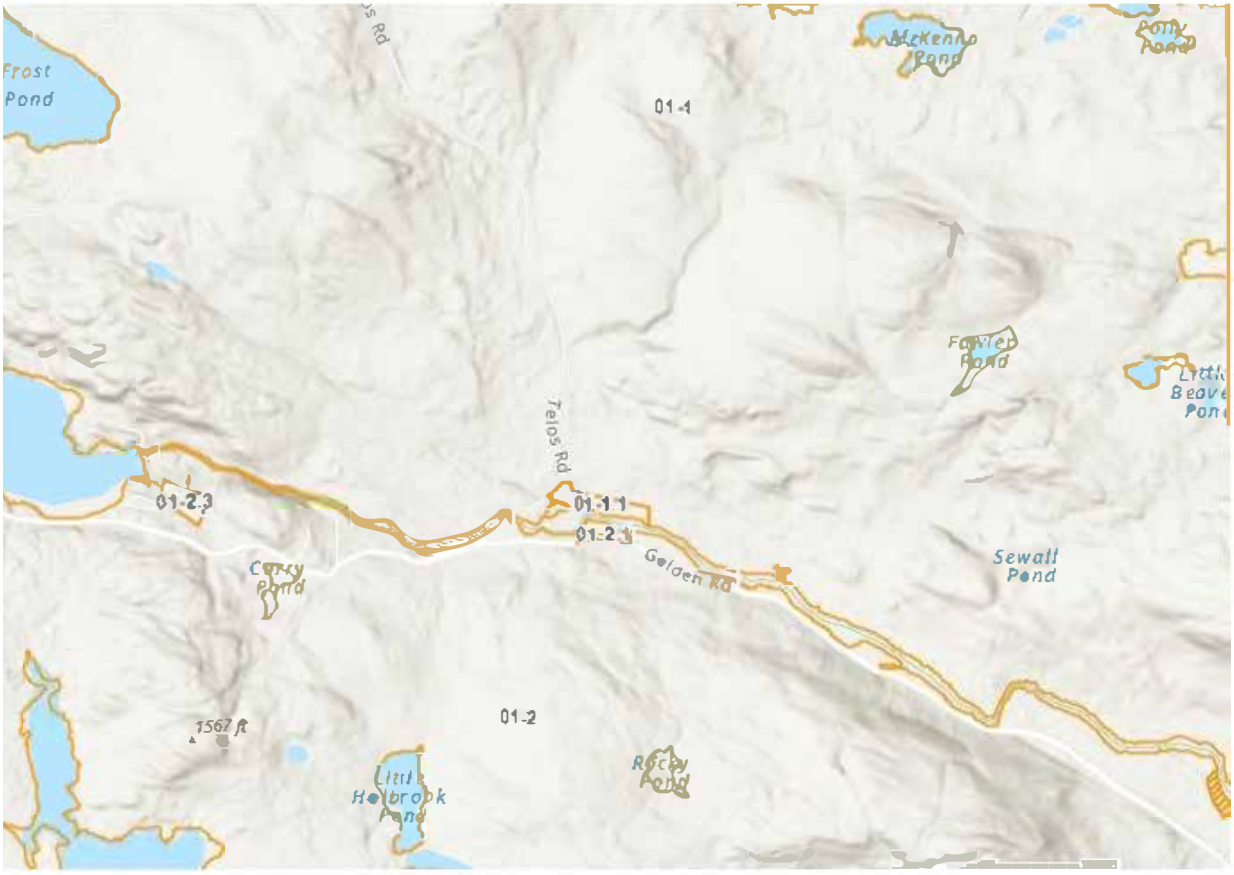
[29] 38 MRS §464-9(A) "T*he project creates an impoundment that is subject to water level fluctuations that have an effect on the habitat and aquatic life in the littoral zone so that the habitat and aquatic life differ significantly from that found in an unimpounded great pond*."

[30] Map of Parcels downstream of Ripogenus Dam copied from the LUPC Zoning and Parcel Viewer accessed at https://maine.maps.arcgis.com/apps/webappviewer/index.html?id=89f9a143c79f4349a40a3ff77975f17a

6) East Millinocket Impoundment Baseline Fisheries Assemblage Study
7) West Branch of the Penobscot River North Twin Dam to Quakish Lake Baseline Fisheries assemblage Study
8) Lower Millinocket Stream and West Branch (Millinocket Tailrace to Dolby Pond) including Shad Pond Baseline Fisheries Assemblage Study
9) Study Request: Millinocket Stream (Millinocket Lake Storage Dam to Millinocket Development) Baseline Fisheries Assemblage Study
10) West Branch of the Penobscot River Below Stone Dam Baseline Fisheries Assemblage Study

Maine TU Council appreciates the opportunity to provide these comments on these important projects and hopes that the Commission will act to allow the resource protection agencies have the information needed to identify potential harms to the resource and thus enable the Commission to balance project harms and benefits.

Respectfully,



Stephen G. Heinz
Maine TU Council FERC Coordinator

**Study Request: Ripogenus Flow Excursion Study**

**1. Study Goals and Objectives.**
Document the stability of flows from Ripogenus Dam as they compare to the licensed project minimums. Conduct a 400 cfs flow demonstration to determine the impacts of "generator outage flow" on aquatic organisms.

**2. Relevant resource management goals.** (Under §5.9(b)(3) If the requester is a not a source agency, explain any relevant public Interest.)

Maine's rivers, great ponds and wildlife are, by law, public resources. Sebago Chapter members use the area for fishing and other recreational activities, and thus have a direct interest in the waters affected by project operations.

The minimum flows governing the Ripogenus Project are complex. The PAD describes them on page 4-45 with the exception of flows into the upper gorge on page 4-43: "*minimum flow of 100 cfs is released from Ripogenus Dam into the bypassed reach (Upper Gorge) from July 1 through September 30 annually. Consistent with the August 19, 1997 FERC order approving and modifying the Water Management Plan, the minimum flows into the Upper Gorge are released through the sluice gates at the north end of the dam. During the remainder of the year, a minimum flow of 12 cfs is provided through leakage from Ripogenus Dam into the Upper Gorge. Releases from the Ripogenus Project enter the West Branch and flow 21 miles downstream (from McKay Station) into Ambajejus Lake, which is part of the North Twin Development of the Penobscot Mills Project."* Minimum flows are prescribed for fish spawning or incubation [of salmonid redds], whitewater, station outages and other times.

**3. The requestor, Sebago TU, is a non-governmental organization (NGO).**

**4. Background and Existing Information.** Existing information concerning the subject of the study proposal, and the need for additional information.

The PAD on page 6-5 states: *"Establishment of minimum flow regime for McKay Station through the previous relicensing enhanced fish and aquatic habitat in the West Branch, including spawning and rearing habitat for landlocked salmon. As there have been no changes to Project operations and minimum flows continue to be provided, it is expected that the existing flow regime from McKay Station will continue to support the existing West Branch fishery."* TU reported three low flow events that occurred between late August of 2021 and Mid-September [Maine Council of Trout Unlimited Report of Observed Low Flow Events for the Ripogenus Project (P-2572) dated September 21, 2021]. Sarah Sindo who works downstream of Ripogenus Dam during the summer reported: "*I have been witness to at least 1-2 low water excursion events each of the seven seasons I have been here. An outage will occur at McKay Station resulting in a downriver flow of 300-400 cfs, which comes from Ripogenus Dam. The river will stay at this level for 2-4 hours before McKay Station is restored. Not all, but some of these low water excursions, I have witnessed crayfish and other invertebrates in the now dewatered sections of the river, mostly along the shoreline.*"[31] Apparently, more of these events are occurring than are being reported. Minimum flows requirements make little difference if they are not adhered to.

[31] Sarah Sindo eComment of October 8, 2021

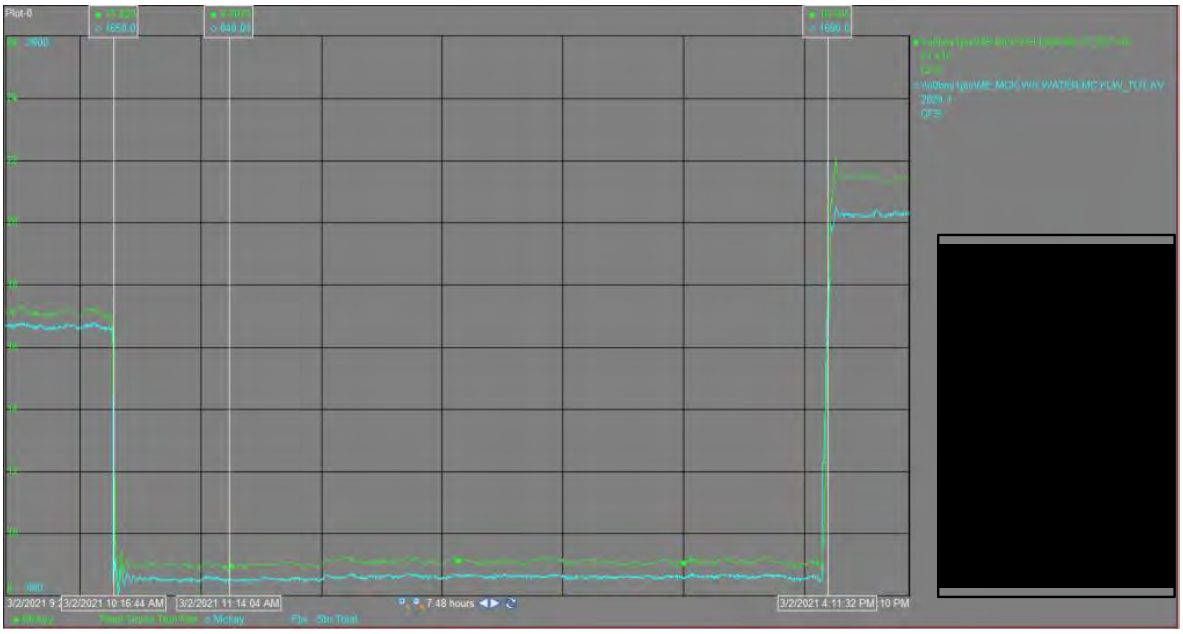
**5. Nexus between Project operation and effects on the resource to be studied.**

Inability of the operator and/or project facilities to maintain minimum flows can have a profound effect of the downstream environment and the organisms that live in it.

**6. Explain how the proposed study is consistent with generally accepted practice in the scientific community.**

Operational data is available from the Ripogenus and has been supplied by Brookfield to document past flow excursions including the one that was reported March 12, 2021. Figure 1 from that report shows the data available. The Excursion Report included graphical data for both flow and power produced at a fine level of detail. Flow data tables could be examined by computer algorithms derived from minimum flow requirements described above and exact dates of excursions, type, magnitude and duration determined. This task has been well within the state of the art for many decades. Regarding the flow demonstration, Brookfield recently proposed and then cancelled a somewhat similar demonstration flow event for its Wyman Project. [email -From: Seyfried, Jason <Jason.Seyfried@brookfieldrenewable.com>; Sent: Tuesday, February 16, 2021 3:35 PM; Subject: Wyman Project (FERC No. 2329-ME) Temporary Flow Variance Request - Agency Consultation]

**7. Describe considerations of level of effort and cost, as applicable, and why proposed study alternatives would not be sufficient to meet the stated information needs.**



This would be a desktop study except for 400 cfs demonstration. The estimated cost for the Ripogenus Flow Excursion Study is estimated to be approximately $10,000.

# Attachment D

**Study Request: Ripogenus-Chesuncook Impoundment Baseline Fisheries Assemblage Study**

**1. Study Goals and Objectives.**
Document the fisheries assemblage in the Project waters for comparison with past studies.

**2. Relevant resource management goals.** (Under §5.9(b)(3) If the requester is a not a resource agency, explain any relevant public Interest.)

Maine's rivers, great ponds and wildlife are, by law, public resources. Sebago Chapter members use the area for fishing and other recreational activities, and thus have a direct interest in the waters affected by project operations.

MDIFW manages the Ripogenus-Chesuncook Reservoir as a coldwater fishery. The objective of the study is to document the existing fisheries assemblage and to collect information about the distribution and abundance of salmonids and other fish species present in the Project waters. Data collected will document the relative abundance and distribution of cold and warm water fish species present in the Project area, evaluate size class information (i.e., adult, juvenile, young-of-year), and species diversity. Size-quality of landlocked salmon has deteriorated in the impoundment causing adoption of special fishing regulations: "*No size or bag limit on salmon less than 16 inches.*"

**3. The requestor, Sebago TU, is a non-governmental organization (NGO).**

**4. Background and Existing Information.** Existing information concerning the subject of the study proposal, and the need for additional information.

The PAD references assemblage data from the last license application: Report on Studies of The Habitat, Fish Populations, and Fisheries of The Ripogenus Project (FERC No. 2572) Study Area, West Branch page 18, table 5. This data was collected in 1960, 1970, and 1981. Netting effort required (linear ft of gill net x hours fished) ranged from 10,700 to 40,350. The most recent data is now forty-years old. Apparent changes in project operations and/or climate, and possible introduction of invasive fish species including smallmouth bass and northern pike make resampling important.

**5. Nexus between Project operation and effects on the resource to be studied.**

The Ripoganus Project Project provides lacustrine and riverine fish habitats that support fish populations, which may be affected by operations. Collection of baseline fisheries information will provide a better understanding of the potential effects of continued operation on resident fish species, especially salmonids including smelt. Smelt populations are known to be the most important forage for landlocked salmon both above and below Ripogenus Dam .

**6. Explain how the proposed study is consistent with generally accepted practice in the scientific community.**

Gill netting is a standard, passive fish sampling method for providing baseline fisheries data.

**7. Describe considerations of level of effort and cost, as applicable, and why proposed study alternatives would not be sufficient to meet the stated information needs.**

The level of effort should be consistent with that of past studies in terms of linear feet of gill net and hours fished. The estimated cost for the baseline fisheries assemblage survey is approximately $20,000.

**Reference:**

Report on Studies of The Habitat, Fish Populations, and Fisheries of The Ripogenus Project (FERC No. 2572) Study Area, West Branch page 18, table 5.

# Attachment E

**Study Request: West Branch of the Penobscot River Below Ripogenus Dam Baseline Fisheries Assemblage Study**

**1. Study Goals and Objectives.**
Document the fisheries assemblage in the Project waters.

**2. Relevant resource management goals.** (Under §5.9(b)(3) If the requester is a not a resource agency, explain any relevant public Interest.)

Maine's rivers, great ponds and wildlife are, by law, public resources. Sebago Chapter members use the area for fishing and other recreational activities, and thus have a direct interest in the waters affected by project operations.

MDIFW manages the West Branch of the Penobscot River below Ripogenus Dam as a coldwater fishery. The objective of the study is to document the existing fisheries assemblage and to collect information about the distribution and abundance of salmonids and other fish species present in the Project waters. Data collected will document the relative abundance and distribution of cold and warm water fish species present in the Project area, evaluate size class information (i.e., adult, juvenile, young-of-year), and species diversity.

Data obtained may also be used as a basis of comparison for future relicensings.

**3. The requestor, Sebago TU, is a non-governmental organization (NGO).**

**4. Background and Existing Information.** Existing information concerning the subject of the study proposal, and the need for additional information.

The PAD documents the results of Fish Species Documented in the Ripogenus Impoundment and West Branch Downstream of the Ripogenus Dam during 1986-1989 Fish Assemblage Surveys. [PAD, page 5-119] Under the table containing the data, Table 5.4-6. The PAD notes: *"Source: GNNC 1991a, MBI 2005."* Apparently there is a Midwest Biodiversity Institute (MBI) Study in existence that has not been provided by the Applicant. Provision of the study would have enabled inclusion of additional detail in this study request.

**5. Nexus between Project operation and effects on the resource to be studied.**

The Ripogenus Project provides lacustrine and riverine fish habitats that support fish populations, which may be affected by operations. Collection of baseline fisheries information will provide a better understanding of the potential effects of continued operation on resident fish species, especially salmonids including smelt. Smelt populations are known to be the most important forage for landlocked salmon both above and below Ripogenus Dam .

**6. Explain how the proposed study is consistent with generally accepted practice in the scientific community.**

Electrofishing and gill netting are standard, fish sampling methods for providing baseline fisheries data. Electrofishing would be conducted in the reach above McKay Station, gill netting in the pools below such as the Little Eddy and Big Eddy.

**7. Describe considerations of level of effort and cost, as applicable, and why proposed study alternatives would not be sufficient to meet the stated information needs.**

The level of effort should be consistent with that of past electrofishing studies conducted by MBI. The estimated cost for the baseline fisheries assemblage survey is approximately $20,000.

**Study Request: North Twin Impoundment Baseline Fisheries Assemblage Study**

**1. Study Goals and Objectives.**
Document the fisheries assemblage in the Project waters.

**2. Relevant resource management goals.** (Under §5.9(b)(3) If the requester is a not a source agency, explain any relevant public Interest.)

Maine's rivers, great ponds and wildlife are, by law, public resources. Sebago Chapter members use the area for fishing and other recreational activities, and thus have a direct interest in the waters affected by project operations.

MDIFW manages the North Twin impoundment as a coldwater fishery. The objective of the study is to document the existing fisheries assemblage and to collect information about the distribution and abundance of salmonids and other fish species present in the Project waters. Data collected will document the relative abundance and distribution of cold and warm water fish species present in the Project area, evaluate size class information (i.e., adult, juvenile, young-of-year), and species diversity.

Data obtained may also be used as a basis of comparison for future relicensings.

**3. The requestor, Sebago TU, is a non-governmental organization (NGO).**

**4. Background and Existing Information.** Existing information concerning the subject of the study proposal, and the need for additional information.

The PAD on page 5-120 references "*MDIFW unpublished sampling data from 2016 and 2017*." This makes providing specifics on current information difficult. The Applicant notes: "*There are recent reports that smallmouth bass have become illegally introduced to the impoundment (Kevin Dunham, MDIFW, personal communication, May 2021).*" This indicates that the 2016-2017 data is already out of date.

**5. Nexus between Project operation and effects on the resource to be studied.**

The North Twin impoundment provides lacustrine fish habitat that supports fish populations, which may be affected by operations. Collection of baseline fisheries information will provide a better understanding of the potential effects of continued operation on resident fish species, especially salmonids including smelt.

**6. Explain how the proposed study is consistent with generally accepted practice in the scientific community.**

Gill netting is a standard, passive fish sampling method for providing baseline fisheries data.

**7. Describe considerations of level of effort and cost, as applicable, and why proposed study alternatives would not be sufficient to meet the stated information needs.**

The level of effort should be consistent with that of past electrofishing studies conducted by MBI. The estimated cost for the baseline fisheries assemblage survey is approximately $20,000.

**Study Request: Millinocket Lake Baseline Fisheries Assemblage Study**

**1. Study Goals and Objectives.**
Document the fisheries assemblage in the Project waters.

**2. Relevant resource management goals.** (Under §5.9(b)(3) If the requester is a not a source agency, explain any relevant public Interest.)
Maine's rivers, great ponds and wildlife are, by law, public resources. Sebago Chapter members use the area for fishing and other recreational activities, and thus have a direct interest in the waters affected by project operations.

MDIFW manages Millinocket Lake primarily as a coldwater fishery. The objective of the study is to document the existing fisheries assemblage and to collect information about the distribution and abundance of salmonids and other fish species present in the Project waters. Data collected will document the relative abundance and distribution of cold and warm water fish species present in the Project area, evaluate size class information (i.e., adult, juvenile, young-of-year), and species diversity.

Data obtained may also be used as a basis of comparison for future relicensings.

**3. The requestor, Sebago TU, is a non-governmental organization (NGO).**

**4. Background and Existing Information.** Existing information concerning the subject of the study proposal, and the need for additional information.

The PAD on page 5-122 references "*MDIFW unpublished sampling data from 2017 and 2018*." This makes providing specifics on current information difficult. The Applicant notes regarding the North Twin impoundment: "*There are recent reports that smallmouth bass have become illegally introduced to the impoundment (Kevin Dunham, MDIFW, personal communication, May 2021).*" As North Twin is immediately upstream and the Applicant states that other species are likely dropping down from these water, the 2017-2018 data is likely already out of date as well.

**5. Nexus between Project operation and effects on the resource to be studied.**

Millinocket Lake provides lacustrine fish habitat that supports fish populations, which may be affected by operations. Collection of baseline fisheries information will provide a better understanding of the potential effects of continued operation on resident fish species, especially salmonids including smelt.

**6. Explain how the proposed study is consistent with generally accepted practice in the scientific community.**

Gill netting is a standard, passive fish sampling method for providing baseline fisheries data.

**7. Describe considerations of level of effort and cost, as applicable, and why proposed study alternatives would not be sufficient to meet the stated information needs.**

The level of effort should be consistent with that of past electrofishing studies conducted by MBI. The estimated cost for the baseline fisheries assemblage survey is approximately $20,000.

**Study Request: Dolby Pond Baseline Fisheries Assemblage Study**

**1. Study Goals and Objectives.**
Document the fisheries assemblage in the Project waters.

**2. Relevant resource management goals.** (Under §5.9(b)(3) If the requester is a not a source agency, explain any relevant public Interest.)
Maine's rivers, great ponds and wildlife are, by law, public resources. Sebago Chapter members use the area for fishing and other recreational activities, and thus have a direct interest in the waters affected by project operations.

MDIFW manages Dolby Pond as a warm water fishery. The objective of the study is to document the existing fisheries assemblage and to collect information about the distribution and abundance of salmonids and other fish species present in the Project waters. Data collected will document the relative abundance and distribution of cold and warm water fish species present in the Project area, evaluate size class information (i.e., adult, juvenile, young-of-year), and species diversity.

Data obtained may also be used as a basis of comparison for future relicensings.

**3. The requestor, Sebago TU, is a non-governmental organization (NGO).**

**4. Background and Existing Information.** Existing information concerning the subject of the study proposal, and the need for additional information.

The PAD on page 5-123 references GNNC 1991b from the last license application. This data is now 40 years old. No table describing the results of the fish assemblage survey conducted then.

**5. Nexus between Project operation and effects on the resource to be studied.**
Dolby Pond provides lacustrine fish habitat that supports fish populations, which may be affected by operations. Collection of baseline fisheries information will provide a better understanding of the potential effects of continued operation on resident fish species.

**6. Explain how the proposed study is consistent with generally accepted practice in the scientific community.**

Gill netting is a standard, passive fish sampling method for providing baseline fisheries data.

**7. Describe considerations of level of effort and cost, as applicable, and why proposed study alternatives would not be sufficient to meet the stated information needs.**

The level of effort should be consistent with that of past electrofishing studies conducted by MBI. The estimated cost for the baseline fisheries assemblage survey is approximately $20,000.

**Study Request: West Branch of the Penobscot River North Twin Dam to Quakish Lake Baseline Fisheries Assemblage Study**

**1. Study Goals and Objectives.**
Document the fisheries assemblage in the Project waters.

**2. Relevant resource management goals.** (Under §5.9(b)(3) If the requester is a not a resource agency, explain any relevant public Interest.)

Maine's rivers, great ponds and wildlife are, by law, public resources. Sebago Chapter members use the area for fishing and other recreational activities, and thus have a direct interest in the waters affected by project operations.

MDIFW manages the West Branch of the Penobscot River North Twin Dam to Quakish Lake as a warm water fishery. The objective of the study is to document the existing fisheries assemblage and to collect information about the distribution and abundance of fish species present in the Project waters. Data collected will document the relative abundance and distribution of fish species present in the Project area, evaluate size class information (i.e., adult, juvenile, young-of-year), and species diversity.

Data obtained may also be used as a basis of comparison for future relicensings.

**3. The requestor, Sebago TU, is a non-governmental organization (NGO).**

**4. Background and Existing Information.** Existing information concerning the subject of the study proposal, and the need for additional information.

This is a small reach, 1.7 miles. The PAD documents the results of a survey conducted by Midwest Biological Institute reported in 2008 [PAD, page 5-124 and 125]. This is another of studies that has been requested but not received making provision of greater detail difficult.

**5. Nexus between Project operation and effects on the resource to be studied.**

The West Branch of the Penobscot River North Twin Dam to Quakish Lake provides riverine fish habitats that support fish populations, which may be affected by operations. Collection of baseline fisheries information will provide a better understanding of the potential effects of continued operation on resident fish species.

**6. Explain how the proposed study is consistent with generally accepted practice in the scientific community.**

Electrofishing is a standard, fish sampling methods for providing baseline fisheries data.

**7. Describe considerations of level of effort and cost, as applicable, and why proposed study alternatives would not be sufficient to meet the stated information needs.**

The level of effort should be consistent with that of past electrofishing studies conducted by MBI. The estimated cost for the baseline fisheries assemblage survey is approximately $5,000.

**Study Request: Lower Millinocket Stream and West Branch (Millinocket Tailrace to Dolby Pond) including Shad Pond Baseline Fisheries Assemblage Study**

**1. Study Goals and Objectives.**
Document the fisheries assemblage in the Project waters.

**2. Relevant resource management goals.** (Under §5.9(b)(3) If the requester is a not a resource agency, explain any relevant public Interest.)

Maine's rivers, great ponds and wildlife are, by law, public resources. Sebago Chapter members use the area for fishing and other recreational activities, and thus have a direct interest in the waters affected by project operations.

MDIFW manages the Lower Millinocket Stream and West Branch (Millinocket Tailrace to Dolby Pond) as a warm water fishery. The objective of the study is to document the existing fisheries assemblage and to collect information about the distribution and fish species present in the Project waters. Data collected will document the relative abundance and distribution of cold and warm water fish species present in the Project area, evaluate size class information (i.e., adult, juvenile, young-of-year), and species diversity.

Data obtained may also be used as a basis of comparison for future relicensings.

**3. The requestor, Sebago TU, is a non-governmental organization (NGO).**

**4. Background and Existing Information.** Existing information concerning the subject of the study proposal, and the need for additional information.

The PAD documents sampling conducted by the Midwest Biodiversity Institute (MBI) Study in 2004 on page 5-126. This study was not provided by the applicant making it difficult to provide details of how to repeat it. Sampling data is provided for Shad Pond but not the riverine sections. TU deems this adequate.

**5. Nexus between Project operation and effects on the resource to be studied.**

The Lower Millinocket Stream and West Branch (Millinocket Tailrace to Dolby Pond) including Shad Pond provide lacustrine and riverine fish habitats that support fish populations, which may be affected by operations. Collection of baseline fisheries information will provide a better understanding of the potential effects of continued operation on resident fish species.

**6. Explain how the proposed study is consistent with generally accepted practice in the scientific community.**

Gill netting is a standard, fish sampling method for providing baseline fisheries data.

**7. Describe considerations of level of effort and cost, as applicable, and why proposed study alternatives would not be sufficient to meet the stated information needs.**

The level of effort should be consistent with that of past electrofishing studies conducted by MBI. The estimated cost for the baseline fisheries assemblage survey is approximately $20,000.

### Study Request: West Branch of the Penobscot River Below Stone Dam Baseline Fisheries Assemblage Study

**1. Study Goals and Objectives.**
Document the fisheries assemblage in the Project waters.

**2. Relevant resource management goals.** (Under §5.9(b)(3) If the requester is a not a resource agency, explain any relevant public Interest.)

Maine's rivers, great ponds and wildlife are, by law, public resources. Sebago Chapter members use the area for fishing and other recreational activities, and thus have a direct interest in the waters affected by project operations.

The West Branch of the Penobscot River Below Stone Dam provides minimal fishing opportunity due to dewatering. The objective of the study is to document the existing fisheries assemblage and to collect information about the distribution and abundance of salmonids and other fish species present in the Project waters. Data collected will document the relative abundance and distribution of cold and warm water fish species present in the Project area, evaluate size class information (i.e., adult, juvenile, young-of-year), and species diversity.

Data obtained may also be used as a basis of comparison for future relicensings.

**3. The requestor, Sebago TU, is a non-governmental organization (NGO).**

**4. Background and Existing Information.** Existing information concerning the subject of the study proposal, and the need for additional information.

The PAD documents the results of the 2004 Midwest Biodiversity Institute (MBI) Study on page 5-131. Provision of the study would have enabled inclusion of additional detail in this study request.

**5. Nexus between Project operation and effects on the resource to be studied.**

The West Branch of the Penobscot River Below Stone Dam provides riverine fish habitat that support minimal warm water fish populations fish populations, which may be affected by operations. Collection of baseline fisheries information will provide a better understanding of the potential effects of continued operation on resident fish species.

**6. Explain how the proposed study is consistent with generally accepted practice in the scientific community.**

Electrofishing is a standard, fish sampling methods for providing baseline fisheries data.

**7. Describe considerations of level of effort and cost, as applicable, and why proposed study alternatives would not be sufficient to meet the stated information needs.**

The level of effort should be consistent with that of past electrofishing studies conducted by MBI. The estimated cost for the baseline fisheries assemblage survey is approximately $20,000.

Kimberly D. Bose, Secretary October 9, 2021

Federal Energy Regulatory Commission

888 First Street, NE

Washington, DC 20426

**Subject: Comments and Needed Studies Re; September 24, 2021 Filing Re: Ripogenus Hydroelectric Project (FERC No. 2572-133) Penobscot Mills Hydroelectric Project (FERC No. 2458-247) Supplemental Information – Source Information and Existing Studies**

**Dear Secretary Bose,**

**Via FERC E-filing**

**On September 30, 2021, I electronically filed comments on the Pre-Application Document (PAD) and Scoping Document 1 (SC1) for the now combined Ripogenus and Penobscot Mills Projects. As I noted, the Projects' impoundment and riverine reaches no longer support fish and aquatic invertebrate communities at the levels observed in the 1980s (cited in the 1992 license). As I wrote in my September 30. 2021 filing, I participated and authored many of the studies listed in the Licensee's September 24, 2021 filing. Due to an almost forty-year data gap and a major change in project operations, the 1980s studies are not relevant to existing peaking operations and flow regimes. The fisheries and aquatic communities need to be returned to the 1992 baseline established by the Environmental Impact Statement. In order to restore project fisheries and aquatic communities, a great deal of information needs to be collected. This is the responsivity of the licensee. I now offer my comments and recommendation for much needed studies.**

**Impoundments**

1) **Determine the loss of littoral acreage as it changes with impoundment elevations and time.**

2) **For the Ripogenus Impoundment, based on the results of Normandeau's 1980 survey, determine the change (if any) in the Ripogenus Impoundment plankton communities.**

3) **Determine the abundance, condition and angler utilization of impoundment (Ripogenus and North Twin) salmonid (including Lake whitefish in the Ripogenus Impoundment) and burbot (Lota lota) populations**

**Riverine reaches**

1) **The river including by-passed reaches are a public resource. The licensee should not be permitted to enjoy the financial gain of this resource without mitigation which compensates the resources beyond the modest tradeoffs allowed when the project's two mills supported 1400 jobs 30 years ago. The Licensee states no new fishery studies are needed without providing <u>current</u> supporting data e.g., recent creel survey, age-growth and survival information. How is it possible for the licensee to make and defend such a statement without**

**supporting documentation? FERC must require studies to determine the abundance, condition, growth and angler utilization of West Branch salmon populations in all river reaches within and below the project areas. The data should be broken out by wetted and by-passed river segments to allow analysis of mitigation opportunities.**

**1a) For the West Branch below McKay Station and extending to Debsconeag Falls, using radio tagging determine;**

**Any seasonal change in up or downstream salmon movement in response to peaking operations**

**AND**

**Any response, including lateral movement, to peaking flows that could cause changes in salmonid feeding behavior, survival or fishing opportunity**

**AND**

**Any post spawning/overwintering salmon mortalities resulting from historically low winter and early spring low-flow events.**

2) **Upper Gorge;**

   **Determine a suitable method of providing (July 1st – September 30th) flows cooler than those provided by surface flows passed through the Ripogenus Dam log sluice gate.**

   **Conduct a flow study an determine a suitable October 1st – June 30 environmental flow and confirm that the July 1st to September 30th flow continues to meet fisheries objectives.**

3) **Determine any change in smelt (Osmerus mordax) abundance ("drift") below McKay, North Twin, Dolby and Millinocket (formerly the Grinder Room) Stations. Duplication of GNP's weekly collections referenced in the Licensee's September 24, 2021 filing would be preferred.**

4) **Using Normandeau Associates 1981 marco-invertebrate methods (Surber, rock baskets) and collections sites, identify changes (species abundance and composition) in the aquatic insect communities.**

5) **For the West Branch below McKay Station, determine new minimum flow goals, including flows that protect the Holbrook Bypass Stream. This critical mitigation measure was actually dewatered a number of times in 2021.**

6) **Determine if Backchannel (the dewatered West Branch channel below Stone Dam) upstream fish passage is desired (there maybe a need to prevent exotic species introductions) or needed at Stone Dam.**

**Water management**

**Develop (from an independent peer reviewed source) a water management criteria that will ensure that (yet to be determined) minimum flows goals below Ripogenus Dam and McKay Station and downstream of North Twin Dam can be met. Any license must to be constructed to ensure full compliance. And emergency deviation should only be allowed after consultation with the Maine Department's of Environment Protection and Inland and Fisheries and Wildlife.**

**For all facilities, develop and implement state-of-the-art ramping rates that will protect aquatic insects and juvenile and adult salmonids**

**Angler access**

**Unfortunately, we live a period where industry and populations are threatened by persons whom would do harm to the American way of life. One of the results is the fencing off of a number project facilities that results in lost/reduced angler access and fishing opportunity. Fences at McKay and North Twin, Millinocket (formerly the Grinder Room) Stations limit angler access, and vehicle access to the Dolby tailrace is blocked and foot access difficult. Given that boat access is presently allowed to the (turbine) draft tubes, it seems reasonable to allow foot access to similar locations. The entire drainage is a public resource. Recreational opportunity should not be prohibited or inhibited by the licensee. Access is easy at many of the licensee's other projects in Maine including but not limited to Harris Dam and Station on the Kennebec, Welden Dam and Station and Milford Dam and Station on the main stem Penobscot. Why not all the West Branch dams and stations?**

**Develop a suitable website that provides both real time flow and elevation information as well access to archival information.**

**Maine Departments of Environmental Protection and Inland fisheries and Wildlife are the state agencies charged with responsibility for project resource protection and management. These two agencies must have full oversight in all studies and data analysis.**

**Thank you for the opportunity to comment and to purpose necessary studies**

**RE: Penobscot Mills (P-2458-247) and Ripogenus (P- 2572-133) Notice of Intent, Pre-application document, Scoping document #1 and study requests**

Dear Secretary Bose,

The Penobscot Indian Nation (PIN) has reviewed the Notice of Intent (NOI), Scoping Document #1 (SD1), and the Pre-Application Document (PAD) filed with the Federal Energy Regulatory Commission (FERC) for the Penobscot Mills and Ripogenus Projects, located on the West Branch of the Penobscot River in Maine and has drafted comments accordingly. The PIN is unable to completely assess the cultural, biological and socioeconomic impacts of relicensing of the projects, and to draft appropriate study requests, due to the lack of information and extensive exclusionary detailing perpetuated by the licensee in the PAD, and NOI. The PIN submitted an Extension of Time request to the FERC on 9/16/21 for an additional 90 days to review the currently unavailable information not included in the PAD and NOI and to prepare study requests. However, on 9/28/21, the FERC denied the request. The FERC went on to request additional data, similar to the multiple agency requests, on 10/8/21.

**Agency Support**

The PIN would like to express its support for the comments and all study requests submitted by our partner agencies, the US Fish and Wildlife Service (USFWS), National Ocean and Atmospheric Administration (NOAA) the Maine Dept. of Marine Resources (MDMR), and the Maine Dept. of Environmental protection (MeDEP). The PIN works collaboratively with these agencies and designs our comments and study requests accordingly.

**Tribal History and Federal Lands**

The Penobscot Nation has inhabited the Penobscot River, including the West and East Branches, from time immemorial. This is the Nation's aboriginal domain. The Nation has never ceded its related aboriginal title to the River and its branches in any treaty and Congress has never extinguished that aboriginal title. It is the Nation's position that

Ripogenus and the Penobscot Mills Projects, located on the West Branch of the Penobscot River, occupy federal lands, the Penobscot Reservation. To the extent that the Scoping Documents states otherwise, the Nation disagrees.

**Back Channel**

The PAD and supporting documents refer to the West Branch of the Penobscot River below Stone Dam as "The Back Channel". This is terminology is offensive to the PIN and is believed to have been adopted by the previous licensee to diminish the importance of the river channel and to create public confusion as to what section of the river is really being talked about. The PIN request that this nomenclature cease from being used in this proceeding.

**Tribal Needs:**

The FERC, on July 23, 2003, issued a *Policy Statement on Consultation with Indian Tribes in Commission Proceedings* (18 CFR Part 2, Docket No. PL03-4-000; Order No. 635) In that statement, the FERC created a Tribal liaison position to help Tribes actively engage in FERC matters. The PIN would like to express its strong desire to consult with the Tribal liaison at the FERC as soon as possible, such that Tribal issues and concerns can be articulated to the FERC within its' process guidelines and obligations. The PIN had no knowledge that such a position even existed, but looks forward to consulting with the FERC liaison about this important relicensing and others in the Penobscot River drainage.

Additionally, the PIN asked the FERC about the establishment of baseline conditions at the project for environmental review and for the analysis of alternatives at the projects. Specifically the PIN asked during the Scoping meeting held on 9/9/21 about how the 2018 American Rivers court case, which vacated Alabama Power's project license and remanded the matter back to FERC for further consideration, would affect the FERC process for the current relicensing. The FERC responded in their letter dated 9/28/21 that the case as ongoing but documents had been issued since the verdict and the FERC provided a link to the updated draft supplemental environmental impact statement (DSEIS) for the Coosa River Hydroelectric project. The DSEIS was an excellent read, however the PIN was not able to find any information as to how the DSIES considered the historic condition as the baseline condition. The PIN would ask that the FERC Tribal liaison, or other FERC staff, work with the PIN to understand this case, the connections to the cumulative impacts of the projects in this relicensing and the use of the historic, pre-dam conditions for analysis by the FERC.

**Environmental Justice**

The PIN also has concerns of Environmental Justice surround the continued operation of the projects, as they may disproportionately affect minority and low-income people living in the region. The PIN asks that FERC staff provide guidance to the stakeholder as to the environmental justice concerns at the project, any recent changes in the FERC NEPA analysis that may or may not include sections on environmental justice, and how they could be related to these projects.

**Socioeconomic Working Group**

The Klamath Hydroelectric project (P-2082), during relicensing in the early 2000's, created a Socioeconomic Working Group during the Scoping process to assess the socioeconomic impacts of the projects. The working group drafted a study plan together and submitted it for review in 2002. The group then recommended the study be conducted in two phases. The Final Technical report was released in February of 2004. The PIN request that the FERC provide a pathway forward to establishing such a working group in this proceeding. The PIN finds itself without the technical expertise to comprehensively develop a study plan to assess the socioeconomic conditions in the region. The PIN therefore believes a Socioeconomic Working group should be established immediately. Members could include a variety of stakeholder from the Millinocket region, Penobscot and Piscataquis counties and subject matter experts available at the University of Maine in Orono. The FERC is well versed in the proper creation of such a group and process, and the PIN will rely upon the FERC and its Tribal Liaison to help promote and execute this most important matter.

**NOI Comments**

Ripogenus (P-2572)

**Section 8V.** The PIN is an affected Native American Tribe with Tribal lands and Treaty reserved sustenance fishing rights negatively affected by continued project operations.

**PAD Comments**

**Section 5.1.2.**

The description of the uses of the Penobscot watershed and surrounding area of the projects focuses on timber, pulp and paper, and hydro development. It falls short in describing other significant uses of the watershed, especially the cultural uses by Penobscot Nation. The licensee narrative creates a false illusion that industrial/logging are all that have ever existed or are important.

**Section 5.1.3.**

This section contains no mention of cultural uses by the tribe. Tribal cultural uses are not adequately explained and should not fall under recreational uses. Many areas of the PAD makes make no mention of the long history of the Penobscot Nation throughout the project areas. This history is clearly demonstrated by the various place names which are Penobscot/Wabanaki : (Pemadumcook -"lake with gravelly or sandy bottom or sand bars"; Millinocket – "admirable place"; Ambajesus – "eddy place; Katahdin; Chesuncook; Penobscot.)

*Downstream uses and aquatic life* – The applicant states that the flows from the projects are beneficial to downstream aquatic habitat and spawning areas within the West Branch and mainstem. However, there is no documents, studies, references, etc that are provided to support these statements. This should be quantified and documented. Furthermore, while the Penobscot Mills dams are operated "run-of-river" they are certainly affected by the upstream Ripogenus Project flows. What is the cumulative effects of both projects within their project areas as well as downstream?

**Section 5.3.9.**

**Water Quality** (general comments)

-*Existing water quality of Ripogenus*.

The data provided for the previous license is outdated (1986-88) and needs to be redone to demonstrate attainment with water quality standards. The applicant states that the Watyer quality (WQ) monitoring demonstrated there was no degradation of WQ due to the operation of the Ripogenus Project. This is misleading. Meeting water quality standards does not mean there is no degradation, just that criteria for that class are met. The licensee also makes unsupported claims that the operation of the Ripogenus dam limits the severity of a dissolved oxygen deficit in the hypolimnion and enhances removal of nutrients from the impoundment and provides valuable food resource to the West Branch.

-*Existing water quality of Penobscot Mills project*

Much of the water quality data referenced in the PAD is outdated and needs to be repeated. While the impoundments met the DO criteria for class C at that time, these waters have been upgraded to Class B since the last relicensing. The old data provided would not meet class B criteria. New data is needed to demonstrate whether the waters will attain class B criteria.

The applicant makes a simple statement that Lower Dolby Pond had elevated chlorophyll-a and turbidity and that "good water quality conditions are due to sustained and consistent flows provided by the storage withdrawals". Dolby has a long history of poor water quality and significant algal blooms, that are well documented by PIN and ME DEP. The 2016 Integrated Report Table 5.3-9 on (pg 5-69) indicates that water quality in Dolby Pond was not meeting water quality standards due to DO and nutrient issues. While the primary cause of the non-attainment was from phosphorous loading from an upstream discharge, the impoundment created by the Dolby Dam is a contributing factor

as it serves as a "cooker" by providing ideal conditions for blooms to develop. The dam also further exacerbates the blooms by allowing phosphorous to settle into sediments within the impoundment which become available during anoxic conditions when the impoundment thermally stratifies. These nutrient rich sediments will continue to contribute to phosphorous loading and potential algal blooms even after the discharge levels are reduced or cease.

-*West Branch Penobscot Below Stone Dam* –Table 5.3-9 (pg 5-69) lists river reaches in the Penobscot Mills Project that are listed in Category 4 of Maine's 2016 Integrated Report. The report lists the 5.1 mile segment of the West Branch below the outlet of Quakish Lake to the confluence of Millinocket Stream as being impaired and not meeting water quality standards due to flow diversion modifications for the Quakish Lake/Stone Dam. While DEP waived CWA Section 401 certification during the last relicensing of the project, this shows that the project is not meeting water quality standards and will continue to not meet standards under the current operation.

Table 6.1-3 list comments from GLHA regarding potential effects and resource issues associated with the projects. PIN contends that these responses are inadequate and misleading.

- Some of the comments state that the West Branch below Stone Dam is difficult to access and that use of the area is minimal suggesting there is no need to study the area. In other sections of the PAD (Article 412) the applicant reports on the enhancements they have made including seeded and maintained access roads to the area and creation of a wildlife management area. PIN staff have travelled by vehicle during summer 2021 to this area without any difficulty. Their statement that "angler use is minimal" is the result of poor aquatic habitat quality and insufficient flows to support a desirable fishery. Restoring flows to this river segment would improve the fishery.
- Potential effect on RTE species – GLHA lists the presence of several RTE species identified by ME DIFW in the project areas and comments that there are not any anticipated adverse effects on the species because there are no proposed operational changes. The mere presence of these RTE species is not evidence that the species are not detrimentally harmed by the operation of the dams. The licensee should provide additional data about the health of the populations, whether they are sustainable and at what levels under the current flow regimes, and whether they would be enhanced by alternative flow regimes.

**<u>Toxic Metals</u>**

The PAD is misleading on the topic of toxic metals, particularly mercury. The licensee states that they found no difference in mercury levels in sediments from the impoundments with drawdowns vs control lakes and that FERC concluded no evidence of project operations leading to increased mercury levels. However, the conclusion of many of the agencies on the Article 404 and 405 studies from the previous license was that there appears to be a relationship between drawdowns and mercury levels. The agencies generally agreed that the 404 and 405 study requirements were met, but they recommended that the role the operation of the dams plays on mercury levels needs additional study, including mercury levels in loons (add references including meeting notes and letters from the agencies). The licensee was very selective about what they chose to summarize from the Haines and Norton 1999 study and only included bulleted statements from the study that support their claim that the project flow regime does not affect mercury levels, and do not include any results or statements from the study that suggest otherwise. We request that FERC require the applicant to conduct additional/continued studies on toxic metals in fish, sediments, water, and piscivorous birds to demonstrate that the dams are not contributing to the unsafe levels of mercury that require issuance of fish consumption advisories. We also think that routine testing of fish from project waters should be required of the applicant to advise recreational and sustenance anglers about the safety of consuming fish from these waters.

*Loon and eagle productivity from project areas* – The PAD references studies about nesting productivity of eagles and loons from the project waters, but only addresses the availability of nesting sites. Elevated levels of mercury in the foods of loons and eagles are known to have a detrimental effect on the productivity of these piscivorous birds. Burgess and Meyer (2008) found that maximum observed loon productivity dropped 50% when fish Hg levels were 0.21 ug/g (wet wt.), and failed completely when fish Hg concentrations were 0.41 ug/g. The PAD indicates that mercury levels in salmonid species monitored in 2015 exceeded the Maine DHHS guidelines for consumption but did not provide any data on fish tissue concentrations. The licensee should provide information not only about availability

of nest sites, but also about the number of chicks that hatch, survival of the chicks, and whether the mercury concentrations in the food base from the project waters is at a level that could impair reproduction.

**Shortcomings of Proposed Studies**

Table 6.2-2 provides details of proposed studies by the applicant which need to be expanded.

1. Water Quality Study - This water quality work should not be limited to just the deep hole in riverine impoundments such as Dolby. Additional sites should be included to properly characterize water quality conditions throughout the impoundment, including the inlet and the main channel upstream of the dams. Water quality standards are more easily met at the deep hole because attainment cannot be measured below the point of thermal stratification. Furthermore, 38 MRSA 464 13C states that where mixing is inhibited due to natural topographical features in an existing riverine impoundment, compliance with numeric dissolved oxygen criteria may not be measured within that portion of the impoundment that is topographically isolated. Such natural topographic features may include, but not be limited to, natural deep holes or river bottom sills. Hence, if the licensee only takes measurements in the deep hole, they will argue that they meet WQS when there may be other more representative areas of the impoundment that are not attaining standards.
2. Macroinvertebrate Survey - This survey must include macroinvertebrate sampling in the West Branch downstream of the Stone Dam (Back Channel). The survey plan does not list this area as one of the proposed sites. The purpose of this work is to determine whether aquatic life criteria are being attained. Without benthic macroinvertebrate data from this site ME DEP will be unable to determine whether aquatic life criteria are being met.
3. Recreation and Land Management Inventory - This plan should include removal or marking of navigational hazards, particularly in Dolby Pond. There are many deadheads and standing trees that are an impediment to recreational/navigation in this area.

PIN Water Resources Program also believes that the licensee should be doing a study to determine the role that the Dolby dam has on dissolved oxygen levels, nutrients, and algae in the impoundment and downstream river. Dolby has a long history of episodic cyanobacteria blooms. The impoundment creates an environment that allows the algae to flourish when the right conditions are present. We are concerned with the phosphorous that has deposited in the sediments in the anoxic zone and becomes available. This situation would not exist if the dam was not present.

**Section 5.1**

> "Populations in the towns of Millinocket and East Millinocket are expected to continue to decrease by approximately 44 percent between 1970 and 2036, compared to an expected increase in population by 35 percent at the state level." (EMDC 2020)
>
> "The mean household income in 2019 was $40,890 for Piscataquis County and $50,808 for Penobscot County, compared to $57,918 for the state in 2019." (USCB 2019)
>
> "The estimated 2019 population of Piscataquis County was 16,785 people, reflecting a 4.3 percent decrease over the nine-year period between 2010 and 2019. The 2010 census reported that Penobscot County has a population of 153,923. The estimated 2019 population of Penobscot County was 152,148 people, reflecting a 1.2 percent decrease over the nine-year period between 2010 and 2019." (U.S. Census Bureau [USCB] 2019)

These quotes from Section 5.1 are insufficient to describe and evaluate the socioeconomic resources of the region. However, they do paint a picture of economic distress, with a shrinking population. This condition is inconsistent with the entire State of Maine and goes to elucidate the fact that the Millinocket region has suffered tremendous socioeconomic distress and crisis since the mills have been closed during the last licensing period. The mills ran on electric power generated by the projects. Now the energy goes into the grid without supporting the local community. The past dedication of public resources was done with support for the local mills and community. The entire situation has changed. A robust socioeconomic study must be conducted.

There is a lack of information concerning the construction of the projects, the past relicensing process, the Great Northern Paper company mills in Millinocket and East Millinocket, Maine, and the massive changes in the socioeconomic conditions experienced by the local community and the state of Maine since the last relicensing.

Great Northern Paper (GNP) Company was founded in the late 1800's. The company created the "Magic City" in the north Maine woods where no organized town had been before. GNP contracted for homes, tenements and even a hotel to be built in the city to supply housing for workers at the mills. (http://greatnorthernpaperhistory.com/the-paper-giant/millinocket-grows.html) GNP built and maintained the Penobscot Mills and Ripogenus projects specifically to provide energy to their mills and to provide an economic advantage over its competitors. It was the first paper mill to have an electrical generation and distribution facility built into the plant. (https://en.wikipedia.org/wiki/Great_Northern_Paper_Company) In the 1940's the timberland owned by GNP had grown to over 5 million acres. In 1977 GNP was still Maine's second largest private employer after Bath Iron Works. At one time GNP's was the nation's largest industrial hydro-electric system, producing enough power to electrify a city of 450,000 or, comparably, almost half the homes in Maine. (https://damnyankee.com/great-northern-paper)

The history of GNP in Maine, its control of the local socioeconomic conditions, and the contentious nature of the relicensing in the late 1980's and early 1990's is not mentioned in the PAD. However, it is this history, and the massive changes that have happened in the Millinocket region since the last relicensing, that makes these matters of paramount importance to the FERC Scoping process where socioeconomic conditions in the area have to be considered in the upcoming environmental analysis inherent in the FERC process.

The last relicensing for these projects was historical in its size, scope and contentiousness. Numerous state legislators made comments during the proceedings, asking the FERC to not impose economic hardships on GNP for environmental concerns, as these would have potentially effected GNP's ability to be competitive and maintain the high paying jobs for the local economy. In a letter dated 4/22/1993 the Maine state commissioner for the MeDEP waived the Dept's authority to certify Water Quality standards (order #L-17166-32-A-N) for the West Branch below the Stone Dam. This waiver was based on political pressure and the issue of economics for the projects and recommended minumu flows in the area. Additionally, the FERC was sued by the Conservation Law Foundation after the license orders were issued. (United States Court of Appeals for the District of Columbia circuit) Argued April 20, 2000, Decided June 23, 2000. No. 99-1035)

The complexity and contentiousness of the last relicensing should be included in any project history by the licensee or the FERC. Perhaps there are lessons to be learned from these past events that will eliminate the need for extensive and expensive legal action to ensue during or after this relicensing proceeding. However, with the incomplete background information within the licensee produced PAD, the FERC and all other stakeholders will find it extremely difficult to assess the socioeconomic concerns of the region that have dramatically changed since the licensee purchased the projects and closed down the paper mills.

**SD1 Comments-**

**Section 1.0.**

The section explains that the projects do not occupy federal lands. The Penobscot Nation has inhabited the Penobscot River, including the West and East Branches, from time immemorial. This is the Nation's aboriginal domain. The Nation has never ceded its related aboriginal title to the River and its branches in any treaty and Congress has never extinguished that aboriginal title. It is the Nation's position that Ripogenus and the Penobscot Mills Projects, located

on the West Branch of the Penobscot River, occupy federal lands, the Penobscot Reservation. To the extent that the Scoping Documents states otherwise, the Nation disagrees.

**Section 3.4.**

SD1 indicates that project decommissioning is not a reasonable alternative to relicensing the project with appropriate environmental measures. No studies have been conducted of any kind in the area to assess the negative affect of modern project operations on the natural or human environment. The record of resource issues to date is incomplete, as a complete socioeconomic study has not been conducted. This study will be needed for the NEPA analysis and currently does not exist. The socioeconomic resource concerns investigated and explained in such a report may lead the FERC to the decision to consider decommissioning and removal for all the projects during its analysis.

**Section 4.1.**

The PIN would lie to point out that there are potentially many other resources that are cumulatively effected by the project and its existence over decades. The socioeconomic conditions of the local areas have changed dramatically since the last relicensing. These resource issues should be added to the list in Section 4.1.

**Section 4.1.6**.

There is no mention of PIN cultural resource concerns based on current operations, which have no connection to the National Register of Historic places. There is also no mention of other cultural connections from the local community and the State of Maine.

The PIN appreciates the careful consideration of these comments and study request by the FERC. If there are any questions for the PIN about these comments, please send them along at your convenience. As issues come to light that were not previously described by the PAD, SD1 or the PIN, the Tribe will alert the FERC to these issues accordingly.

Sincerely,

Daniel McCaw

Fisheries Program Manager
Penobscot Indian Nation
12 Wabanaki Way,
Indian Island, ME 04469

**PIN study request-**

**Socioeconomics Study**

*§5.9(b)(1) –* ***Describe the goals and objectives of each study proposal and the information to be obtained.***

The goals of the study would be to describe the existing socioeconomic environment in the study area, including population, housing, economic development, public services, local energy production, State of Maine statues for energy production in the future, fiscal conditions, and infrastructure.

The study would describe socioeconomic resource trends under the existing condition, summarize the existing condition of the recreation resources in the study area and describe the current Project and social and environmental measures as they relate to the socioeconomic factors.

The study would also describe changes in employment or income associated with modifications to recreational potential for the river in existing and pre-dam conditions.

The study would describe the current socioeconomic condition of the Maine Tribes and identify socioeconomic issues and concerns.

The study would also serve as a source of information in considering other options for the projects, to include decommissioning and removal.

To understand incremental Project effects on socioeconomic resources, it is important first to characterize the existing population demographics, local human resources and public services, the local and tribal economy, as well as pertinent trends in such factors. It will be necessary to identify the study area in terms of the geographic extent of the potential incremental Project's sphere of influence on the socioeconomic condition as well as to identify likely differences across regions in the types of socioeconomic factor effects. The existing information is used to identify current socioeconomic conditions and expected trends in the study area. This is one of many reasons a Working group should be established: to define these parameters for the study.

The results of this study will provide information to satisfy FERC license application requirements specific to Project-related effects on the socioeconomic environment as specified in the applicable sections of 18 CFR Parts 4 and 16.

*§5.9(b)(2) –* ***If applicable, explain the relevant resource management goals of the agencies or Indian tribes with jurisdiction over the resource to be studied.***

Not applicable.

*§5.9(b)(3) –* ***If the requester is not a resource agency, explain any relevant public interest considerations in regard to the proposed study.***

The requestor is a Federally-Recognized Indian Tribe, the Penobscot Indian Nation.

*§5.9(b)(4) –* ***Describe the existing information concerning the subject of the study proposal, and the need for additional information.***

The PIN knows of no such study or data available, with the exception of the population and census data contained within the PAD.

*§5.9(b)(7) –* ***Describe considerations of level of effort and cost, as applicable, and why any proposed alternative studies would not be sufficient to meet the stated information needs.***

Cost and effort would depend on the number of alternatives included in the analysis and the amount of existing information. We anticipate that most or all of the information needed for this analysis already exists, however the information would need to be analyzed and findings to be drafted. A potential cost of $20,000 to $40,000 may be reasonable for such an extensive analysis. This study will require several months to two years of effort to complete. The licensee did not propose any alternative studies.

October 14, 2021

**FERC Project 2572**
**Article 402**

Kimberly D. Bose, Secretary
Federal Energy Regulatory Commission
888 First Street, N.E.
Washington, DC 20426

***Electronically Filed***

**Subject: Ripogenus Project, FERC No. 2572; Trout Unlimited Minimum Flow Complaint**

Dear Secretary Bose:

Great Lakes Hydro America, LLC (GLHA), licensee for the Ripogenus Project located on the West Branch of the Penobscot River in Maine, submits this letter in reply to Commission correspondence dated October 4, 2021, in which the Commission requests additional information regarding a complaint filed on September 21, 2021 by Mr. Stephen Heinz, writing on behalf of the Maine Council of Trout Unlimited (TU), that alleges two deviations from minimum flow requirements at the Project. The Commission requests that GLHA file a response to these allegations within 15 days (i.e., by October 19th) that includes:

> *(1) a description of your required flows on August 30 and September 16, 2021, based on the date, time and hydrologic year type; (2) gage data and/or project operational data indicating the actual flows prior, during, and after the alleged deviation; and (3) a description of any operational changes for August 30 and September 16, 2021.*

**August 30, 2021 low flow event**

On August 30, 2021, McKay Station (part of the Ripogenus Project) tripped offline at 12:05 pm as a result of thunderstorms in the area. The 400 cfs minimum outage flow was restored to the river within 13 minutes via the station's minimum flow system, and then the normal 2,000 cfs whitewater recreation minimum flow was restored within approximately 3.5 hours. A courtesy notification of this event was distributed to resource agencies on August 31, 2021.

> Required flows – between May 1st and September 15th, Article 402 of the Ripogenus Project license requires that minimum whitewater recreation flows of between 2,000 and 2,300 cfs be released from the Project between 0830 and 1700 hrs. on a daily basis. In a "dry" hydrologic year (such as 2021), the required minimum flows are 2,200 cfs on Saturdays and Sundays, 2,000 cfs on Mondays and Fridays, and 1,800 cfs on Tuesdays through Thursdays.
>
> During other hours of the day outside of the whitewater release time period (i.e., 1700 to 0830 hrs.), Article 402 requires a minimum flow of 1,000 cfs from June 8th through October 14th. Additionally, Article 402 allows reduced "outage" minimum flows of 400 cfs when generating unit failures occur at McKay Station, "*with scheduled minimum flows to be resumed as quickly and practically as possible by releases from Ripogenus Dam if necessary, but in no event in more than three days following the initial outage*".

Finally, Article 402 states that "*These specified minimum flows shall be the minimum flows for each hourly period (measured on the basis of an hourly average)*".

Since August 30th was a Monday and 2021 is a "dry" hydrologic year, Article 402 required that a minimum whitewater recreation flow of 2,000 cfs be released during the 0830 to 1700 hr. time period when the station trip occurred.

Operational data – the attached charts show Ripogenus Project outflows prior to, during, and after the August 30 low flow event and alleged license deviation.

Operational changes – On the afternoon of August 30, 2021, several hydro stations on the West Branch of the Penobscot River tripped offline during and after thunderstorm activity, including McKay Station at 12:05 pm. An investigation determined that a damaged lightning arrestor caused the outage at McKay Station. The minimum outage flow was restored to the river within 13 minutes via the station's minimum flow system (which automatically provides an emergency outage flow of more than 400 cfs), and then the 2,000 cfs whitewater recreation minimum flow was restored by 3:30 pm. The Ripogenus outflow dropped to a low of 109 cfs during the event, while the lowest hourly average outflow was 640 cfs.

Summary – although GLHA provided a courtesy notification regarding the August 30 low flow event to resource agencies (see attached), GLHA determined that the event was not reportable to the Commission as an excursion from license requirements, since the hourly average outflow did not drop below the emergency outage flow of 400 cfs. Further, the automatic minimum flow system at McKay Station functioned as designed during the event, and GLHA was able to restore river flows in a timely fashion.

**September 16, 2021 low flow event**

On September 16, 2021, McKay Station tripped offline due to a Versant Power (local utility) line disturbance. Flow was restored to the river within 5 minutes via the station's minimum flow system, and then the normal 1,000 cfs minimum flow was restored within approximately 2.5 hours. A courtesy notification regarding this event was distributed to resource agencies on September 16, 2021.

Required flows – from September 16th through October 14th, Article 402 requires a minimum flow of 1,000 cfs, except higher minimum whitewater recreation flows are required on weekends from 0830 – 1700 hrs. through October 1st.

As indicated above for the August 30th event, Article 402 allows reduced minimum "outage" flows of 400 cfs during generating unit failures at McKay Station, and it specifies that an hourly average be used as a basis for license compliance.

Since September 16th was a Thursday, whitewater recreation flows were not required that day, and only the minimum flow was being conveyed at the time of the station trip.

Operational data - the attached chart shows Ripogenus Project outflows prior to, during, and after the September 16th low flow event and alleged license deviation.

Operational changes – at 7:31 am on September 16, 2021, all of GLHA's hydro stations on the Upper Penobscot (McKay; North Twin; Millinocket; Dolby; East Millinocket; Weldon) tripped offline due to a local utility (Versant Power) line disturbance. At McKay Station, the 400 cfs emergency outage flow was restored to the river within 5 minutes via the station's

minimum flow system, and then the 1,000 cfs minimum flow was restored by 9:58 am. The Ripogenus outflow dropped to a low of 118 cfs during this event, while the lowest hourly average outflow was 508 cfs.

Summary – as with the August 30 low flow event, a courtesy notification regarding the September 16th low flow event at Ripogenus was provided to resource agencies (see attached). However, GLHA determined that the event was not reportable to the Commission as an excursion from license requirements, since the hourly average outflow did not drop below the emergency outage flow of 400 cfs. Further, the automatic minimum flow system at McKay Station functioned as designed during the event, and GLHA was able to restore river flows in a timely fashion.

In summary, the two events detailed in TU's complaint were (1) created by unforeseeable events beyond GLHA's control; (2) corrected within 13 and 5 minutes, respectively; (3) resulted in minimum flow reductions too minimal and transitory to be considered license violations; and (4) nonetheless promptly reported as a courtesy to the relevant resource agencies.

The Commission's October 4th letter also requests that GLHA provide (1) any comments received from resource agencies or other interested parties regarding the flows on these dates, and GLHA's response, and (2) the maximum ramping rates that occurred on August 30 and September 16, 2021. GLHA received no comments from the resource agencies in reply to GLHA's courtesy notifications regarding the August 30 and September 16 low flow events, and no comments or questions were received from any other stakeholders (including TU). In addition, the Ripogenus FERC license does not require flow ramping, so minimum flows were re-established as quickly as possible (consistent with the Article 402 requirement to resume scheduled minimum flows *"as quickly and practically as possible")* after each low flow event as shown in the attached graphs.

Please e-mail me at kevin.bernier@brookfieldrenewable.com or call me at (207) 951-5006 if you have any questions or need additional information.

Sincerely,

Kevin Bernier

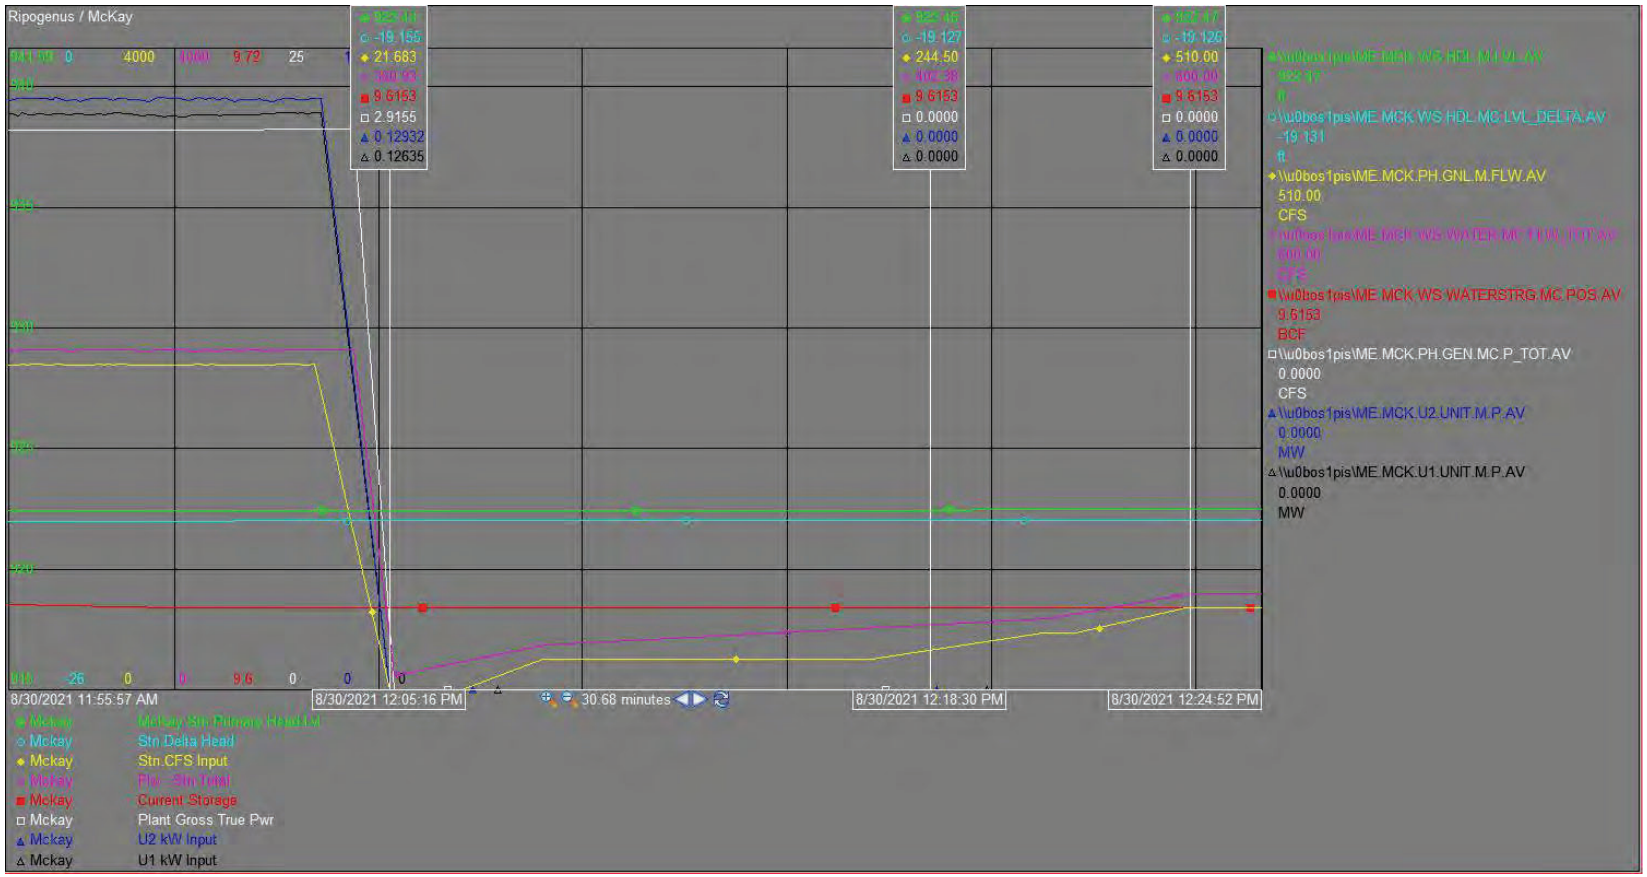
| **Subject:** | Penobscot station trips |
| **Date:** | Tuesday, August 31, 2021 3:22:00 PM |
| **Attachments:** | image001.gif |

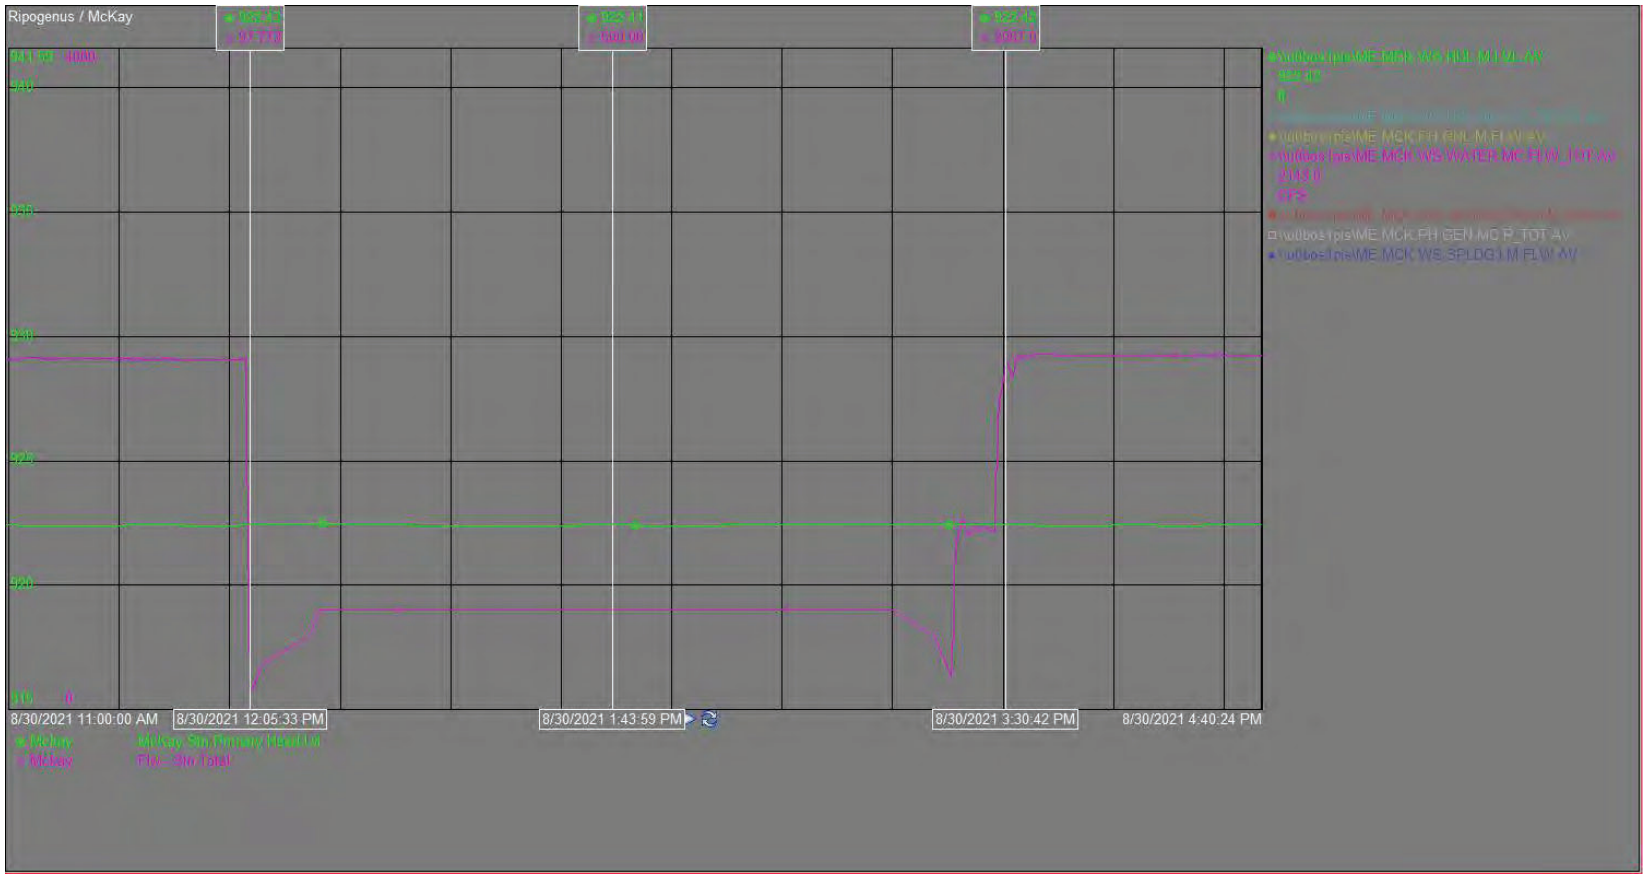
The North Twin and Millinocket hydro stations (both part of the Penobscot Mills Project) tripped offline during yesterday afternoon's thunderstorms when a breaker tripped. Following a downstream public safety check and activation of a siren alarm, system operators deflated the inflatable flashboard system at Stone Dam, thereby re-establishing the required 2,000 cfs minimum flow at Millinocket. Outflow from the Millinocket Development dropped to a low of about 175 cfs during this approximate 14-minute flow interruption.

Article 403 of the Penobscot Mills Project license requires in part that:

> *"The licensee shall operate the Millinocket, Dolby, and East Millinocket developments in a run-of-river mode while providing an instantaneous minimum flow of 2,000 cubic feet per second (cfs) to the West Branch of the Penobscot River at Millinocket, for the protection of water quality and aquatic habitat in the Penobscot River."*



Just so you know, McKay Station (part of the Ripogenus Project) also experienced two brief station trips yesterday afternoon during the thunderstorms; however, flow was restored to the river within 15 minutes after each event via either the station's minimum flow system or by restarting a unit. The McKay Station trips are not reportable, since there was no excursion of the hourly average minimum flow requirement.



Great Lakes Hydro America, LLC is still investigating the definitive causes for these station trips, but at this point they appear to be weather-related. I will copy you on the final report to FERC, but in the meantime, please let me know if you have any questions or concerns.

| **Subject:** | Upper Penobscot system wide outage |
| **Date:** | Thursday, September 16, 2021 8:08:00 PM |
| **Attachments:** | ~~image002.gif~~ |

This morning at 07:31 hrs, all of Brookfield's hydro stations on the Upper Penobscot (McKay; North Twin; Millinocket; Dolby; East Millinocket; Medway; Weldon) tripped offline due to a Versant Power line disturbance. Brookfield crews have been busy all day getting the stations back online and restoring river flows as soon as practicable after making public safety checks downstream. These station trips caused disruptions in run-of-river flows at the Medway Project (FERC No. 2666) and at the Millinocket, Dolby, and East Millinocket Developments (Penobscot Mills Project, FERC No. 2458). The trip of the Millinocket Hydro Station also resulted in an estimated 15-minute deviation from that Development's 2,000 minimum flow requirement, while the trip of Weldon Station resulted in an approximate 42 minute deviation from the Mattaceunk Project's 1,674 cfs minimum flow condition. As of 13:50 hrs this afternoon, all of the stations are back online, and normal operations have resumed.

Article 403 of the Penobscot Mills license states in part that:

> "*The licensee shall operate the Millinocket, Dolby, and East Millinocket developments in a run-of-river mode while providing an instantaneous minimum flow of 2,000 cubic feet per second (cfs) to the West Branch of the Penobscot River at Millinocket, for the protection of water quality and aquatic habitat in the Penobscot River. The licensee shall at all times act to minimize the fluctuation of the reservoir surface elevations by maintaining a discharge from each of these developments so that, at any point in time, flows, as measured immediately downstream from the tailraces of the developments, approximate the sum of the inflows to the project reservoir. Run-of-river operation or minimum flows may be temporarily modified if required by operating emergencies beyond the control of the licensee, and for short periods upon mutual agreement between the licensee, the U.S. Fish and Wildlife Service, and the Maine DEP. If the run-of-river operation or minimum flow is so modified, the licensee shall notify the Commission as soon as possible, but no later than 10 days after each such incident*."

Article 402 of the Medway Project license (as amended on April 18, 2005) states:

> "*The licensee shall operate the project in a run-of-river mode to protect aquatic life and water quality in the West Branch Penobscot River. The licensee shall at all times act to minimize reservoir surface elevation fluctuation by maintaining project discharge so that, at any point in time, flows immediately downstream from the project dam approximate flows into the project reservoir. The licensee shall maintain an impoundment surface elevation*

*within six inches of 260.3 feet above mean sea level (msl) except during emergency, maintenance, and high or low flow events beyond the licensee's control, following flashboard failures. Following flashboard failures, the licensee shall maintain the impoundment level within six inches of the spillway crest and shall replace the flashboards as soon as safely possible.*

*Run-of-river operations may also be modified for short periods upon mutual agreement between the licensee and the Maine Department of Environmental Protection (DEP). The licensee shall notify the Commission as soon as possible, but no later than 10 days after each incident resulting in a change in run-of-river conditions as specified above*."

Article 403 of the Mattaceunk Project license in part states:

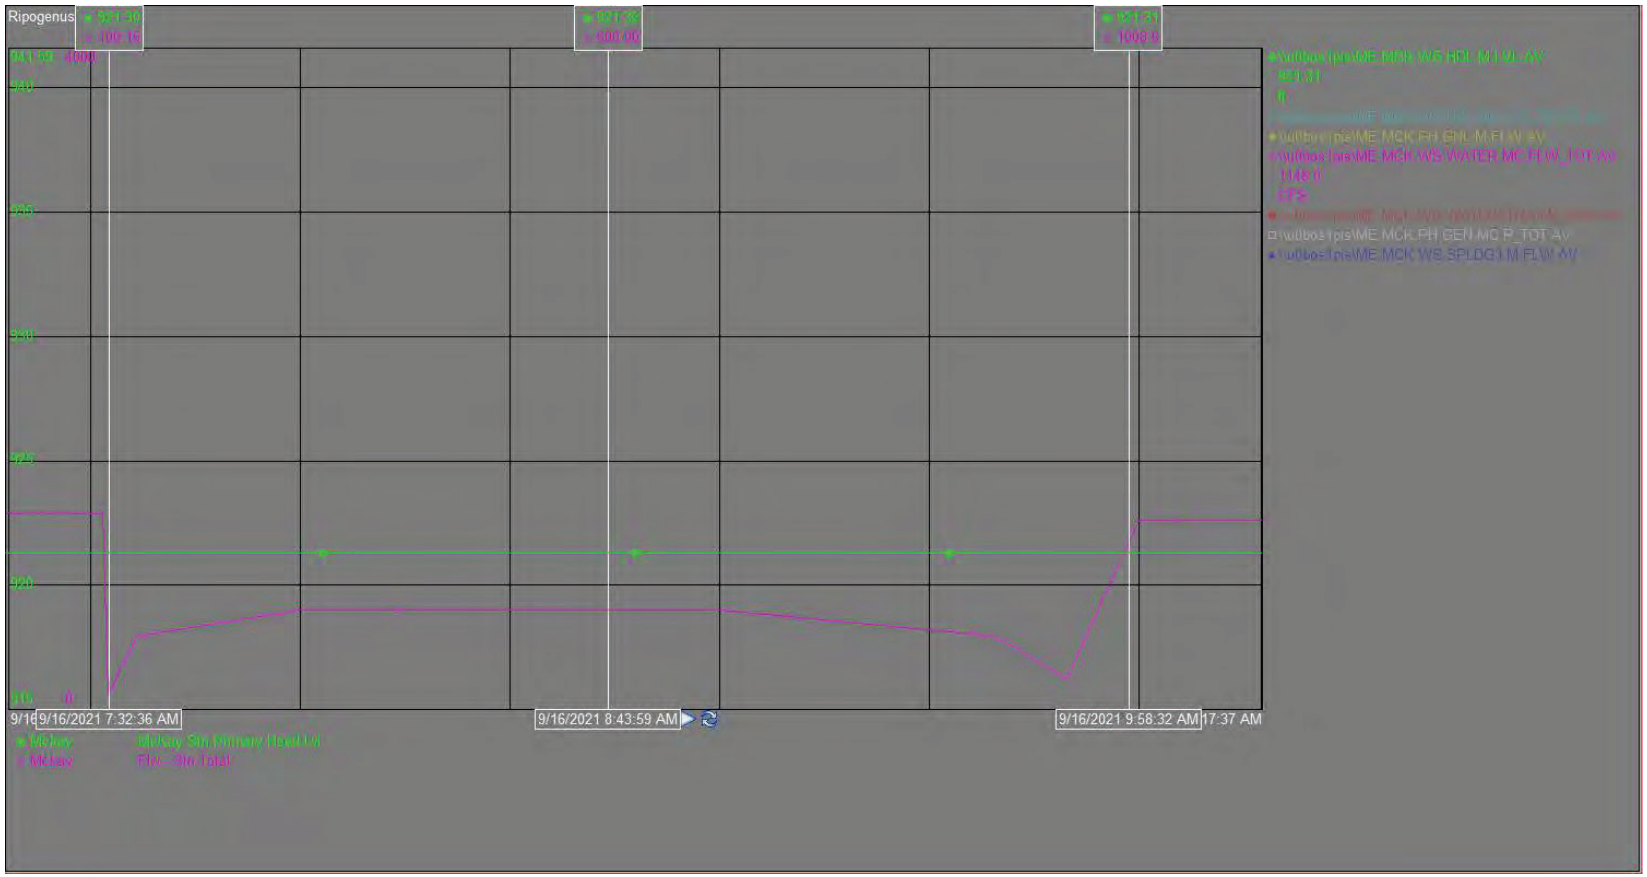
"*In addition to implementing the impoundment level requirements of Maine Department of Environmental Protection's (Maine DEP) condition A (Appendix A) and minimum flow requirements of Maine DEP's condition B (Appendix A), the licensee must operate the Mattaceunk Project in a run-of-river mode with year round use of the 4-foot-high flashboards such that average daily outflow approximates average daily inflow*."

"*For unplanned deviations lasting 3 hours or less that do not result in visible environmental effects, the licensee must file an annual report, by March 1, describing each incident that occurred during the prior January 1 through December 31 time period*."

Condition B of the Maine DEP Water Quality Certification for the Mattaceunk Project states in part:

*"Except as temporarily modified by: 1) approved maintenance activities, 2) extreme hydrologic conditions 3) emergency electrical system conditions, or 4) agreement between the Applicant, the Department, and state and/or federal agencies as appropriate, a total minimum flow of 1,674 cfs or inflow, whichever is less, and a daily average minimum flow of 2,393 cfs from July 1 through September 30 or 2,000 cfs from October 1 through June 30, shall be released from the Project to protect downstream fish and aquatic resources, unless inflow is less than the stated daily average minimum flows, in which case outflow from the Project would equal the inflow to the Project*."

As indicated above, McKay Station (part of the Ripogenus Project) also tripped offline during this event; however, the 400 cfs emergency outage flow was restored to the river within 5 minutes via the station's minimum flow system, and then the normal 1,000 cfs minimum flow was restored by 09:58 hrs. Thus, the McKay Station trip is not reportable to FERC, since there was no excursion of the Project's hourly average minimum flow requirements.



GLHA is still investigating and collecting information on this event, which will be detailed in a report to FERC within 10 days. I will copy you on this report, but in the meantime please let me know if you have any comments or questions.

Re: Response to MDIFW Comments and Study Requests for the Ripogenus Hydroelectric Project (FERC No. 2572-133) and Penobscot Mills Hydroelectric Project (FERC No. 2458-247) filed on October 8, 2021

Dear Secretary Bose:

I worked for then GNP; and later the licensee, GLHA, from 1977-2002 as a fisheries biologist with my primary responsibly being West Branch of the Penobscot River (WB) drainage data collection and analysis, coauthoring Big A, Ripogenus, Penobscot Mills, and the Storage Project FERC applications and supervising enhancement and mitigation measures. My colleagues and I collected the historical fisheries data so often referenced in the subject proceedings. These (1980s) data are antiquated and should NOT be used to base decisions that will remain in effect for 30 years.

My comments are directed to the Department of Inland Fisheries and Wildlife's (MeDIFW) October 8, 2021 comments and study request's filing. While I generally agree and support goals expressed, I have issues with MeDIFW's focus. The licensing of the above referenced projects is an evidentiary proceeding. Without substantial date collections, before (1980s) and current/after (2022) fisheries comparison will be impossible. Most alarming is MeDIFW's willingness to accept historic angler use and salmonid growth and catch data. MeDIFW makes this statement despite asserting that *"there has been a significant change in the quality of the landlocked salmon fishery in both locations*". Neither the licensee nor MeDIFW have collected quantifiable WB riverine fisheries information in the last ten plus years despite significant changes in water management.

I have listed six (6) topics of concern below along with the relevant MeDIFW comment(s) and my response(s)

1) "*MDIFW concurs with the Licensee that there is an extensive history of inland fisheries studies associated with the Ripogenus Project completed in preparation for the 1996 license, and The Maine Department of Inland fisheries and Wildlife's (MeDIFW) comment "extensive histories of inland Fisheries studies … in preparation for the 1996 license "..."and the need to duplicate these (old) studies makes little biological sense*."

MeDIFW concurrence with the licensee makes little sense. If only for management purposes, after a forty year data hiatus, requiring new studies of the all WB waters is a logical conclusion. The river below McKay Station is one of Maine's premier fisheries with regional and national significance. The referenced studies (used in the 1992 license application) were at a minimum nine years old in 1996 and now approach 40 years old; inadequate even for future fisheries management purposes e.g., bag and size limits, terminal gear restrictions. Technology and collection methods have been greatly improved. Project operations below McKay Station have been drastically altered due to peaking operations, extreme impoundment drawdowns, many minimum flow (1100 cfs) events and some "outage" flows. The degree of fish and aquatic community degradation needs to be identified. There is a huge 40 year data gap. Repeating historical salmonid West Branch (McKay to Dolby Stations) studies and determining current population levels will determine if, in fact, there have been changes. "Repeating historic studies" (using current technology) is exactly what FERC must require.

1a) *"…there has been a significant change in the quality of the landlocked salmon fishery in both (impoundment and river ..ed) locations.*

While I concur with this general statement, for the WB below McKay Station this comment requires some supporting factual data. Other than some volunteer (biased) 'angler survey' boxes results and antidotal reports, no data exists. While MeDIFW and the Greenville region has demonstrated extreme competence (note Moosehead Lake, [FERC P-2671] fishery successes), subjective judgement is not acceptable. FERC must require quantifiable angler use and catch and salmonid growth and survival data. Without current, quantifiable fisheries data, interested parties will be unable to comment and FERC will not be able to make an informed 30-year licensing decision.

MeDIFW was silent on the declines in lake white fish (Coregonus clupeaformis) populations in the Ripogenus impoundment. The status of burbot (Lota lota) is not mentioned. Both species provide popular fisheries in nearby lakes and are vulnerable to extreme drawdowns during and after spawning (note: burbot spawn in the confluence of the upper West Branch).

2)"… *these studies need not be duplicated unless there are identified data gaps, changes in operation that may Impact the fisheries resources*."

As noted above, project operations have been drastically changed (without archival ***hourly flow*** and lake level data, it is impossible for MeDIFW or other interested parties to know the degree of change). Relatively stable flows are gone, replaced by peaking operation. The licensee (but not necessarily MeDIFW) was well aware of the impact of peaking when it filed the PAD as it sponsored (peaking and ramping) studies on the Magpie and Batchawana Rivers (Ontario, CA). If they doubt their own studies, the literature is replete with supporting literature

**3)** *"….review and fine tune the water management for the Ripogenus Project*"

MeDIFW suggests "fine tune the water management for the Ripogenus Project". "Water management" used in conjunction with the Ripogenus Project is an oxymoron. There has been no water management. The current operation is generate and drain. The Ripogenus impoundment storage has been drawn down and managed solely for market driven power generation. "More than fine tune", FERC needs require a (peer reviewed) water management plan that benefits public users (anglers, boaters, camp owners) native Americans and all aquatic and terrestrial resources.

**3a)** *Flow changes of less than 25% per hour (ramping rate) can mitigate impacts from peaking power*.

I concur with MeDIFW's suggestion of ramping during peaking operations but it is too limited. Both up and down ramping rates are equally important in mitigating (peaking) impacts. In fact, the Licensee's Storage Project P-2634, 401 WQC requires a ramping plan. "The applicant shall develop and implement a plan to ramp flows down in Caucomgomoc Stream prior to the required flow reduction to 35 cfs on June 7, in order to prevent stranding of aquatic organisms." Most recent FERC licenses contain ramping prescriptions, often developed from instream studies. The

area in the one mile reach immediately below McKay Station features steep walls and high gradients and is "flow sensitive". It also the area salmon now (post peaking) appear to favor during July and August and an area dominated by hydropsychid caddis (the major salmonid "summer" food source). The combination of the above factors clearly dictates a need for study rather than generic prescriptions. FERC must include (for all facilities) the same ramping prescriptions (based on instream flow study results) as contained in other FERC licensed peaking projects.

**(4)** *"The decline in salmon growth is related primarily to a surplus of salmon in the impoundment and resulting lack of smelt, the primary forage fish".*

I concur with the "decline in salmon growth" (and condition) but not necessarily the reason(s) for the "lack of smelt". If fact, the "lack of smelt" has not been quantified as no (smelt) sampling e.g., trawls, gill nettings, has, to my knowledge, been undertaken in the Ripogenus or other impoundments. MeDIFW assumes this to be a predator (salmon)/prey (smelt) imbalance. While this is possible, other possibilities exist, including loss/shifting of littoral areas, a shift in the zooplankton community, and/or a shift in the smelt age distribution structure. The smelt biomass may be stable but there may have been change in the age structure (more bigger smelt). Agency and NGO study requests should, when implemented, clarify problems with smelt and plankton communities provided Normandeau Associate's 1981 studies (see Big A, FERC P-3779) are used as baseline.

**(5)** **"***It has been well-documented that the smelt drift in the river is important to salmon growth for the riverine population*."

I agree that smelt drift is important, in fact it is critical, to meeting riverine (WB) salmon management goals. While smelt drift below McKay Station has (apparently) declined, MeDIFW's statement is based on fragmentary data. There is a need to document volume and seasonality of the current export/drift of smelt though McKay, North Twin, Millinocket and Dolby Stations. These data are needed to identify present smelt availability (as forage) as well as future (MeDIFW) fisheries management and flow goals. These collections should not be *the responsibility of MeDIFW.*

**(6)** *The Licensee and MDIFW have verified the presence of young wild salmon and brook trout in the (Holbrook side) channel. We simply request that the Licensee*

*continue to operate and maintain the Holbrook Side Channel as outlined in the current license (article 406).*

MeDIFW's request to continued operations in is not enough. The licensee has demonstrated its inability to comply with a litany of license articles, including the Holbrook bypass. In the late 1990's, I conducted the initial survey of the watered Holbrook Side Channel and confirmed the production of juvenile salmon (young-of-the year, parr). This enhancement measure was a success. This year (2021), I visited the "side channel" on several low flow occasions. My professional judgement is that juvenile salmon habitats are seriously degraded, if not eliminated, during low flow events. Salmon production goals are lost under outage flow events. A "continuation" of present operations with low flows e.g., 1100 cfs, is not acceptable. Annual monitoring the Holbrook side channel should be resumed. FERC must ensure Article 406 measures are guaranteed in the future.

The licensing of the Ripogenus and Penobscot Mills Projects will result in a 30 year license. Resource agencies and stakeholders have requested studies that will provide FERC with information necessary to "balance" power and non-power interest. The licensee's contention is that "only data gaps" need to be fill-in, is baseless. The licensee's presented outdated, 30-40 year old studies conducted prior to change to peaking operations as a substitute to any onsite presence. The absence of any "recent" data demonstrates the need for current state -of-the-art fisheries and aquatic communities studies. FERC should reject any reliance on 40 year old data, and require studies suggested by the agencies and NGOs. The burden of proof as to the health of all projects' fisheries and aquatic communities falls on the licensee.

Thank you for the opportunity to respond

RE: Ripogenus Project FERC No. P-2572-133
Study Request; Creel Survey, West Branch of the Penobscot River

Study Request; Conduct a creel survey and determine daily and annual West Branch of the Penobscot River angler use, effort, catch, method (drift boat, watercraft, wading, etc.) and (riverine) location of anglers fishing between Ripogenus Dam and the base of Pockwockamus Falls

A creel survey is a standard method for determining angler use and catch from one or more waters. Typically a clerk, either stationary or mobile, counts and when possible, interviews anglers during predetermined dates and times. On-site counts (and interviews) are more practical and robust than other possible methods such as aerial, on-site volunteer (angler) boxes with "fill-in" forms or "mail-in" surveys. Creel surveys, as described above, are commonly used by MeDIFW and fisheries agencies across the country.

In reading comments, and study plan requests, I have seen no such requests for a West Branch of the Penobscot River (WB) creel survey. Such a study of angler use, catch and effort lays the foundation for future licensing decisions making as well as supporting current/future State of Maine fisheries management goals. The Maine Department of Inland Fisheries and Wildlife (MeDIFW) recently (November 2, 2021) filed a (draft) *FISHERIES STRATEGIC PLAN 2021-2035, Vol I (*MeDIFW Plan) that listed prioritized fisheries goals. General fisheries goals include "… Maintain healthy fish populations and their habitat. Ensure freshwater fish populations remain healthy and are sustainably managed into the future." In order to obtain the MeDIFW Plan's primary goals, a number of secondary actions are required;

"Conserve native fish species, particularly those exhibiting population decline, …"

"Manage for sustainable harvest of sport fish"

"Promote and direct conservation actions, including conservation of riparian habitat, habitat restoration, and habitat connectivity targeting the state's highest priority wild native fisheries". Brook trout and landlocked salmon are two of the native fish species referenced in the MeDIFW's Plan. (Emphasis added)

- *1.Describe the goals and objectives of each study proposal and the information to be obtained;*

  The goal of the proposed study is to record existing WB angler use (date, time, location(s) fished and terminal gear), and catch (species, size and number). Angler use and catch presented by the licensee in the riverine areas below Ripogenus Dam is outdated. Current (daily/annual) angler use and catch needs to be enumerated and then evaluated.

  The licensee states in the PAD that the existing body of (fisheries) information is adequate and that no new information is required. The referenced PAD fisheries studies are, at a minimum 35 years old and do not reflect changes in project operations. In order to compare (1980s) baseline conditions described in the 1992 EIS, current (2022) angler use and catch information is necessary. In addition to providing critical fisheries information to all interested parties, a creel survey will meet goals described in the (draft) MeDIFW Plan. In regard to Landlocked Atlantic Salmon (salmon), these goals include;

  • Advocating for in-watershed land and water management practices that maintain or enhance spawning and rearing habitats for wild populations, where populations are not overabundant
  • Continue current monitoring and assessment to be responsive to changes in abundance and condition over time
  • Reevaluate salmon waters that haven't been recently assessed to ensure existing regulations reflect current management goals and angler behavior. (Emphasis added)

- 2*. If applicable, explain the relevant resource management goals of the agencies or Indian tribes with jurisdiction over the resource to be studied;*

There is no current (quantifiable) WB fisheries information on which sound management decisions can be based. A creel survey of the West Branch fisheries (salmon, brook trout) below Ripogenus Dam and extending downstream to Pockwockamus Falls will meet goals (see above) put forth in the (draft) MeDIFW Plan.

- *3. If the requester is not a resource agency, explain any relevant public interest considerations in regard to the proposed study*;

  I am a (retired) private individual who worked for then GNP and was responsible for (WB) fisheries study designs, data collection and analysis, and coauthored the 1992 Ripogenus FERC License application. I had oversight of the Holbrook Nursey Channel enhancement measure (Article 406). I remain interested in the WB fish and aquatic communities and fish there frequently.

  Study results will improve MeDIFW fisheries management options e.g., length of season, increased/decreased catch and length limits, thus are very much in the public interest. A return to the fishery conditions of 1980's will benefit the local economy and as well as local, regional and national anglers.

- 4*. Describe existing information concerning the subject of the study proposal, and the need for additional information*;

  <u>There is NO existing WB fisheries (creel survey) study proposal</u>, thus this is NOT an additional information request. Studies provided by the licensee are PRE-Peaking and thus, irrelevant. There is no current (quantifiable) fisheries information for the WB between Ripogenus Dam and the base of Pockwockamas Falls. Critical data gaps exist for angler use, catch, and (riverine) location and for salmon and brook trout (trout) growth, survival and spawning history.

- *5. Explain any nexus between project operations and effects (direct, indirect, and/or cumulative) on the resource to be studied, and how the study results would inform the development of license requirements*;

  The Licensee has dramatically changed project operations from a relatively stable base flow to a peaking operation. The changes have had a devasting impact on angler use and salmon growth, abundance, choice of habitat and movement (personal observations). When compared to the baseline data used in the EIS, 2022-2023 WB creel surveys will demonstrate changes in

angler use and effort and salmon and trout abundance (catch rates) and to a lesser degree, choice of habitat and movement. (NOTE: Condition (factors) and growth rates will be provided by some yet to be determined collection method e.g., electrofishing, seining, gill netting, etc.)

- 6. *Explain how any proposed study methodology (including any preferred data collection and analysis techniques, or objectively quantified information, and a schedule including appropriate filed season(s) and the duration) is consistent with generally accepted practice in the scientific community or, as appropriate, considers relevant tribal values and knowledge;*

  The proposed creel survey should duplicate the 1978 study plans developed by MeDIFW (Greenville Region) and Great Northern Paper (GNP). As the EIS is based on GNP's 1979-1988 creel survey results, the suggested study and methodology should be acceptable to FERC and participating parties. These methods are fully described in Appendix IX p-183 of the FERC Ripogenus Project License Application.

  For the level of information desired, angler surveys should occur;

  May and September – four (10h) days, ending at sunset

  June -August – four (12h) days, ending a half hour after sunset

  Sampling days should be divided between weekdays and weekend/holidays

  I assume that the Licensee has retained a copy of the GNP computer program designed to input daily angler, use, catch and effort based on stratified random sampling.

7. *Describe considerations of level of effort and cost, as applicable, and why proposed alternative studies would not be sufficient to meet the stated information needs*.

Cost $35,000

No alternative WB creel survey (or study) of angler use and catch has been presented. The licensee has stated 35 year-old data collected during historical "relatively stable" base flows is comparable to existing peaking operations and the resulting periodic minimum flows e.g. 1100 cfs. There are

no fisheries data or literature references that supports the licensee's statements. In fact, there is antidotal evidence and peer reviewed literature to the contrary.

The licensee argues that present operations are maintaining the fisheries at 1980's levels. A creel survey(s) will either refute or confirm the licensee's assertions. Data collection will also meet goals set forth in the (draft) MeDIFW Plan. The burden of proof falls on the licensee.

FEDERAL ENERGY REGULATORY COMMISSION
Washington, DC 20426
November 22, 2021

OFFICE OF ENERGY PROJECTS

Project Nos. 2572-133 & 2458-247 –
Maine
Ripogenus Hydroelectric Project
Penobscot Mills Hydroelectric Project
Great Lakes Hydro America, LLC

**VIA FERC Service**

**Reference: Scoping Document 2 for the Ripogenus Hydroelectric Project (P-2572-133) and Penobscot Mills Hydroelectric Project (P-2458-247)**

To the Parties Addressed:

The Federal Energy Regulatory Commission (Commission) is currently reviewing the Pre-Application Document (PAD) submitted by Great Lakes Hydro America, LLC (GLHA), a subsidiary of Brookfield Renewable, for relicensing the Ripogenus Hydroelectric Project (FERC No. 2572) and the Penobscot Mills Hydroelectric Project (FERC No. 2458) (collectively referred to as the "Projects"). The Projects are located on the West Branch of the Penobscot River and Millinocket Stream in Piscataquis and Penobscot Counties, Maine. The Projects do not occupy any federal land.

Pursuant to the National Environmental Policy Act (NEPA) of 1969, as amended, Commission staff will prepare an environmental document (NEPA document) which will be used by the Commission to determine whether, and under what conditions, to issue a new license for the Projects. To support and assist our environmental review and determine the level of analysis needed, we are beginning the public scoping process to ensure that all pertinent issues are identified and analyzed, and that the NEPA document is thorough and balanced.

Our preliminary review of the environmental issues to be addressed in our NEPA document was contained in Scoping Document 1 (SD1), which was issued on August 10, 2021. We requested comments on SD1 to hear the views of all interested

agencies and entities on the scope of issues that should be addressed in the NEPA document. Due to restrictions on mass gathering related to COVID-19, Commission staff was unable to conduct any on-site scoping meetings or an on-site environmental site review. Rather, two virtual scoping meetings and a virtual environmental site review were held. Based on comments these scoping meetings and site review, and written comments that have been filed, we have updated SD1 in the enclosed Scoping Document 2 (SD2) to reflect our current view of issues and alternatives to be considered in the NEPA document. ***Key changes from SD1 to SD2 are identified in bold and italicized type***.

SD2 is being distributed to GLHA's distribution list and the Commission's official mailing list (*see* section 7.0, *Mailing Lists*, of the attached SD1). If you wish to be added to, or removed from, the Commission's official mailing list, please send your request by email to Mailto:FERCOnlineSupport@ferc.gov, or via U.S. Postal Service mail to: Kimberly D. Bose, Secretary, Federal Energy Regulatory Commission, 888 First Street NE, Room 1A, Washington, DC 20426. Submissions sent via any other carrier must be addressed to: Kimberly D. Bose, Secretary, Federal Energy Regulatory Commission, 12225 Wilkins Avenue, Rockville, Maryland 20852. All written or emailed requests must specify your wish to be added to, or removed from, the mailing list, and must clearly identify **Ripogenus Hydroelectric Project (P-2572-133)** and/or **Penobscot Mills Hydroelectric Project (P-2458-247)** on the first page.

The enclosed SD2 supersedes SD1. SD2 is issued for informational use by all interested parties; no response is required. If you have any questions about SD2, the scoping process, or how Commission staff will develop the NEPA document for the Projects, please contact Allan Creamer at (202) 502-8365, or at allan.creamer@ferc.gov. Additional information about the Commission's licensing process and the Projects may be obtained from the Commission's website, www.ferc.gov.

## Ripogenus Hydroelectric Project (FERC No. 2572-133)
## Penobscot Mills Hydroelectric Project (FERC No. 2458-247)

## 1.0 INTRODUCTION

The Federal Energy Regulatory Commission (Commission or FERC), under the authority of the Federal Power Act (FPA),[1] may issue licenses for terms ranging from 30 to 50 years for the construction, operation, and maintenance of non-federal hydroelectric projects. On June 11, 2021, Great Lakes Hydro America, LLC (GLHA), filed notices of intent and a pre-application document (NOI/PAD) for new licenses for the Ripogenus Hydroelectric Project No. 2572-133 (Ripogenus Project) and the Penobscot Mills Hydroelectric Project No. 2458-247 (Penobscot Mills Project) (collectively, the "Projects"). The Projects are located on the West Branch of the Penobscot River and Millinocket Stream in Piscataquis and Penobscot Counties, Maine (figure 1). A detailed description of the Projects ***and the Projects' operation*** is provided in section 3.0, *Proposed Actions and Alternatives*. The Projects do not occupy federal lands.

The National Environmental Policy Act (NEPA) of 1969,[2] the Commission's regulations, and other applicable laws require that we independently evaluate the environmental effects of relicensing the Projects as proposed, and consider reasonable alternatives to the proposed actions.[3] We will prepare an environmental document (NEPA document) that describes and evaluates the probable effects, if any, of the licensee's proposed actions for the Projects and alternatives to the proposed actions. The Commission's scoping process will help determine the required level of analysis and satisfy the NEPA scoping requirements, irrespective of whether the Commission issues an environmental assessment (EA) or an environmental impact statement (EIS).

[1] 16 U.S.C. § 791(a)-825(r).

[2] 42 U.S.C. §§ 4321-4370(f).

[3] The Council on Environmental Quality (CEQ) issued a final rule on July 15, 2020, revising the regulations under 40 C.F.R. Parts 1500 – 1518 that federal agencies use to implement NEPA (*see* Update to the Regulations Implementing the Procedural Provisions of the National Environmental Policy Act, 85 Fed. Reg. 43,304). The Final Rule became effective on, and applies to any NEPA process begun after, September 14, 2020. Commission staff intends to conduct its NEPA review in accordance with CEQ's new regulations.

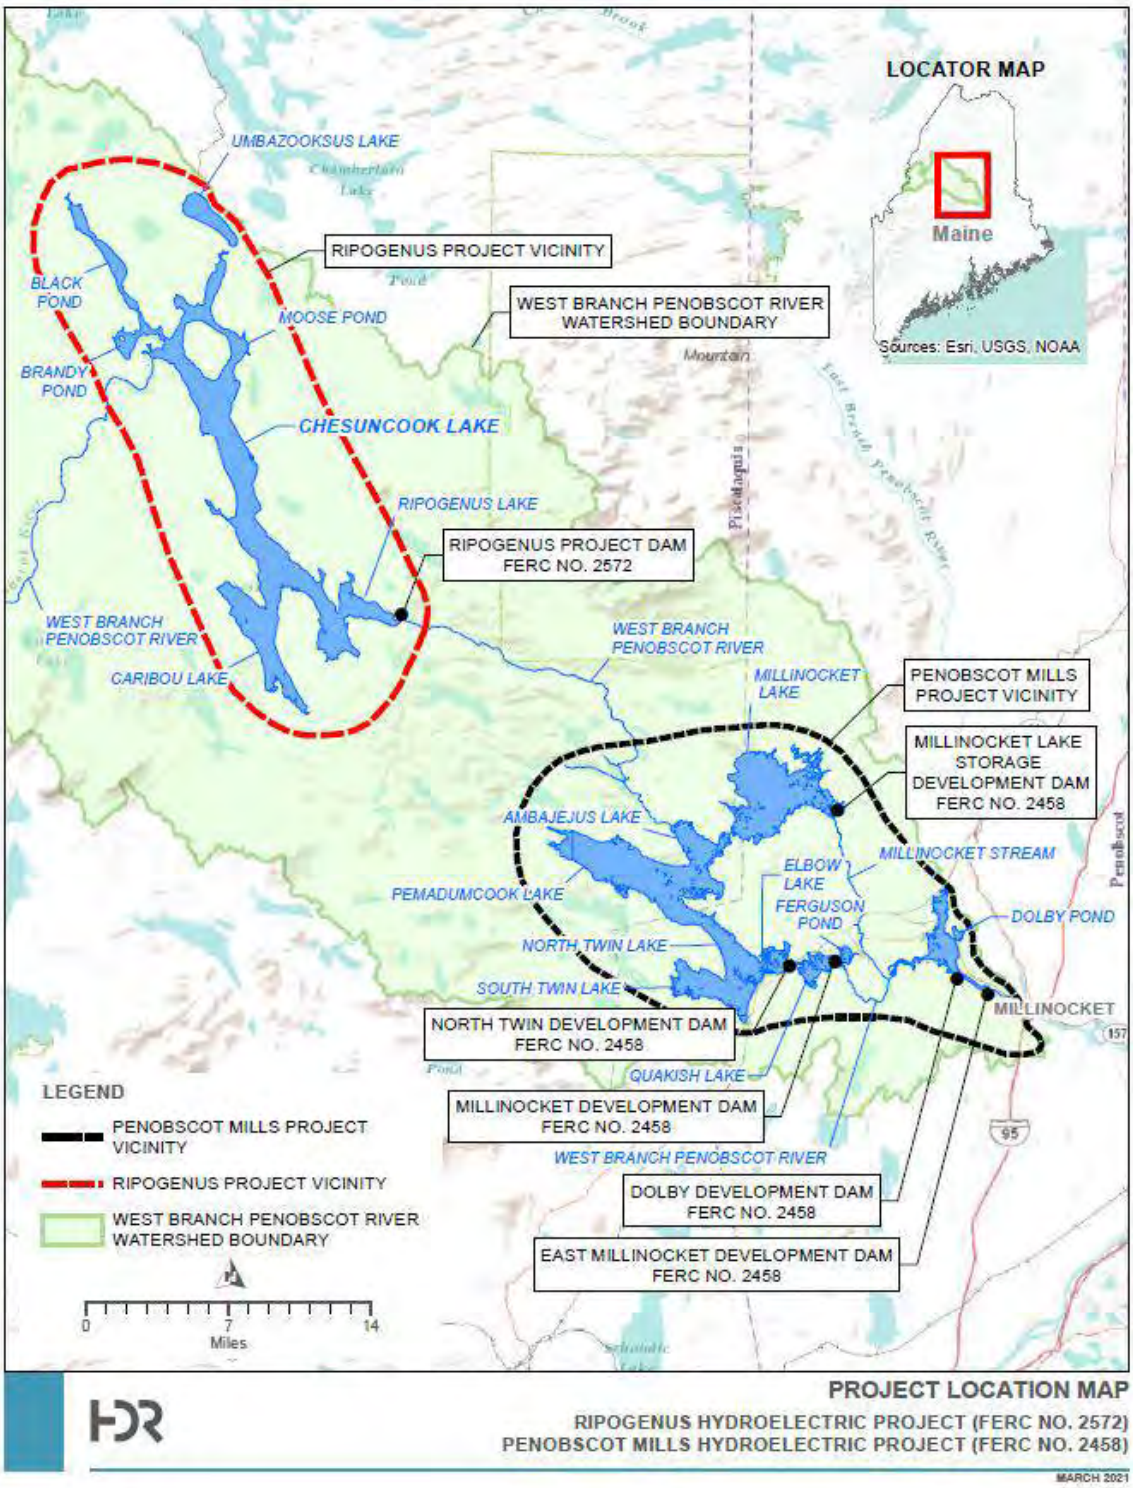

Figure 1. Location of the Ripogenus and Penobscot Mills Hydroelectric Projects (source: PAD).

# 2.0 SCOPING

This Scoping Document 2 (SD2) is intended to advise all participants as to the proposed scope of the NEPA document and to seek additional information pertinent to this analysis. This document contains: (1) a description of the scoping process and ***schedule for developing*** the license applications ***and NEPA document***; (2) a description of the licensee's proposed actions and alternatives to the proposed actions; (3) a preliminary identification of environmental issues ***and proposed studies***; (4) ***a proposed outline for the NEPA document;*** and (5) a preliminary list of comprehensive plans that are applicable to the Projects.

## 2.1 PURPOSES OF SCOPING

Scoping is the process used to identify issues, concerns, and opportunities for enhancement or mitigation associated with a proposed action. According to NEPA, the process should be conducted early in the planning stage of the project. The purposes of the scoping process are as follows:

- invite participation of federal, state, and local resource agencies, Native-American Tribes, non-governmental organizations (NGOs), and the public to identify significant environmental and socioeconomic issues related to the proposed Projects;

- determine the resource issues, depth of analysis, and significance of issues to be addressed in the NEPA document;

- identify reasonable alternatives to the proposed actions that should be evaluated in the NEPA document;

- Solicit***, from participants,*** available information on the resources at issue; and

- determine the resource areas and potential issues that do not require detailed analysis during review of the Projects.

## 2.2 SCOPING COMMENTS

Commission staff issued Scoping Document 1 (SD1) on August 10, 2021, to enable resource agencies, Native-American Tribes, NGOs, and the public to more effectively participate in, and contribute to, the scoping process. In SD1, we requested clarification of preliminary issues concerning the Projects and identification of any new issues that needed to be addressed in the NEPA document. Due to restrictions on mass

gatherings related to Novel Coronavirus Disease (COVID-19), Commission staff was unable to conduct any on-site scoping meetings and participate in any in-person environmental site review. Instead, on September 9, 2021, we conducted virtual scoping meetings and GLHA conducted a virtual environmental site review. The scoping meetings were transcribed by court reporter(s). We also solicited written comments, recommendations, and information on SD1.

We revised SD1 following the scoping meetings and after reviewing comments filed during the scoping comment period, which ended October 9, 2021. SD2 presents our current view of issues to be considered in the NEPA document. ***To facilitate review, key changes from SD1 to SD2 are identified in bold, italicized type***.

In addition to comments received at the virtual scoping meetings, the following entities filed written comments on the PAD or SD1.[4]

| **Entity** | **Date Filed**[5] |

All comments received are part of the Commission's official record for the project. Information in the official file is available for review on the Commission's website at https://www.ferc.gov, using the "eLibrary" link. At this time, the Commission has suspended access to the Commission's Public Reference Room due to the proclamation declaring a National Emergency concerning COVID-19 issued by the President on March 13, 2020. For assistance, please contact FERC at FERCOnlineSupport@ferc.gov, (866) 208-3676 (toll free), or (202) 502-8659 (TTY).

## 2.3 ISSUES RAISED DURING SCOPING

During the scoping meetings and scoping comment period, we received comments on GLHA's PAD and the Commission staff's SD1. In addition, participants filed study requests. The majority of comments identified concerns about current project operations and potential project effects on water quality, diadromous fish passage, fish and wildlife resources and habitat, recreational opportunities and boating access, and cultural resources. Many of these comments fall within the scope of issues identified in SD1 and will be addressed as part of the environmental analysis of the proposed Projects. Therefore, for many of the comments, no modifications to the scoping document were necessary. However, several issues were raised in the comments that either were not identified, or not adequately described, in SD1. We have modified SD2 accordingly. ***Below, we summarize these comments and provide responses by subject area***.

The summary does not address every comment received during the scoping process. For example, SD2 does not address comments on GLHA's PAD or requests for information. Nor does SD2 address recommendations for protection, mitigation, and enhancement (PM&E) measures, as the need for these measures will be analyzed in the NEPA document or any license orders that are issued for the Projects. We will request terms, conditions, recommendations, and comments when we issue our Ready for Environmental Analysis notice. SD2 also does not address administrative comments or recommendations, such as requests for changes to the mailing list. Those items will be addressed separate from the NEPA document. Lastly, we do not address comments on

the need for environmental studies, as these comments will be considered during the study plan development process.

**General**

Comment: Due to the complex nature of the Projects and their effects, NMFS recommended that Commission staff analyze the effects of the Projects in an EIS, instead of an EA. In support of its recommendation, NMFS states: (1) comments on the PAD from many stakeholders make a compelling argument that the Projects' dams and their operation likely result in considerable negative ecological effects to the West Branch; (2) the new flow and impoundment management regimes implemented since the last relicensing may affect the endangered Gulf of Maine distinct population segment of Atlantic salmon and its designated critical habitat; and (3) relicensing is expected to generate significant public interest.

Response: Based on our initial review of the project and the definition of "significantly" in 40 C.F.R. §1508.27, we have not yet decided what type of NEPA document will be prepared in this case. As we indicated in SD1, our decision on whether to prepare an EA or EIS will be determined after the license application is filed and we fully understand the scope of effects and measures under consideration. Nonetheless, we have modified Section 6.0, *EA Preparation Schedule*, to say that we intend to prepare a draft and final NEPA document and provide an appropriate public comment period on our draft NEPA document. This scoping process will satisfy NEPA requirements irrespective of whether an EA or EIS is issued by the Commission.

Comment: NMFS, American Whitewater and the Appalachian Mountain Club, the Penobscot Indian Nation, and the Restorative Justice Institute requested that the Commission include, in its NEPA document, an alternatives analysis that includes decommissioning and removal of the Ripogenus and Penobscot Mills dams.

Response: As noted in Section 3.4.3, *Project Decommissioning*, the Commission has held that decommissioning is not a reasonable alternative to relicensing in most cases, and the Commission does not speculate about possible decommissioning measures at the time of relicensing, but rather waits until an applicant actually proposes to decommission a project, or a participant in a relicensing proceeding demonstrates that there are serious resource concerns that cannot be addressed with appropriate license measures and that make decommissioning a reasonable alternative. In this case, GLHA does not propose decommissioning, nor does the record, to date, demonstrate that there are serious resource concerns that cannot be mitigated if the projects are relicensed.

For example: (1) while the projects may affect the federally listed Gulf of Maine distinct population segment of Atlantic salmon in the mainstream Penobscot River due to operational and flow releases at the Projects,[6] the West Branch does not contain critical habitat for Atlantic salmon, nor is the habitat in the West Branch essential to achieve the species' recovery goals in the Penobscot River watershed;[7] (2) restoration of American shad, river herring, and sea lamprey is not currently a goal for the West Branch, and upstream and downstream fish passage is not currently necessary for Atlantic salmon or other anadromous species;[8] (3) there are no Tribal lands affected by the Projects; (4) the West Branch is not a protected river; (5) no water quality, recreation, or historic property issues raised during scoping would necessitate decommissioning and/or dam removal; and (6) there are a number of businesses, seasonal camps, and residences surrounding the project impoundments that rely on the projects' impoundments.

Therefore, we do not intend to include project decommissioning with dam removal as an alternative to relicensing the Projects in the NEPA document.

Comment: Michael Hudson recommended that the environmental review process include an alternative with lake level restrictions for the Ripogenus Impoundment.

Response: As described in section 4.1, *Resource Issues*, we intend to address lake level drawdowns and fluctuations on Ripogenus Impoundment, and any associated effects on environmental and recreational resources, as part of our environmental review of the Projects. Our environmental review will inform the Commission's decision as to any lake level restrictions to be included in any new license issued for the Ripogenus Project.

Comment: The Penobscot Indian Nation noted that SD1 refers to the West Branch of the Penobscot River downstream from Stone Dam as the "Back Channel," which it considers offensive, as it diminishes the importance of the river channel and creates confusion as to what section of the river is being referenced. The Penobscot Indian Nation asks that the term "Back Channel" not be used. Maine Council TU noted that GLHA uses terms like "bypassed reach" and "Back Channel," which it points out can minimize the effects of the Projects. Maine Council TU requests that different language that more accurately describes the affected reach be used.

[6] *See* NMFS's October 8, 2021 Comments at 2.

[7] *Id*. at 8 and 9.

[8] *See* Maine DMR's October 12, 2021 Comments at 6.

Response: The terminology in the scoping document has been revised accordingly.

Comment: Daniel McCaw of the Penobscot Indian Nation asked, during the September 9, 2021, scoping meeting, about how the 2018 *American Rivers* court case, which vacated Alabama Power Company's project license for the Coosa River Project No. 2146 and remanded the matter back to the Commission for further consideration, affects the Commission's relicensing process for the Projects; specifically related to baseline conditions. The Penobscot Indian Nation seeks to understand the *American Rivers* court case, the connections to the cumulative effects of the Projects, and the use of the historic, pre-dam conditions for analysis by the Commission.

Response: As stated by Commission staff during the September 9, 2021, scoping meeting, the D.C. Circuit Court of Appeals, in *American Rivers v. FERC* did not change the Commission's baseline.[9] Rather, the Court held that the Biological Opinion prepared by FWS for the Coosa River Project did not appropriately consider the degradation to the environment caused by the project's operation and its continuing impacts in establishing an environmental baseline under the Endangered Species Act.[10] While this court case does not change the Commission's definition of baseline conditions, Commission staff does consider, in cases where it is appropriate, past and on-going project effects in its environmental review of a project. Therefore, no changes to the scoping document are necessary.

Comment: NMFS recommended that the Commission work with the Penobscot Indian Nation to understand and fully consider their positions and interests regarding the potential continued operation of the Projects.

Response: We intend to work with all stakeholders, including the Penobscot Indian Nation throughout the relicensing process for the Projects. No changes to the scoping document are necessary.

**Federal Land**

Comment: The Penobscot Indian Nation disagreed with Commission staff's characterization that the Ripogenus Project and the Penobscot Mills Project do not occupy any federal lands. The Penobscot Indian Nation states that it has inhabited the Penobscot River, including the West and East Branches, from time immemorial and that

[9] *American Rivers v. FERC*, 895 F.3d 32 (D.C. Cir. 2018).

[10] *Id.* at 46.

these areas represent their aboriginal lands. The Penobscot Indian Nation also stated that it has not ceded its aboriginal title to the Penobscot River and its branches in any treaty, nor has Congress extinguished that aboriginal title. Thus, the Penobscot Indian Nation contends that the Projects, which are located on the West Branch, occupy federal lands in the form of the Penobscot Reservation.

Response: Beginning with the 1984 relicensing of the West Enfield Project on the Main Stem Penobscot River, the Commission has consistently concluded that the United States does not have a proprietary interest in the aboriginal lands (i.e., the river islands) of the Penobscot Nation, and so these lands are not a "reservation" within the meaning of the Federal Power Act.[11] The Penobscot Indian Nation's comments did not provide any information that would change that finding. Therefore, the scoping document has not been modified.

**Project Facilities**

Comment: GLHA provided several corrections and clarifications to the descriptions in SD1 for project facilities associated with the Millinocket, Dolby, and East Millinocket Developments.

Response: Section 3.1.1., *Project Facilities-Penobscot Mills Project*, has been revised accordingly.

**Geology and Soils**

Comment: American Whitewater and the Appalachian Mountain Club recommended that the NEPA document include an analysis of the effects of flow diversion and dewatering of the natural river channel downstream from Ripogenus Dam and Stone Dam on sediment transport.

Response: The NEPA document for the Ripogenus and Penobscot Mills Projects will include an analysis of the Projects' operational effects on sediment transport in the West Branch downstream from Ripogenus Dam and Stone Dam. Section 4.1.1, *Geologic and Soils Resources*, has been revised accordingly.

[11] *Bangor Hydro-Electric Co.*, 27 FERC ¶ 61,467, at 61,875 (1984); *see also Bangor Hydro-Electric Co.*, 83 FERC ¶ 61037, at 61083 (1998).

## Water Resources and Project Operation

Comment: Numerous stakeholders commented on low lake levels on the Ripogenus Impoundment, as well as the effects of drawdowns within the Ripogenus, Millinocket Lake Storage Dam, and North Twin Impoundments on littoral and riparian habitats in, and around, the impoundments. These stakeholders recommend that the NEPA document include an analysis of the effects of drawdowns on the Ripogenus, Millinocket Lake Storage Dam, and North Twin Impoundments on the impoundments' littoral zone, riparian areas, and associated aquatic and wildlife communities; angling opportunities on the Ripogenus Impoundment; recreation access to, and use of, Caribou Lake, Chesuncook Lake, and Ripogenus Lake; public safety; water supply to properties around the Ripogenus Impoundment; educational opportunities; and the aesthetics of the area.

Response: As indicated in sections 4.1.2, *Water and Aquatic Resources*, 4.1.3, *Wildlife and Botanical Resources*, and 4.1.5, *Recreation, Land Use, and Aesthetics*, drawdowns and low lake levels within the Ripogenus Impoundment on environmental and recreational resources will be analyzed in the NEPA document. Sections 4.1.2, 4.1.3, and 4.1.5 have been revised to clarify the specific resources to be analyzed.

Comment: NMFS, Maine DIFW, Edward Spear, John Kirk, III, Sarah Sindo, and Miles Puleio commented on flow management in the West Branch and the Projects' existing Water Use Plan and its effects on flows in the West Branch and mainstem of the Penobscot River. Stephen Heinz commented on the effects of climate change on operating the Projects and the hydrology of the West Branch.

Response: As indicated in sections 4.1.2, *Water and Aquatic Resources*, the NEPA document will include an analysis of continuing to operate the Projects on water quantity and flow in the West Branch, including effects on impoundment levels and downstream flooding. Section 4.1.2 has been revised to indicate that we intend to evaluate the effects of the existing Water Use Plan and alternatives to that plan, as well as the scope of downstream affects.

With regard to climate change, we are not aware of any available climate change model or assessment that would support, with any degree of accuracy and reliability, prediction of water availability at the individual project level. Therefore, information from general climate research and modeling will not be considered as part of the NEPA review process and development of the NEPA document. However, historical data for project operations and flows can be used to evaluate trends in, and changes to, the hydrology of the West Branch over time. This information will be used to establish the

baseline for the environmental analysis of aquatic resources, as well as evaluating potential project effects on those resources.

Comment: FWS, NMFS, and American Whitewater and the Appalachian Mountain Club, commented on the description in the scoping document of how the Projects operate. Specifically, the commentors state that the projects do not operate in a storage-and-release mode, but rather are peaking facilities (including the developments characterized as run-of-river, which receive peaking flows from upstream developments).

Response: The description in the scoping document of how the Projects are operated has been revised accordingly.

Comment: American Whitewater and the Appalachian Mountain Club commented on the effects of flow diversion and dewatering of the natural river channel downstream from Ripogenus Dam and Stone Dam on aquatic habitat, river connectivity, sediment transport, water quality, recreational opportunities, and aesthetics.

Response: The NEPA document will evaluate the effects of flow diversion and dewatering of the natural river channel downstream from Ripogenus Dam and Stone Dam on the environmental and recreational resources identified by American Whitewater and the Appalachian Mountain Club. Section 4.1, *Resources Issues*, has been revised to clarify the specific resources to be analyzed.

Comment: American Whitewater and the Appalachian Mountain Club recommended that the NEPA include an analysis of the effects of the pumping operation at Millinocket Lake Storage Dam on flow releases into Millinocket Stream. The specific interest is in natural flow variability that would be beneficial to aquatic habitat and recreation, and that does not degrade water quality.

Response: The NEPA document will include an analysis of the pumping operation at Millinocket Lake Storage Dam and its effects on flow releases to Millinocket Stream. Section 4.1.2, *Water and Aquatic Resources*, has been revised accordingly.

**Water Quality**

Comment: American Whitewater and the Appalachian Mountain Club recommended that the NEPA document include an analysis of the effects of flow diversion and dewatering of the natural river channel downstream from Ripogenus Dam and Stone Dam on water quality in the West Branch. NMFS recommended that the NEPA document include an analysis of the effects of project operation on water temperature in the West Branch and mainstem Penobscot River.

Response: As indicated in section 4.1.2, *Water and Aquatic Resources*, the effects of project operation on dissolved oxygen and water temperature in the project impoundments and affected reaches of the West Branch will be evaluated in the NEPA document. This analysis will extend to the mainstem Penobscot River due to the lack of any operational effects of the downstream Medway Project No. 2666 and Mattaceunk Project No. 2520 on water quality in the mainstem Penobscot River. Section 4.1.2 has been revised accordingly.

Comment: Maine Council TU, Paul Johnson, and Robert Vadas recommended that the NEPA document include an analysis of the effects of flow release elevation at Ripogenus Dam on water temperature in the Upper Gorge and the West Branch downstream from Ripogenus Dam, including downstream from McKay Station.

Response: As indicated in section 4.1.2, *Water and Aquatic Resources*, the effects of project operation on water quality in the project impoundments and affected reaches of the West Branch will be evaluated in the NEPA document. Section 4.1.2 has been revised to clarify that the analysis in the NEPA document will include an analysis of the flow release elevation at Ripogenus Dam and its effect on water temperature in the Upper Gorge and the West Branch downstream from McKay Station.

**Fish and Aquatic Resources**

Comment: Stephen Condren commented on the effects of low flows and exposed river bottom on aquatic insects in the West Branch. Edward Spear recommended that the NEPA document include an analysis of the effects of operating the Projects (i.e., peaking and fluctuating flows) on aquatic macroinvertebrates in the West Branch. American Whitewater and the Appalachian Mountain Club recommended that the NEPA document include an analysis of the effects of flow diversion and dewatering of the natural river channel downstream from Ripogenus Dam and Stone Dam on aquatic habitat and river connectivity. Maine DIFW recommended that the NEPA document include an analysis of the effects of summer drawdowns greater than 10 feet in the Ripogenus Impoundment on macroinvertebrate abundance and diversity. Finally, Sarah Sindo commented on the effects of low-flow excursions downstream from McKay Station on crayfish and other macroinvertebrates in the West Branch.

Response: The NEPA document will include an analysis of flows and flow fluctuations in the West Branch downstream from the project dams and powerhouses on aquatic organisms, including fish populations and movement and macroinvertebrates (e.g., aquatic insects and crayfish). Section 4.1.2, *Water and Aquatic Resources*, has been revised accordingly.

Comment: Edward Spear recommended that the NEPA document include an analysis of the effects of operating the Projects on smelt abundance and downstream drift in the project impoundments and West Branch, as well as lake whitefish populations in the Ripogenus impoundment. Maine DIFW recommended that the NEPA document include an analysis of the effects of operating the Projects on smelt drift in the West Branch. Robert Vadas commented on the effects of operating the Projects on smelt drift in the West Branch.

Response: The NEPA document will include an analysis of smelt populations and drift in the project impoundments and the West Branch, as well as the lake whitefish population in the Ripogenus Impoundment. Section 4.1.2, *Water and Aquatic Resources*, has been revised accordingly.

Comment: FWS recommended that the NEPA document include an analysis of the effects of continuing to operate the Projects on water and aquatic resources, including fish migration, as well as wildlife and botanical resources in, and along, the project impoundments and the West Branch. The analysis would cover each individual development, as well as the Projects' potential indirect effects on the mainstem Penobscot River.

Response: As indicated in section 4.1.2, *Water and Aquatic Resources*, and section 4.1.3, *Wildlife and Botanical Resources*, the effects of continuing to operate the Projects on: (1) water and aquatic resources, including fish migration and movement; (2) wetlands; and (3) littoral and riparian habitat in, and along, the project impoundments and the West Branch will be included in the NEPA document. Section 4.1.3 has been revised to indicate that we intend to analyze the effects of operating the Projects on wildlife in the project area. However, as indicated in the scoping document, the NEPA review will be done in accordance with CEQ's new NEPA regulations, which, at this time, do not require an analysis of a project's indirect effects on resources affected by other development in the basin.

Comment: FWS recommended that the analysis of fish entrainment not be limited to fish populations, but also should include an analysis of the effects on food web interactions and overall ecosystem productivity.

Response: As indicated in section 4.1.2, *Water and Aquatic Resources*, the effects of continuing to operate the Projects on fish impingement and entrainment will be included in the NEPA document. However, the entrainment analysis will not include the effects on the food web and overall ecosystem productivity, because food web effects related to project operations would be difficult to distinguish from other factors. Moreover, we would be concerned with food web interaction if there were an identified

population effect, which is not established in this case. Therefore, no changes to the scoping document have been made at this time.

Comment: Maine DIFW recommended that any analysis of fish passage for sea-run species in the NEPA include an analysis of the effects of providing passage for migratory species on the establishment of invasive species in the project impoundments and the West Branch.

Response: Because providing passage at dams has the potential to allow unwanted, invasive species to access upstream habitats, which could disrupt native fish and aquatic organisms, the analysis of fish passage in the NEPA document will include consideration of introducing invasive species to habitats in the West Branch watershed. Section 4.1.2, *Water and Aquatic Resources*, has been revised accordingly.

Comment: Maine DMR recommended that the NEPA document include an analysis of the effects of operating the Projects on diadromous fish movement, passage, and habitat in the project area and the West Branch.

Response: As indicated in section 4.1.2, *Water and Aquatic Resources*, the effects of continuing to operate the Projects on diadromous fish movement and passage will be included in the NEPA document. Section 4.1.2 has been revised to clarify that the NEPA document will also consider the effects on migratory fish habitat, where appropriate.

**Terrestrial Resources**

Comment: Tom Janelle commented that without stable water levels, the large and consistent drawdowns on the water quality of Caribou Lake and changes to the shoreline will have lasting and profound effects on the wildlife in the area (e.g., establishment of plants and trees in the lake bed due to low water levels). Kathleen Houston commented on the fluctuating lake levels in Ripogenus Impoundment and the potential for ongoing and future harm to wildlife and the lake ecosystem. Ms. Houston observed that hundreds of feet of shoreline are covered in plants and trees, and that this level of succession is not the result of a 1- or 2-year drought.

Response: As indicated in section 4.1.3, *Wildlife and Botanical Species*, the effects of continuing to operate the Projects on wildlife and plant species, as well as riparian habitat will be included in the NEPA document. Section 4.1.3 has been revised to clarify that the analysis will include potential effects of the drawdowns and low lake levels on riparian areas around the Ripogenus Impoundment and wildlife dependent on those habitats.

Comment: Owen Genest commented on the ecological and biological effects of the water level fluctuations in Chesuncook Lake and Caribou Lake; specifically making it more difficult for wildlife to access water and forage on aquatic vegetation, as well as increasing the vulnerability to predators. Peter Forti commented that the steady decline of water levels over the years has not only affected recreational activities but has also affected wildlife (e.g., eagles, osprey, herons, loons and other birds that rely on the lakes for their food supply, as well as animals that rely on the lakes for drinking water). Douglas Binder commented on the effects of water level fluctuation within the lakes and associated effects on wildlife populations.

Response: As indicated in section 4.1.3, *Wildlife and Botanical Species*, the effects of continuing to operate the Projects on wildlife and plant species will be included in the NEPA document. No changes to the scoping document are necessary.

Comment: Maine DIFW identified several state endangered, threatened, and species of special concern that are likely to occur in the vicinity of the Projects, including the: (1) state endangered little brown bat, northern long-eared bat, and resident and migratory golden eagle; (2) state threatened eastern small-footed bat; (3) state special concern big brown bat, red bat, hoary bat, silver-haired bat, tri-colored bat, wood turtle, bigmouth pondsnail, and pygmy snaketail dragonfly; and (4) rare mussel species. In addition, Maine DIFW reports that the Projects' impoundments contain inland waterfowl and wading bird habitats, which provide important breeding, feeding, migration, staging, and wintering habitat for waterfowl and wading bird species, and are considered Significant Wildlife Habitat under Maine's Natural Resources Protection Act.

Response: As indicated in section 4.1.3, *Wildlife and Botanical Species*, the effects of continuing to operate the Projects on state-protected wildlife and plant species will be included in the NEPA document. Section 4.1.3 has been revised to clarify that the analysis will consider Species of Special Concern and Significant Wildlife Habitat that are listed under Maine's Natural Resources Protection Act.

**Threatened and Endangered Species**

Comment: NMFS recommended that the NEPA document include an analysis of the effects of continuing to operate the Projects on the movement, passage, and restoration/recovery of the Gulf of Maine Distinct Population Segment of the Atlantic salmon in the Penobscot River Basin.

Response: As indicated in section 4.1.4, *Threatened and Endangered Species*, the effects of continuing to operate the Projects on the Gulf of Maine Distinct Population Segment of the Atlantic salmon and its critical habitat will be included in the NEPA

document. Section 4.1.4 has been revised to clarify that the analysis will consider the movement, passage, and restoration/recovery of the species.

Comment: FWS commented on the little brown bat and the tri-colored bat within the Projects' boundaries. Both species are currently undergoing consideration for listing by FWS under the Endangered Species Act.

Response: The NEPA document will discuss the effects of the Projects on the little brown bat and the tri-colored bat. Section 4.1.3, *Wildlife and Botanical Species*, has been revised to include these two species as well as other state threatened and endangered species potentially occurring in the Project areas. If these two bat species become federally listed, they will be addressed in section 4.1.4, *Threatened and Endangered Species.*

**Recreation, Land Use, and Aesthetics**

Comment: Benjamin Koehler commented on a 10-foot waterfall in the West Branch between Quakish Lake and Dolby Pond and its significance as an aesthetic and recreational resource.

Response: The NEPA document will address the aesthetic qualities of the West Branch in the vicinity of the Projects. Section 4.1.5, *Recreation, Land Use, and Aesthetic Resources,* has been revised to include the effects of operating the Projects, including maintenance activities, on aesthetic resources.

Comment: Ryan Gerry, Alexandra Horne, Christopher Howe, Alec Jansujwicz, Benjamin Koehler, Jake Risch, and Michael Smith commented on the potential whitewater recreation opportunities, including flows, of the West Branch (i.e., the Upper Gorge and the West Branch downstream from Stone Dam) and Millinocket Stream.

Response: The NEPA document will include an analysis of whitewater recreation opportunities on the West Branch. Section 4.1.5, *Recreation, Land Use, and Aesthetics*, has been revised to include the effects of operating the Projects on the whitewater recreation potential of the Upper Gorge, the West Branch downstream from Stone Dam, and Millinocket Stream.

Comment: The Maine Bureau of Parks and Lands commented on the effects of low lake levels on boat access to Chesuncook Lake, the North Twin Impoundment (Ambajejus and South Twin Lakes), and Millinocket Lake.

Response: Changes in how the Projects are operated (i.e., lake level drawdowns) have the potential to affect recreation infrastructure, such as boat launch accessibility and navigation within individual project impoundments, which may affect recreation in the area. As indicated in section 4.1.5, *Recreation, Land Use, and Aesthetics*, the NEPA document will include an analysis of continuing to operate and maintain the Projects on project recreation facilities and their use.

Comment: Brendan Alterio commented on the effects of low lake levels on views of Mt. Katahdin.

Response: As described in section 4.1, *Resource Issues*, the NEPA document will include an analysis of lake level drawdowns and fluctuations on Ripogenus Impoundment, and any associated effects on environmental and recreational resources. Section 4.1.5, *Recreation, Land Use, and Aesthetic Resources,* has been revised to include the effects of project operation and maintenance activities on the aesthetic quality of the area.

Comment: Edward Spear recommended that the NEPA document include an analysis of the effects of continued operation of the Projects on angling opportunities and success for landlocked Atlantic salmon in the West Branch downstream from Ripogenus Dam. Robert Vadas commented on the effects of Project flows on angling success in the West Branch, including the effects of flow releases into the Upper Gorge and whitewater flow releases from McKay Station on the brook trout fishery.

Response: The NEPA document will include an analysis of continuing to operate the Projects on angling opportunities and success, especially for landlocked Atlantic salmon and brook trout. Section 4.1.5, *Recreation, Land Use, and Aesthetics*, has been revised accordingly.

**Cultural Resources**

Comment: The Maine Historic Preservation Commission commented that it was unclear in SD1 if the entire project boundary has been surveyed for architectural resources, and archaeological sites in the APE. The Maine Historic Preservation Commission recommended identification of all resources in the APEs for the Projects.

Response: Section 4.1.6, *Cultural Resources,* has been revised accordingly.

Comment: Benjamin Koehler commented that the Projects have significant effects on cultural resources.

Response: The NEPA document will include an analysis of the effects of relicensing the Projects on cultural resources. In addition, GLHA proposes to develop a Historic Properties Management Plan for each project to protect cultural resources.

**Socioeconomics**

Comment: The Penobscot Indian Nation expressed concerns with Environmental Justice regarding the continued operation of the Projects, as the Projects may disproportionately affect minority and low-income people, including Native Americans, living in the region. The Penobscot Indian Nation asked that Commission staff provide the stakeholders guidance as to Environmental Justice concerns at the Projects, as well as any recent changes in the Commission's NEPA analysis that may or may not include sections on Environmental Justice and how that analysis may relate to the Projects.

Response: We intend to use EPA's EJSCREEN tool to analyze whether there are environmental justice communities in the vicinity of the Projects. However, this analysis has not yet been completed. The scoping document has been modified to reflect the need to analyze whether such communities exist in the vicinity of the Projects, and, if so, if they are subject to disproportionately high adverse human health or environmental effects as a result of the Projects. Section 4.1, *Resource Issues*, has been revised to include a category for Socio-Economic issues, including Environmental Justice. In addition, Section 7.0, *Proposed NEPA Document Outline*, has been added to the scoping document, which includes a section for analyzing Socio-Economic and Environmental Justice issues.

Comment: The Allagash Gateway Campground recommended that the Commission's NEPA analysis include the effects of the Ripogenus Impoundment's unregulated low water levels on the economy of the surrounding area. Emelia Ferland requests that the Commission assess the effects of low water levels on Caribou Lake and Chesuncook Lake (part of the Ripogenus Impoundment) on property values. The Caribou and Chesuncook Lake Camp Owners Association and the Chesuncook Dam Camp Owners Association recommended that the NEPA document include an analysis of the effects of water level fluctuations within the Ripogenus Impoundment of property values of the residences around the impoundment.

Response: Changes in how the Projects are operated (i.e., lake level drawdowns) have the potential to affect recreation infrastructure, such as boat launch accessibility and navigation within individual project impoundments, which may affect tourism and recreation in the area. Section 4.1.7, *Socioeconomic Resources*, has been added to the scoping document, and will include a broad analysis of the potential effects of operating the Projects on local and regional economies. However, the Projects' operational effects

on the values of specific, individual properties, will not be addressed, as such estimates could be construed as "damages," which the Commission cannot adjudicate under the FPA.

Comment: The Penobscot Indian Nation commented on the need to consider existing socioeconomic conditions in the area around the Projects as part of the environmental review process.

Response: The NEPA document will include a discussion of the past and present socioeconomic conditions in the vicinity of the Projects. Section 4.1, *Resource issues*, has been revised to include a section for socio-economic issues. Also, section 7.0, *Proposed NEPA Document Outline*, has also been added to the scoping document, which includes a section for Socioeconomic Resources.

**Developmental Resources**

Comment: Edward Spear stated that the Projects were initially licensed to provide power to the paper mills in the area, and that since the closure of the paper mills, GLHA has used the West Branch system [*including the Ripogenus and Penobscot Mills Projects*] as a spinning reserve power source. Mr. Spear contends that this operation affects the fisheries in the system.

Response: The NEPA document will include an evaluation of the proposed action, as well as alternatives to the proposed action, including current operations and any operational alternatives developed based on the outcome of any studies conducted to support relicensing the projects. No changes to the scoping document are necessary.

## 3.0 PROPOSED ACTIONS AND ALTERNATIVES

In accordance with NEPA, the environmental analysis will consider the following alternatives, at a minimum: (1) the no-action alternative; (2) the applicant's proposed actions; and (3) alternatives to the proposed actions.

### 3.1 NO-ACTION ALTERNATIVE

Under the no-action alternative, the Ripogenus Project and Penobscot Mills Project would continue to operate as required by their current project licenses (i.e., there would be no change to the existing environment). No new environmental protection, mitigation, or enhancement measures would be implemented. We use this alternative to establish baseline environmental conditions for comparison with other alternatives.

### 3.1.1 Project Facilities

*RIPOGENUS PROJECT*

The Ripogenus Project is located about 21 river miles (RM) upstream of the Penobscot Mills Project on the West Branch of the Penobscot River (West Branch), which flows into Ambajejus Lake (part of the Penobscot Mills Project's North Twin Development). The project generally consists of a dam, reservoir, intake structure, a tunnel and penstocks, powerhouse with generation equipment, and a transmission line (figure 2).[12]

Ripogenus, Caribou, and Chesuncook Lakes and Black, Brandy, and Moose Ponds constitute the Ripogenus impoundment created by Ripogenus Dam. The impoundment is about 20.8 miles long and has a surface area of approximately 29,270 acres at the normal full pond elevation of 941.59 feet United States Geological Survey (USGS) datum.[13] The impoundment's mean depth is 35.8 feet, and usable storage is about 688,705 acre-feet, with a maximum drawdown of 44 feet (to elevation 897.59 feet).[14] Ripogenus Dam, a 795-foot-long concrete and earth-filled structure, is located at the outlet of Ripogenus Lake. The dam, which crosses the West Branch in a north-south direction, includes two concrete ogee[15] spillway sections totaling about 480 feet in length, a 37-foot-long intake section, a 178-foot-long gated sluice section, and a 100-foot-long earth section.

Water flows from Ripogenus impoundment through a concrete intake structure, which is protected by trash racks with 2-5/8 inch clear spacing. The intake structure connects to a 16-foot-diameter concrete-lined tunnel that is approximately 3,850 feet long and connects to three penstocks that lead to the powerhouse (McKay Station). Flows diverted to the tunnel, penstocks, and powerhouse bypass a 0.75-mile-long river reach (Upper Gorge) of the West Branch.

[12] This SD2 provides a summary of the Ripogenus Project and the Penobscot Mills Project facilities. The Ripogenus and Penobscot Mills Projects are described in greater detail in section 4.3, *Existing Project Facilities*, of the PAD.

[13] Unless otherwise noted, all elevations cited in this SD1 are in USGS datum.

[14] The Ripogenus Project also includes Umbazooksus Lake, which is a 1,600-acre former storage impoundment that is located within the project boundary. In 1998, the storage and release operations were discontinued so the current flow regime is run-of-river. Umbazooksus Lake, therefore, provides no storage capacity to the Ripogenus Project.

[15] An ogee-shaped spillway contains a controlled weir and is S-shaped in profile.

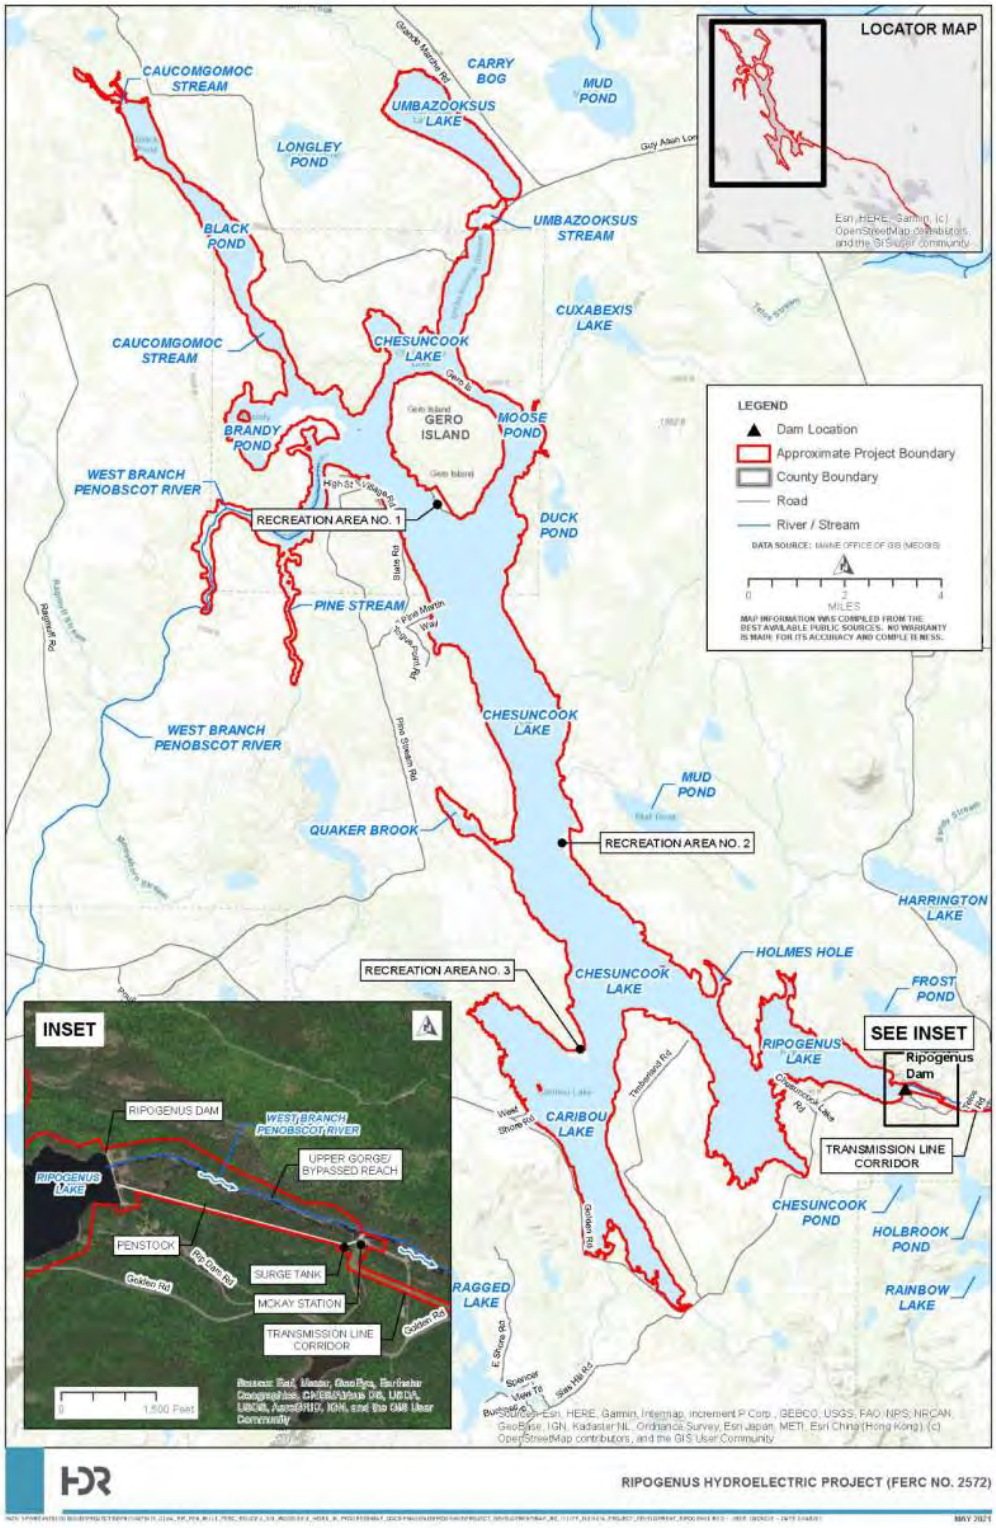

Figure 2. Ripogenus Hydroelectric Project facilities (source: PAD).

The 130-foot-long by 45-foot-wide powerhouse contains three vertical Francis-type turbines, each connected to a generator. The rated capacity of the three turbines is 38.6 MW, and the rated capacity of the three generators is 37.5 MW. Flow from the powerhouse is conveyed back to the West Branch via a 50-foot-long excavated bedrock tailrace.

The power generated at the Ripogenus Project is transmitted to the electric grid via three transformers and transmission lines that start at the substation at McKay Station and extend about 29.4 miles to GLHA's Millinocket Substation #4 (part of the Penobscot Mills Project). An additional 0.75-mile-long transmission line extends from the McKay Substation to Ripogenus Dam to supply backup power to the gate operators and to Ripogenus Village.

The Ripogenus Project also contains one utility-scale battery energy storage site that is part of a Battery Energy Storage System at the Projects (*see* Battery Energy Storage System description for the Penobscot Mills Project).

*PENOBSCOT MILLS PROJECT*

The Penobscot Mills Project consists of four hydropower developments (North Twin, Millinocket, Dolby, and East Millinocket; located between RM 15 and RM 2 on the West Branch of the Penobscot River) and one storage development (Millinocket Lake Storage Development; located on Millinocket Stream) (figure 3).[16] The primary features of the Penobscot Mills Project include five dams, five impoundments, and four powerhouses. The total installed capacity of the project is 67.9 MW.

The North Twin Impoundment is at the upstream end of the Penobscot Mills Project and receives flow from the Ripogenus Project (figure 3). Releases from the North Twin Development pass through three other developments and associated generation facilities of the Penobscot Mills Project, including the Millinocket, Dolby, and East Millinocket Developments. The Millinocket Lake Storage Development includes a pumping station through which water can be pumped to Ambajejus Lake (within the North Twin impoundment). Otherwise, water is discharged to Millinocket Stream, which enters the West Branch at Shad Pond (downstream from the Millinocket Development; *see* figure 6 below) and passes through the Dolby and East Millinocket Developments.

[16] *See* n. 12 *supra*.

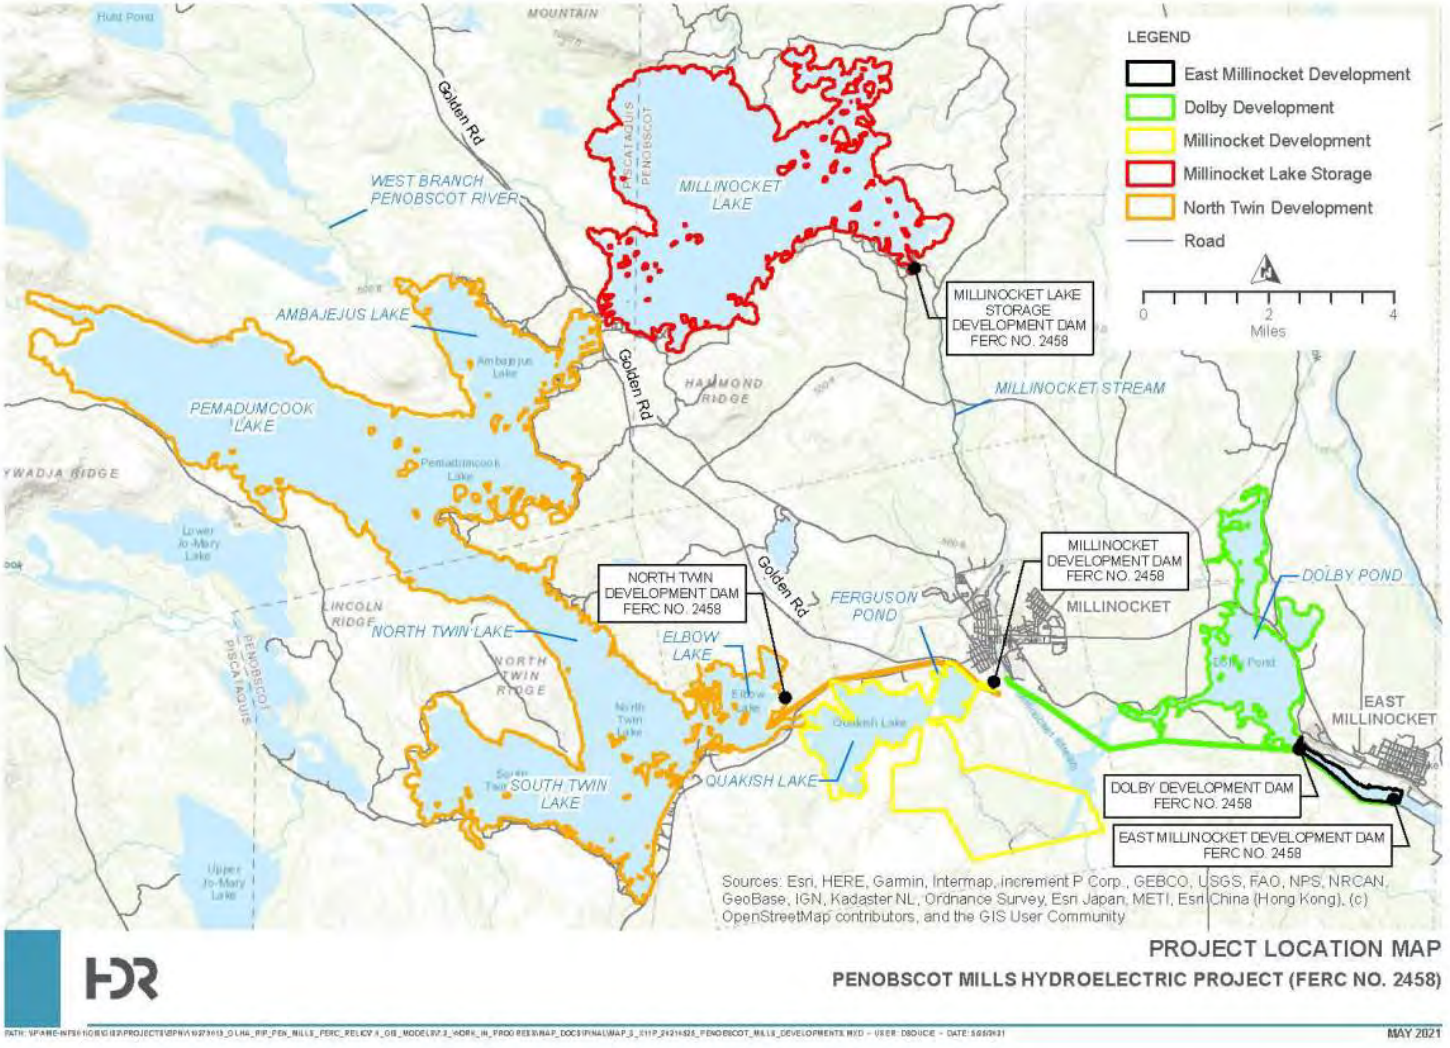

Figure 3. Penobscot Mills Hydroelectric Project Location Map (source: PAD).

**Millinocket Lake Storage Development (figure 4)** – Millinocket Lake has a normal full pond elevation of 480.0 feet, with a surface area of 8,640 acres. The lake has a mean depth of 23.6 feet. Usable storage of the lake is 45,370 acre-feet, with a 6.2-foot drawdown. Millinocket Lake is impounded by a 635-foot-long, concrete and earth-filled dam located on Millinocket Stream, at the outlet of Millinocket Lake. Millinocket Lake Storage Dam includes a 19-foot-long spillway section and an adjacent 58-foot-long gated section that contains four lift gates and one log sluice gate. The dam is located approximately 7.8 miles upstream of the Millinocket Development tailrace. The development's pumping station, which contains two pumps, is located on the west side of Millinocket Lake, about 6.2 miles from Millinocket Lake Storage Dam. Water is conveyed from the pumping station through two 544-foot-long, 4-foot, 6-inch-diameter steel pipes, which is then discharged to Ambajejus Lake through an outlet structure.

**North Twin Development (figure 5)** – The North Twin impoundment includes Elbow, South Twin, North Twin, Pemadumcook, and Ambajejus Lakes. The impoundment is about 11.8 miles long and has a surface area of approximately 17,790 acres at the normal full pond elevation of 491.92 feet. The impoundment's mean depth is 27.7 feet, and its usable storage is about 344,355 acre-feet with a drawdown of 22 feet. The North Twin impoundment is formed by North Twin Dam, which is a 1,051-foot-long concrete and earth-filled structure located at the outlet of Elbow Lake. The dam, which crosses the West Branch from southeast-northwest, includes a 500-foot-long, earthen dike; a 114-foot-wide intake structure and powerhouse; a 34-foot-wide fishway[17] section with two gated log sluices; a 117-foot-long Tainter gate section; and a 286-foot-long earthen embankment. In addition to the dam, there are six dikes, totaling 2,530 feet in length, retaining water.

Water flows from the North Twin impoundment through an intake structure to the powerhouse. The intake contains nine water passages, each 8 feet wide by 13 feet high and equipped with a steel gate to control the flow of water to the turbines. The intake is protected by trash racks with 2-5/8-inch clear bar spacing. The trash racks are cleaned with a trash rake. The 50-foot by 114-foot powerhouse, which is integral with, and located immediately downstream from the intake, contains two vertical fix-blade turbines and one vertical Kaplan turbine, each connected to a generator. The rated capacity of the three turbines is 7.0125 MW and the rated capacity of the three generators is 9.84 MW. Water exits the powerhouse through six tailrace bays and flows through a 104-foot-wide tailrace back to the West Branch.

[17] Flow to the 98-foot-long pool and weir fishway is controlled by three gates located at different depths upstream of the fishway. The upstream fishway provides passage for resident fish species (e.g., landlocked salmon).

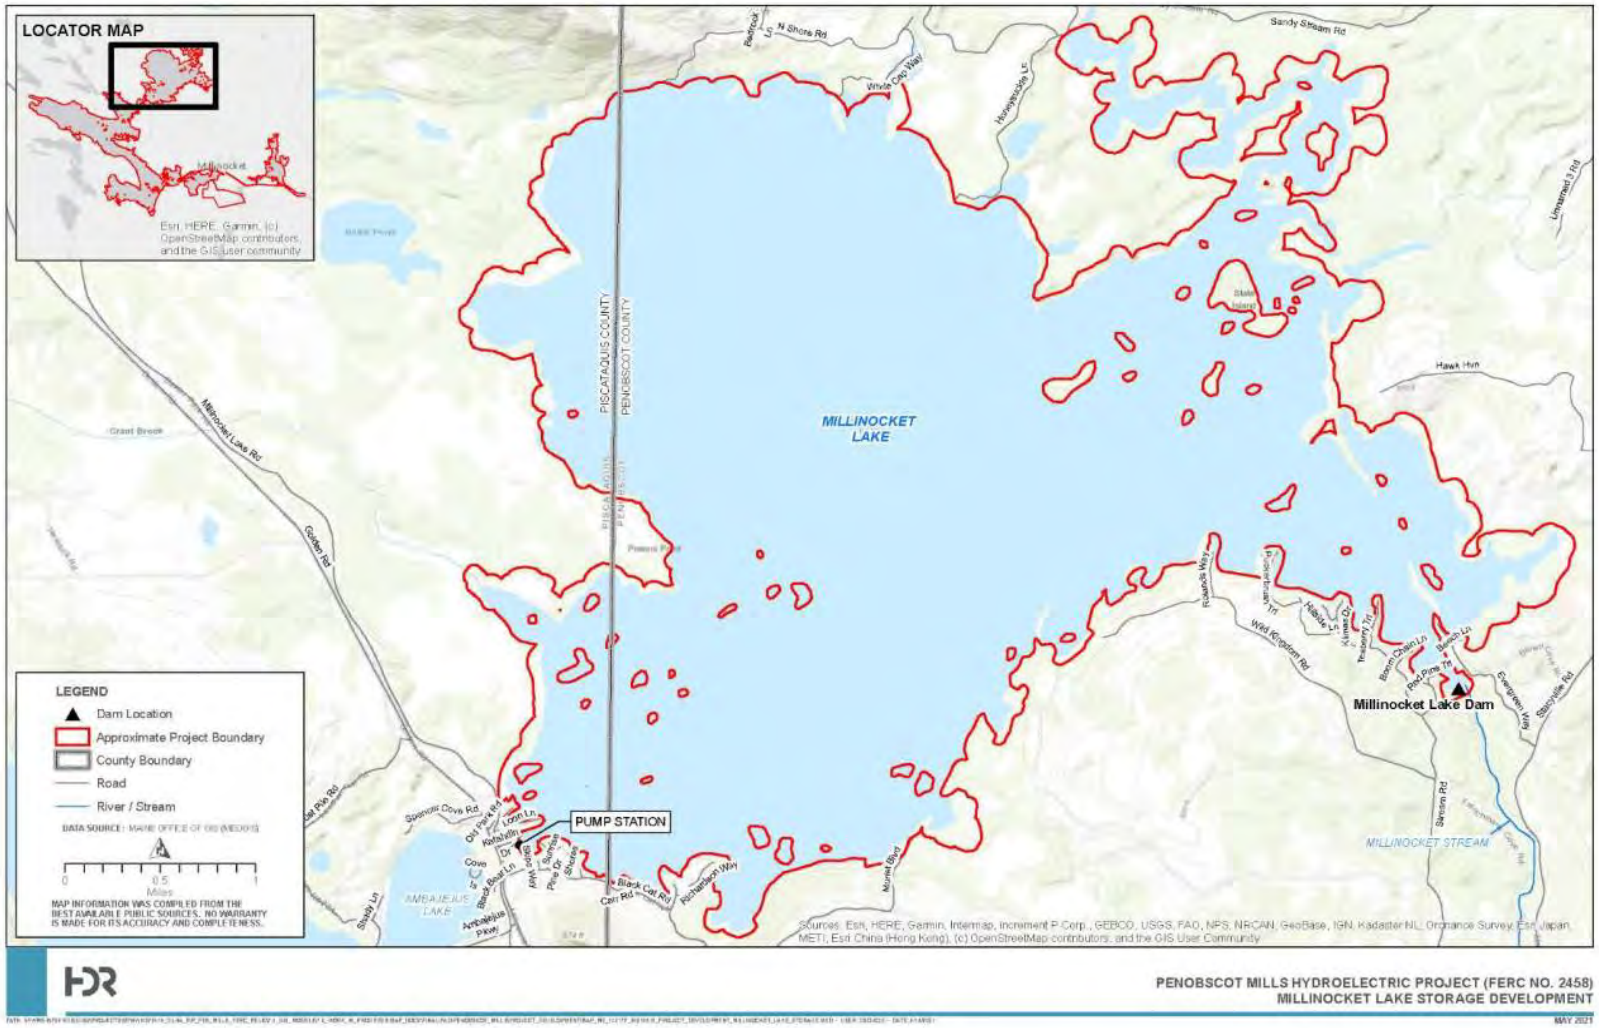

Figure 4. Millinocket Lake Storage Development facilities (source: PAD).

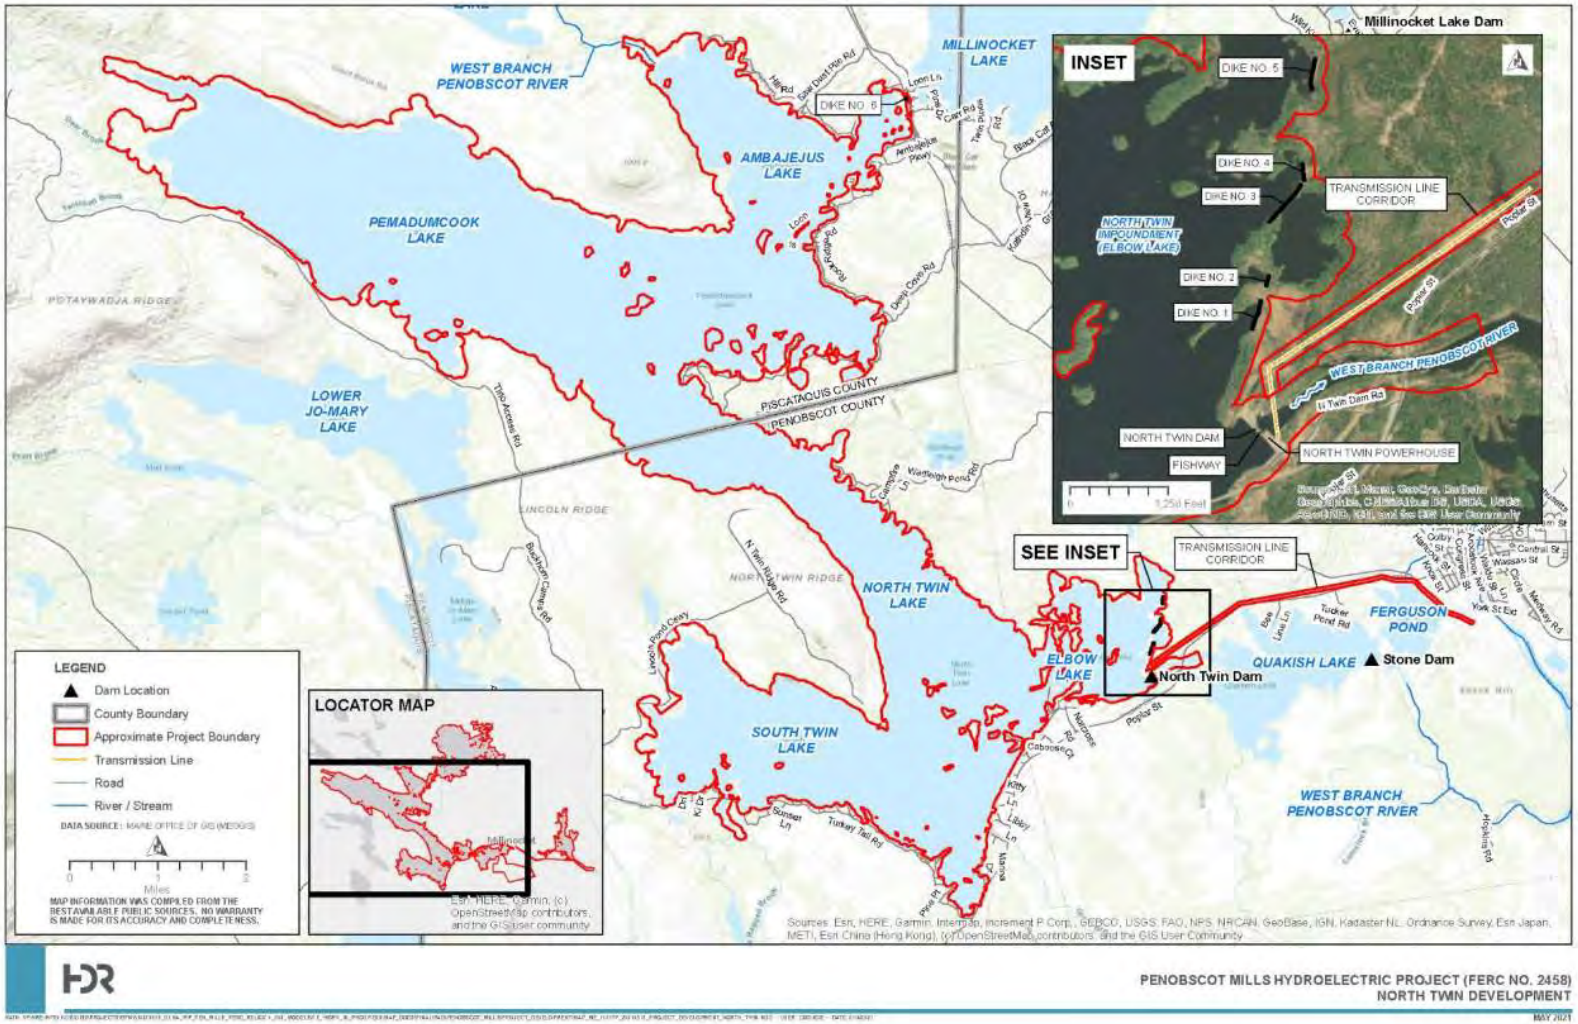

Figure 5. North Twin Development facilities (source: PAD).

The power generated by the North Twin Development is transmitted to the grid via an adjacent substation that contains six transformers and a 4.2-mile-long transmission line that extends to GLHA's Substation #4 located at the former Millinocket Mill.

**Millinocket Development (figure 6)** – The impoundment for the Millinocket Development consists of Quakish Lake and Ferguson Pond. The 8,600-foot-long Quakish Lake has a surface area of 1,344 acres at a normal full pond elevation of 458.7 feet. Quakish Lake and Ferguson Pond provide negligible storage. Stone Dam, a 1,262-foot-long, concrete structure, is located at the outlet of Quakish Lake. The dam directs water into the western canal, and consists of: (1) a 300-foot-long overflow spillway section with no flashboards; (2) a 358-foot-long spillway section with 30-inch-high flashboards; (3) a 52-foot-wide waste gate; (4) a 428-feet, 5-inch-long spillway with a 2-foot, 9-inch-high rubber, inflatable dam; and (5) a 124-foot-long gatehouse. In addition to Stone Dam, there are three dikes, with a total length of 1,854 feet, located along the north shore of Quakish Lake that retain water.

The gatehouse is integral with Stone Dam and is used to regulate flow into the 150-foot-wide by 1,400-foot-long western canal. The western canal conveys water from Quakish Lake to Ferguson Pond. Five earthen dikes, with a total length of 3,915 feet, are located along the perimeter of Ferguson Pond and are used to confine the area impounded by Ferguson Pond. From Ferguson Pond, water enters the 150-foot-wide by 1,300-foot-long eastern canal which conveys water from Ferguson Pond to an intake structure.

The intake structure contains seven gates. Six gates control flow into six 1,007-foot-long, 10-foot-diameter penstocks that lead to turbine-generator units in the 'Grinder Room.' The remaining gate controls flow into a 1024-foot-long, 11-foot-diameter penstock that leads to turbine-generator units in the 'Generator Room.' The 10-foot-diameter penstocks are protected by trash racks with 2-7/8-inch clear bar spacing, and the 11-foot-diameter penstock is protected by trash racks with 2-1/2-inch clear bar spacing. The 174.5-foot-wide by 210-foot-long Grinder Room contains five horizontal Francis turbine-generator units (Units 1, 3, 4, 5, and 6)[18] and the 52-foot-wide by 122-foot-long Generator Room contains two horizontal Francis turbine-generator units (Units 7 and 8). The rated capacity of the seven turbines is 37.3748 MW, and the rated capacity of the seven generators is 38.64 MW. Water exits the turbines through seven, 25-foot-wide tailrace bays that discharge directly to ***Millinocket Stream and then flows downstream into Shad Pond and*** the West Branch.

[18] The Grinder Room also contains an inoperable turbine-generator unit (Unit 2), which does not contribute to the development's rated capacity.

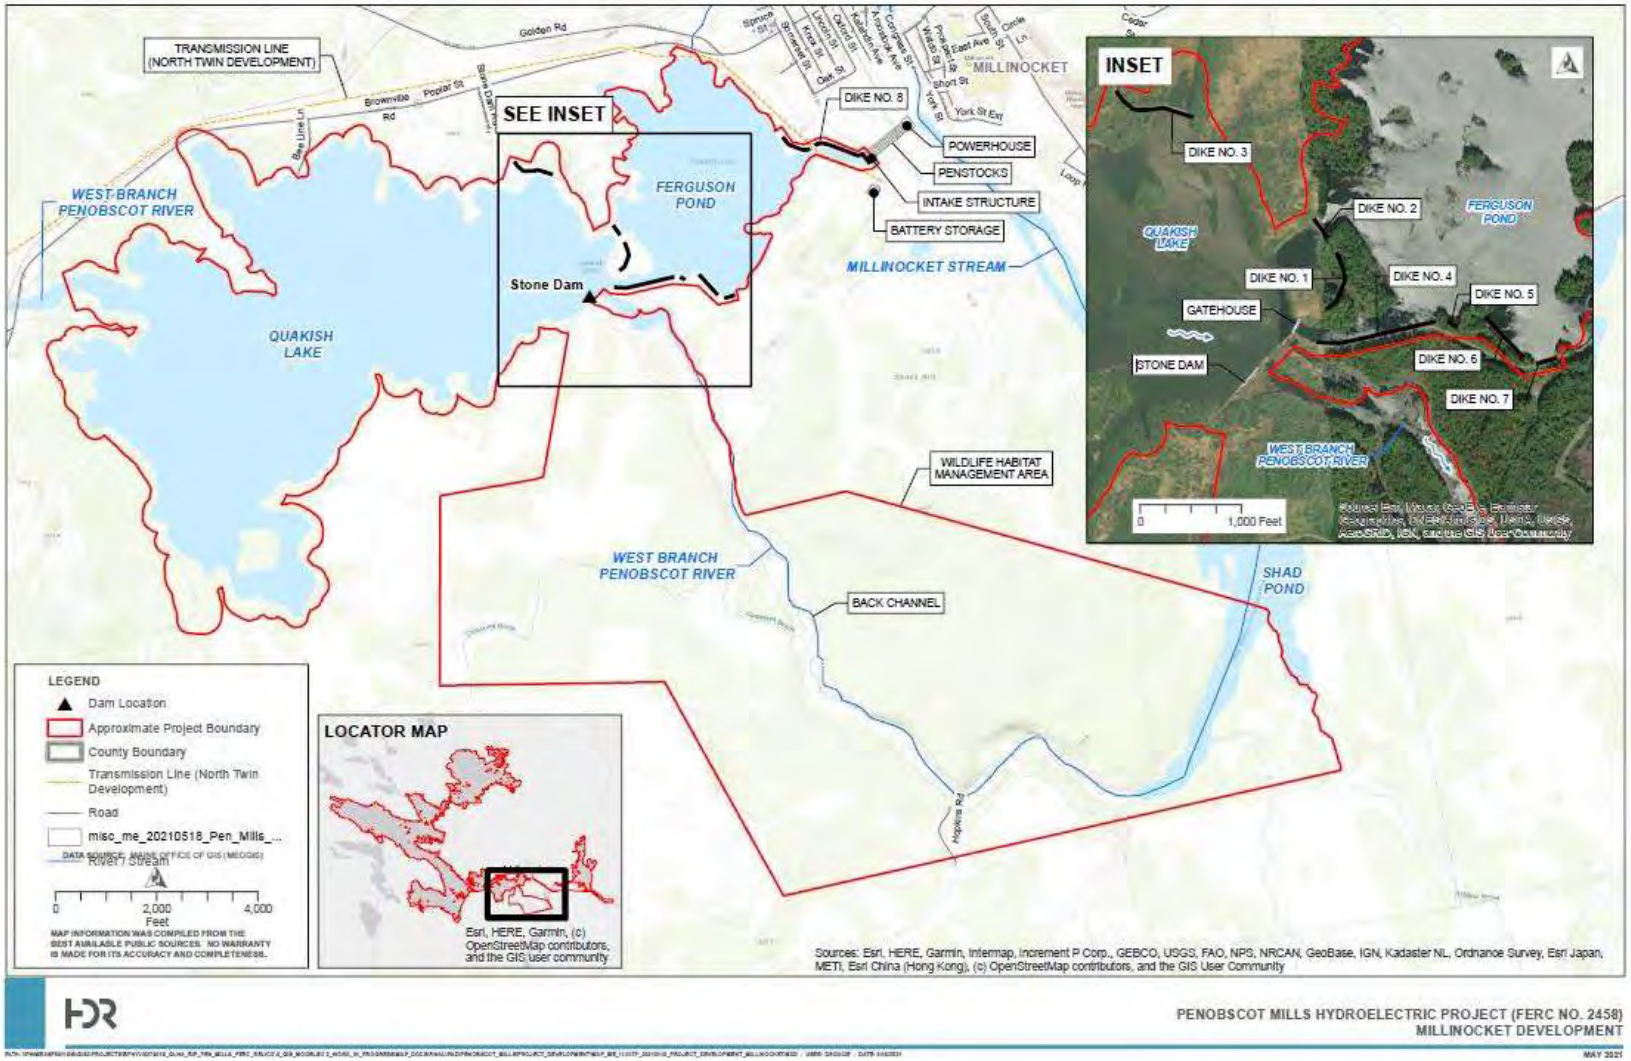

Figure 6. Millinocket Development facilities (source: PAD).

Power generated from Units 3, 4, 5, 6, and 7 is transmitted across Millinocket Stream via a 300-foot-long transmission line to a transformer in GLHA's Substation #1. Power generated from Units 1 and 8 is also transmitted across Millinocket Stream via a 300-foot-long transmission line to a second transformer in Substation #1.

**Dolby Development (figure 7)** – The 4.2-mile-long Dolby Pond has a surface area of 2,048 acres at a normal full pond elevation of 336.2 feet. Dolby Pond provides negligible storage. The 1,395-foot-long Dolby Dam is a concrete and earth-filled structure located at the outlet of Dolby Pond. The dam, which crosses the West Branch in a generally southwest-northwest direction, includes a 27-foot-long concrete abutment; four spillway sections with a total length of 521 feet; two 6-foot-long abutments; a 76-foot-wide waste gate; a 209-foot-wide intake with an integral powerhouse; and two contiguous earthen dikes, measuring 300 feet long and 250 feet long.

Water is withdrawn from Dolby Pond through a 23-foot-wide by 209-foot-long concrete intake structure with nine openings. Each opening is equipped with a headgate to control the flow of water to the turbines. Eight sets of trash racks, having a total length of 174 feet, extend across the upstream side of the intake. The trash racks for bays 2 through 4 have a clear bar spacing of 1-5/8 inches, and the trash racks for bays 5 through 8 have a clear bar spacing of 2-5/8 inches. The gate operators and trash rakes for bays 5 through 8 are housed in a 23-foot-wide by 121-foot-long concrete block building. Water flows from the intake to a 115-foot-wide by 167-foot-long powerhouse that houses four operable turbine-generator units (Units 5, 6, 7, and 8).[19] Three of the operable turbines are Inclined Kaplan units and one is a Fixed Blade unit, each connected to generators. The rated capacity of the four turbines is 17.049 MW, and the rated capacity of the four generators is 17.098 MW. Water exits the turbines through four tailrace bays and flows into a 189-foot-wide tailrace.

The power generated by the Dolby Development is transmitted to the grid via an adjacent substation that contains two transformers and a 2-mile-long transmission line that extends to GLHA's Substation #5 ***(also referred to as the Powersville Substation) located adjacent to the East Millinocket Development. Additionally, a second transmission line extends approximately 5 miles from the Dolby Substation to the former Millinocket Mill, but is currently out-of-service***.

[19] Units 1, 2, 3, and 4 in the Dolby Powerhouse are currently out-of-service, and do not contribute to the development's rated capacity.

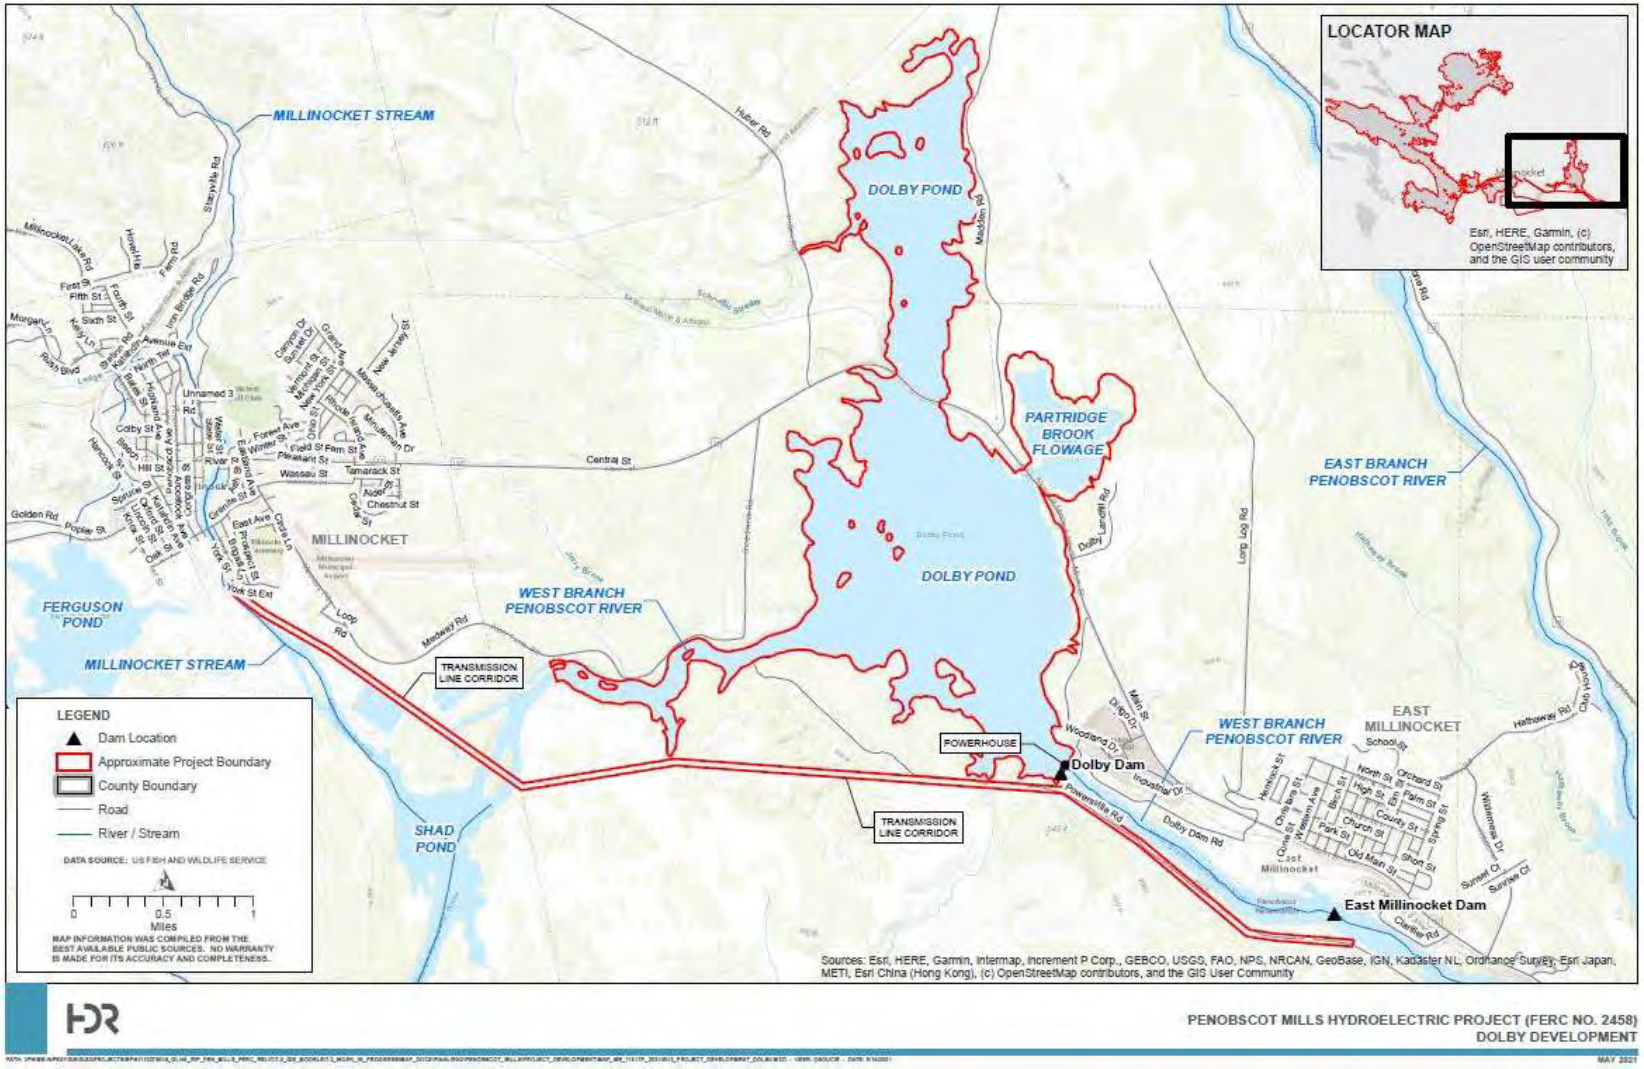

Figure 7. Dolby Development facilities (source: PAD).

**East Millinocket Development (figure 8)** – The East Millinocket Development is located at the former East Millinocket Mill, about 1.7 miles upstream of Black Bear Hydro Partners, LLC's Medway Hydroelectric Project No. 2666. The 1.9-mile-long East Millinocket impoundment extends upstream to the tailwater of the Dolby Development. The impoundment has a surface area of 128 acres at a normal full pond elevation of 287.2 feet and has negligible storage. The 717.5-foot-long East Millinocket Dam, which crosses the West Branch in a generally east-west direction, consists of a 116-foot-long earth embankment; a 212-foot-long spillway section; a 59-foot-wide waste gate; a 154-foot-long spillway section; a 7-foot-wide timber crib section; a 23-foot-wide sluice gate; and a 146.5-foot-wide intake structure integral with the powerhouse.

Water from the East Millinocket impoundment flows through a 146.5-foot-long by 54-foot-wide intake structure, containing 12, 9-foot by 11-foot gate openings. Each of 12 gate openings are equipped with a steel headgate connected to a hand-operated gate hoist that controls the flow of water into the intake. The intake is protected by trash racks that have a 1-1/4-inch clear bar spacing. From the intake, water flows into to six covered flumes in a 56-foot-wide by 146.5-foot-wide powerhouse. Each flume contains a horizontal Francis turbine connected to a generator. The rated capacity of the six turbines is 6.975 MW and the rated capacity of the six generators is 9.952 MW. Water exits the powerhouse and flows through a 1,050-foot-long tailrace (average width of 110 feet) to the West Branch.

The power generated by the East Millinocket Development is transmitted to the grid via two 6,900-volt buses, which are connected to a transformer that is part of Substation #3 located at the former East Millinocket Mill. From the transformer, power is transmitted to Substation #5 ***(also referred to as the Powersville Substation)*** via a ***2,000-foot-long*** transmission line.

**Battery Energy Storage System** – The Projects include two utility-scale battery energy storage sites that operate as a single Battery Energy Storage System. One of the battery storage sites is located at the Powersville Substation (within the transmission right-of-way for the Dolby and East Millinocket Developments). This battery storage site is sized at a capacity of 10 MW with a 2-hour duration (20 MWh total capacity). The second battery storage site is located within the Ripogenus Project's 115-kV (200-foot-wide) transmission line right-of-way adjacent to the Millinocket Substation #4 (partially within the Penobscot Mills Project boundary and partially within the Ripogenus Project boundary). This battery storage site is also sized at a capacity of 10 MW with a 2-hour duration (20 megawatt hours [MWh] total capacity). The Battery Energy Storage System has a total capacity of 20 MW for up to 2 hours (40 MWh total capacity).

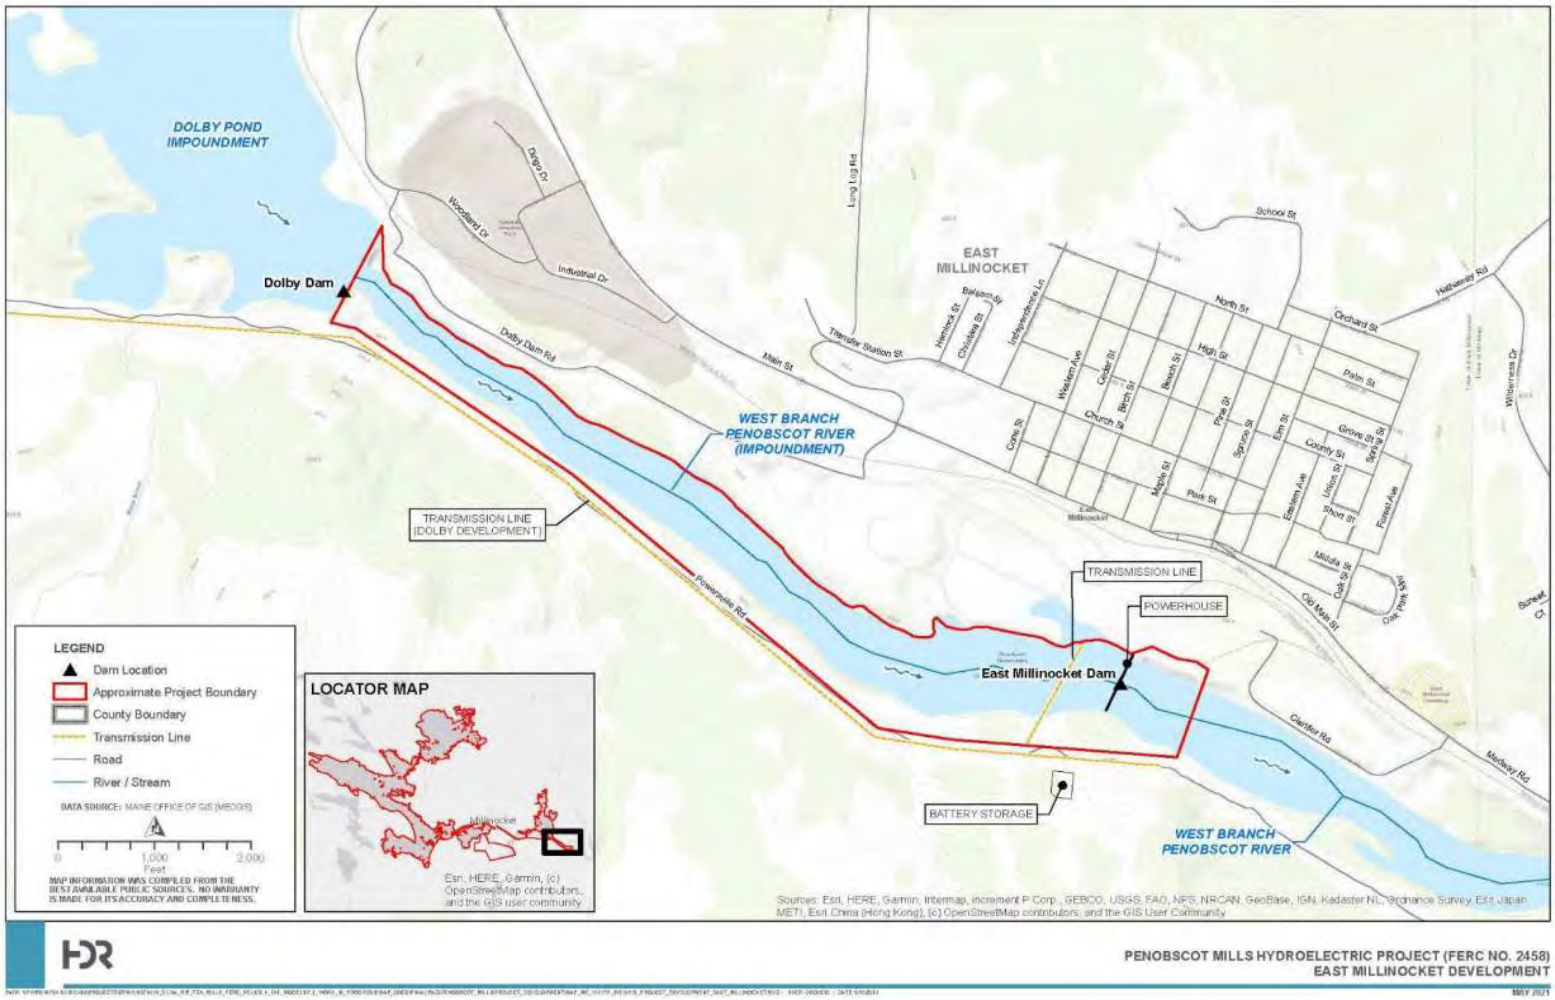

Figure 8. East Millinocket Development facilities (source: PAD).

### 3.1.2 Recreation Facilities

*RIPOGENUS PROJECT*

Ripogenus Project recreation facilities consist of a boat launch (Chesuncook Point Boat Launch), a boat put-in (Caribou Lake Put-In), 12 campsites (Chesuncook Lake Remote Campsites-10; Umbazooksus Stream Campsites-2), rafting put-in facilities (McKay Station Rafting Put-In Site), and a 0.75-mile-long trail (Upper Gorge Trail).

*PENOBSCOT MILLS PROJECT*

Penobscot Mills Project recreation facilities consist of six boat launches. The Millinockett Lake Public Boat Launch is located at the Millinocket Lake Storage Development. The Ambajejus Lake Boat Launch and South Twin Lake (Partridge Cove) Boat Launch are located at the North Twin Development. The Green Bridge Boat Launch is located ***downstream of North Twin Dam on the West Branch and within the Penobscot Mills Project boundary. It provides boating access both downstream to Quakish Lake (Millinocket impoundment) and upstream to North Twin Dam***. The Dead Man's Curve Boat Launch and Dolby Pond (Flowage) Boat Launch are located at the Dolby Development.

### 3.1.3 Project Operation

*RIPOGENUS PROJECT*

The Ripogenus Project is operated ***in accordance with its existing license,*** with an annual seasonal drawdown that allows for management of water levels and flows downstream of the project. The normal full pond elevation of the Ripogenus impoundment is 941.6 feet, with a maximum drawdown of 44 feet (based on operational limitations of the project). During normal operation and normal inflow years, the Ripogenus impoundment elevation is ***maintained at a target elevation of*** 941.6 feet during the summer months and is gradually drawn down starting in the fall, with a target low elevation of 913.6 feet by late winter, in anticipation of spring thaw and high flows. This operation results in a target seasonal drawdown of 28 feet. In the spring, the Ripogenus impoundment elevation rises based on inflows from the upstream Storage Project No. 2634, spring thaw, and precipitation, with the goal of reaching 941.6 feet by late spring. In coordination with the upstream Storage Project and the downstream Penobscot Mills Project, Ripogenus Project operators balance downstream flows and water levels to support flood control, public safety, dam safety, supplemental flows during seasonal low-flow periods, fish spawning and migration, recreation and whitewater boating, water quality, and generation needs.

GLHA also provides a minimum flow of 100 cubic feet per second (cfs) through sluice gates into the ***dewatered section of the West Branch downstream from Ripogenus Dam*** (Upper Gorge) from July 1 through September 30 and 12 cfs through leakage from Ripogenus Dam from October 1 through June 30. In addition, the project provides seasonally variable minimum flows downstream of McKay Station into the West Branch, according to the schedule in table 1, to facilitate drawdown of the North Twin impoundment, protect landlocked salmon spawning, and provide whitewater recreation flows. During failure of the generating units, the project releases 400 cfs.

Table 1. Minimum flows released from McKay Station into the West Branch. (Source: PAD).

| Date range | Minimum flow released |
|---|---|
| **Facilitate North Twin impoundment drawdown** | |
| September 16 through October 14 | 1,000 cfs |
| **Landlocked salmon flows** | |
| October 15 through November 15 | At least 1,422 cfs, or inflow, but not less than 1,300 cfs at any time.[a] |
| November 16 through June 7 | Greater than 1,422 cfs.[a] |
| **Whitewater recreation flows** | |
| May 1 through September 15 (8:30 AM - 5:00 PM) | **Normal hydrologic year:**<br>2,300 cfs on Saturdays and Sundays<br>2,200 cfs on Mondays and Fridays<br>2,000 cfs on Tuesdays through Thursdays<br>**Wet or dry hydrologic year:**<br>2,200 cfs on Saturdays and Sundays<br>2,000 cfs on Mondays and Fridays<br>1,800 cfs on Tuesdays through Thursdays |
| September 16 to October 1 (8:30 AM - 5:00 PM) | **Normal hydrologic year:**<br>2,300 cfs on Saturdays and Sundays<br>**Wet or dry hydrologic year:**<br>2,200 cfs on Saturdays and Sundays |
| June 8 to October 14 (5:00 PM - 8:30 AM) | 1,000 cfs |

[a] Actual flows are established each year in consultation with FWS and Maine DIFW.

GLHA also uses the Ripogenus Project to provide flows that are diverted to the Holbrook Side Channel from the West Branch.[20] Two pipes are used for this purpose. One is equipped with a valve that can be opened or closed to increase or reduce flows from the West Branch into the channel; the other has no valve to control flow. Flows from the channel re-enter the West Branch about 1,000 feet downstream from the pipes. Flows into the channel range from about 35 cfs to 65 cfs during normal operating conditions, depending on the amount of flow in the West Branch. On about June 1, GLHA closes the valve to reduce flow into the channel to enhance conditions for landlocked salmon and brook trout fry emergence and production. On about October 15, GLHA opens the valve to increase flow into the channel to enhance conditions for landlocked salmon and brook trout spawning.

*PENOBSCOT MILLS PROJECT*

The five developments that compose the Penobscot Mills Project are operated as an integrated system, primarily making use of flows received from the Ripogenus Project. The two ***storage*** developments (Millinocket Lake Storage and North Twin) are located upstream of the run-of-***release*** developments (Millinocket, Dolby, and East Millinocket). The North Twin impoundment receives flow from the Ripogenus Project. Flow from the Millinocket Lake Storage Development is either pumped into Ambajejus Lake (part of the North Twin impoundment) or flows down Millinocket Stream and enters the West Branch downstream from the Millinocket Development.

**Millinocket Lake Storage Development** – GLHA operates the Millinocket Lake Storage Development solely as a storage development, with no hydropower facilities. The development is operated as part of the larger West Branch system to manage flows and water levels within the West Branch and downstream in the Mainstem Penobscot River. GLHA maintains the water level in Millinocket Lake between elevations 470.0 feet and 480.0 feet (normal full pond elevation) by either pumping water via the development's pumping station to the North Twin impoundment (typically to maintain required impoundment levels within the North twin impoundment), or by releasing water into Millinocket Stream. In addition, GLHA releases a minimum flow of 60 cfs from Millinocket Lake into Millinocket Stream from May 1 through October 15, and a minimum flow of 60 cfs or inflow, whichever is less, from October 16 through April 30.

**North Twin Development** – Consistent with the operation of the Millinocket Lake Storage Development and the Ripogenus Project, the North Twin Development is

[20] The Holbrook Side Channel is a 1,400-foot-long channel located adjacent to the West Branch approximately 1.7 RM downstream from Ripogenus Dam.

operated to support flow management and water levels in the West Branch and the mainstem Penobscot River. The North Twin Development operates as a ***storage*** facility, with a normal full pond elevation of 491.92 feet. Pursuant to the current license, GLHA maintains the North Twin impoundment above elevation 488.42 feet (within 3.5 feet from normal full pond). From October 15 to the start of the spring freshet season, the impoundment elevation is gradually drawn down to an elevation of 479.42 feet (12 feet below normal full pond). However, during periods of high inflows, GLHA may use more than 12 feet of storage in the North Twin impoundment. From ice out to August 22, the impoundment is refilled and is maintained within plus or minus 0.5 foot of a target elevation of 490.42 feet (or within 1.5 feet from normal full pond elevation).

In addition to maintaining impoundment levels, GLHA releases a minimum flow of 3,000 cfs from the North Twin Development from August 22 through October 15, provided the impoundment elevation exceeds 488.42 feet. If the 488.42-foot elevation is not met, GLHA releases a minimum flow of 2,000 cfs from the North Twin Development to meet the 2,000-cfs minimum flow requirement at Shad Pond (located downstream from the Millinocket and Millinocket Lake Storage Developments).

The North Twin Development is equipped with a pool-and-weir fishway. GLHA maintains a stable impoundment elevation from May 1 through August 22 for recreation purposes, which also provides a suitable impoundment elevation for the fishway exit. In addition, GLHA provides an attraction flow of 3.5 cfs through an 8-inch-diamater gravity pipe that extends from the dam to the fishway entrance.

**Millinocket, Dolby, and East Millinocket Developments** – GLHA operates the Millinocket, Dolby, and East Millinocket Developments ***as*** run-of-***release facilities***, with typical impoundment fluctuations of 1 foot or less from the top of the flashboards when installed or crest of dam without flashboards. In addition, GLHA releases a minimum flow of 2,000 cfs through each development to the West Branch, as measured downstream from Shad Pond. ***The developments' generation*** and minimum flow ***releases*** are accomplished through use of the developments' turbines. If use of the turbines is not possible, GLHA uses the inflatable, rubber dam at Stone Dam at the Millinocket Development and waste gates at the Dolby and East Millinocket Development to support run-of-river operations.

**Battery Energy Storage System** – In 2020, GLHA installed a utility-scale Battery Energy Storage System at the Projects. One battery storage site is located at the Millinocket Substation #4 and the other is located the Powersville Substation. The Battery Energy Storage System is connected to the Project's transmission lines and collects power from the Projects at 34.5 kV and delivers it to the grid at 115 kV. The two battery storage sites can be isolated from the substations using breakers and switches, if

necessary. The system only charges from the hydroelectric facilities, and not from the grid. The system has not, and would not, change how the Projects are operated.

### 3.1.4 Proposed Environmental Measures

GLHA proposes to continue to operate and maintain the Ripogenus Project and the Penobscot Mills Project as required by their current licenses. GLHA does not propose any new development or changes in project operation. The environmental measures that are currently proposed by GLHA are described below.

**Aquatic Resources**

- Continue to provide seasonally variable minimum flows from Ripogenus Dam into Upper Gorge and from McKay Station into the West Branch as described above in table 1.

- Continue to provide flows to the Holbrook Side Channel for landlocked salmon and brook trout spawning and rearing as describe above in table 1.

- Continue to provide the seasonal minimum flows described above from Millinocket Lake Storage Dam into Millinocket Stream.

- Continue to provide the minimum flows described above from North Twin Dam, as well as the Millinocket, Dolby, and East Millinocket Developments to the West Branch.

**Wildlife and Botanical Resources**

- Continue to deploy artificial nesting platforms for the Common Loon and other aquatic birds in the Ripogenus impoundment.

- Continue to implement and maintain the wildlife enhancement measures included in the Wildlife management Plan required by Article 412 of the current license for the Wildlife Management Area located adjacent to the ***West Branch*** downstream from Stone Dam.

**Recreation Resources**

- Continue to operate and maintain the 11 recreation sites described above for the Projects.

- Continue to collect recreation use information every 6 years for the project recreation sites.

- Continue to provide whitewater boating flows downstream from McKay Station, as described above in table 1.

- Update the existing Recreation Plans for the Projects as part of the license applications.

**Cultural Resources**

- Develop updated Historic Properties Management Plans for the Projects.

## 3.2 DAM SAFETY

It is important to note that dam safety constraints may exist and should be taken into consideration in the development of proposals and alternatives considered in the pending proceedings. For example, proposed modifications to dam structures could impact the integrity of the dams' structures. As the proposals and alternatives are developed, the applicant must evaluate the effects and ensure that the Projects would meet the Commission's dam safety criteria found in Part 12 of the Commission's regulations and the Engineering Guidelines (http://www.ferc.gov/industries/hydropower/safety/guidelines/eng-guide.asp).

## 3.3 ALTERNATIVES TO THE PROPOSED ACTIONS

Commission staff will consider and assess all alternative recommendations for operational or facility modifications, as well as protection, mitigation, and enhancement measures identified by the Commission, the agencies, Native-American tribes, NGOs, and the public.

## 3.4 ALTERNATIVES CONSIDERED BUT ELIMINATED FROM DETAILED STUDY

At present, we propose to eliminate the following alternatives from detailed study in the NEPA document.

### 3.4.1 Federal Government Takeover

In accordance with § 16.14 of the Commission's regulations, a federal department or agency may file a recommendation that the United States exercise its right to take over

a hydroelectric power project with a license that is subject to sections 14 and 15 of the FPA.[21] We do not consider federal takeover to be a reasonable alternative. Federal takeover of the Projects would require congressional approval. While that fact alone would not preclude further consideration of this alternative, there is currently no evidence showing that federal takeover should be recommended to Congress. No party has suggested that federal takeover would be appropriate, and no federal agency has expressed interest in operating the Projects.

### 3.4.2 Non-power License

A non-power license is a temporary license the Commission would terminate whenever it determines that another governmental agency is authorized and willing to assume regulatory authority and supervision over the lands and facilities covered by the non-power license. At this time, no governmental agency has suggested a willingness or ability to take over the Projects. No party has sought a non-power license for either project, and we have no basis for concluding that the Ripogenus and Penobscot Mills Projects should no longer be used to produce power. Thus, we do not consider a non-power license a reasonable alternative to relicensing the projects.

### 3.4.3 Project Decommissioning

As the Commission has previously held, decommissioning is not a reasonable alternative to relicensing in most cases.[22] Decommissioning can be accomplished in different ways depending on the project, its environment, and the particular resource needs.[23] For these reasons, the Commission does not speculate about possible decommissioning measures at the time of relicensing, but rather waits until an applicant actually proposes to decommission a project, or a participant in a relicensing proceeding demonstrates that there are serious resource concerns that cannot be addressed with

[21] 16 U.S.C. §§ 791(a)-825(r).

[22] *See, e.g., Eagle Crest Energy Co*., 153 FERC ¶ 61,058, at P 67 (2015); *Public Utility District No. 1 of Pend Oreille County*, 112 FERC ¶ 61,055, at P 82 (2005); *Midwest Hydro, Inc*., 111 FERC ¶ 61,327, at PP 35-38 (2005).

[23] In the unlikely event that the Commission denies relicensing a project or a licensee decides to surrender an existing project, the Commission must approve a surrender "upon such conditions with respect to the disposition of such works as may be determined by the Commission." 18 C.F.R. § 6.2 (2020). This can include simply shutting down the power operations, removing all or parts of the project (including the dam), or restoring the site to its pre-project condition.

appropriate license measures and that make decommissioning a reasonable alternative.[24] GLHA does not propose decommissioning, nor does the record to date demonstrate there are serious resource concerns that cannot be mitigated if the projects are relicensed; as such, there is no reason, at this time, to include decommissioning as a reasonable alternative to be evaluated and studied as part of staff's NEPA analysis.

# 4.0 SITE-SPECIFIC RESOURCE ISSUES

## 4.1 RESOURCE ISSUES

In this section, we present a preliminary list of environmental issues to be addressed in the NEPA document. We identified these issues, which are listed by resource area, by reviewing the PAD and the Commission's record for the Ripogenus Project and Penobscot Mills Project. The environmental issues identified apply to both projects, unless otherwise specified in the issue description. This list is not intended to be exhaustive or final, but contains those issues raised to date that could have substantial effects. After the scoping process is complete, we will review the list and determine the appropriate level of analysis needed to address each issue in the NEPA document.

### 4.1.1 Geologic and Soils Resources

- Effects of continuing to operate the Projects on shoreline erosion in the impoundments.

- ***Effects of flow diversion and dewatering on sediment transport in the natural river channel's of the West Branch downstream from Ripogenus Dam and Stone Dam.***

### 4.1.2 Water and Aquatic Resources

- ***Effects of changes in historical project operation (based on generation records) on baseline flow patterns in the West Branch, and how such changes may affect aquatic resources in the vicinity of the Projects and***

[24] *See* generally *Project Decommissioning at Relicensing*; Policy Statement, FERC Stats. & Regs., Regulations Preambles (1991-1996), ¶ 31,011 (1994); *see also City of Tacoma, Washington,* 110 FERC ¶ 61,140 (2005) (finding that unless and until the Commission has a specific decommissioning proposal, any further environmental analysis of the effects of project decommissioning would be both premature and speculative).

***the West Branch, including the effect on fish migration timing and passage on the mainstem of the Penobscot River.***

- Effects of continuing to operate the Projects ***under the existing Water Use Plan and alternatives to that plan,*** on water quantity and flow in the West Branch ***and mainstem of the Penobscot River***, including effects on impoundment water levels***, the impoundments' ecosystems and biological communities, and downstream flow releases and*** flooding.

- Effects of continuing to operate the Projects***, including the flow release elevation at Ripogenus Dam,*** on DO concentrations and water temperature in the project impoundments and project-affected reaches downstream from project dams and powerhouses (e.g., Upper Gorge ***and the West Branch downstream from McKay Station;*** Holbrook Side Channel; ***the West Branch downstream from Stone Dam;*** Millinocket Stream***; and the mainstem Penobscot River***).

- Effects of drawdowns ***and fluctuating lake levels within*** the Ripogenus, North Twin, and Millinocket Lake impoundments on ***littoral habitat and associated aquatic communities, as well as*** access to impoundment tributaries for resident fish (e.g., landlocked salmon and rainbow smelt).

- ***Effects of operating the Ripogenus Project on lake whitefish populations in the Ripogenus impoundment.***

- ***Effects of operation of the Projects on aquatic insects, crayfish, and other macroinvertebates in the project impoundments and the West Branch (e.g., the Upper Gorge, Holbrook Side Channel, downstream from McKay Station, the West Branch downstream from Stone Dam, and Millinocket Stream).***

- Effects of continuing to operate the Projects on aquatic ***(littoral)*** habitat for resident ***and migratory*** fish and freshwater mussel species ***(as appropriate)*** in the project impoundments and project-affected reaches downstream from project dams and powerhouses (e.g., the Upper Gorge, Holbrook Side Channel, ***West Branch downstream from Stone Dam***, ***and*** Millinocket Stream).

- ***Effects of project flow diversion and dewatering of the river channel downstream from Ripogenus Dam and Stone Dam on fish populations and movement, aquatic habitat, and river connectivity.***

- ***Effects of the pumping operation at Millinocket Lake Storage Dam on flow releases into Millinocket Stream, including flow variability in relation to water quality maintenance, aquatic habitat, and recreation.***

- Effects of continuing to operate the Projects on upstream and downstream passage of American eels in the West Branch.

- Effects of continuing to operate the Projects on the movement of sea-run Atlantic salmon and alosines (American shad and river herring) in the West Branch and mainstem Penobscot River.

- ***Effects of potentially establishing invasive species in the Project impoundments and the West Branch from any fish passage for sea-run species.***

- Effects of continuing to operate the Projects on essential fish habitat for Atlantic salmon.

- Effects of continuing to operate the Projects on fish impingement, entrainment, and survival at the Projects' developments.

- ***Effects of continuing to operate the Projects on smelt abundance and downstream drift in the West Branch.***

- Effects of continuing to operate the Projects on state-protected aquatic species (e.g., brook floater, yellow lampmussel, and tidewater mucket).

### 4.1.3 Wildlife and Botanical Resources

- ***Effects of continuing to operate the Projects on wildlife resources within the project impoundments and the West Branch, including the effects of the drawdowns and low lake levels on riparian vegetation and associated wildlife around the Ripogenus Impoundment.***

- Effects of continuing to operate the Projects on wetlands, ***littoral*** and riparian habitat in, and along, the project impoundments, ***and the West Branch***.

- Effects of continuing to operate the Projects on state-protected wildlife and plant species (e.g., little brown bat, eastern small-footed bat, wood turtle, ***etc.***), ***including Species of Special Concern and Significant Wildlife Habitat listed under Maine's Natural Resources Protection Act and potentially in the project area***.

### 4.1.4 Threatened and Endangered Species

- Effects of continuing to operate and maintain the Projects on: (1) the federally threatened Canada lynx and its designated habitat and northern long-eared bat; and (2) the federally endangered Gulf of Maine Distinct Population Segment Atlantic salmon and its designated critical habitat***, including movement, restoration/recovery, and passage***.[25]

### 4.1.5 Recreation, Land Use, *and Aesthetics*

- Effects of continuing to operate and maintain the Projects on the project recreation facilities and their use, as well as ***(1) angling and*** recreational ***access/***opportunities on ***the project impoundments (including Caribou, Chesuncook, and Ripogenus Lakes) and*** the West Branch***; (2) public safety of recreational users of the lakes; (3) water supply to properties around Ripogenus Impoundment; and (4) educational opportunities***.

- Adequacy of existing project recreational facilities to meet existing and future recreational demand and capacity requirements.

- Adequacy of existing whitewater flows and access on the West Branch downstream from McKay Station***, the West Branch between Quakish Lake and Dolby Pond, and on Millinocket Stream***.

- ***Effects of continuing to operate and maintain the Projects, including the effects of the drawdowns and low lake levels, on aesthetic resources in the Projects' areas.***

[25] This list is derived from our July 28, 2021 search of the U.S. Fish and Wildlife Service's ECOS-IPaC website.

- ***Effects of continuing to operate the Projects on angling opportunities for landlocked Atlantic salmon and brook trout in the West Branch, including the river reach downstream from Ripogenus Dam.***

- ***Effects of flow releases in the Upper Gorge and whitewater releases from McKay Station on the brook trout fishery in the West Branch.***

### 4.1.6 Cultural Resources

- Effects of continuing to operate and maintain the Projects on ***historic and archaeological resources within the APE*** that are included in, or eligible for inclusion in, the National Register of Historic Places.

### *4.1.7 Socio-Economic Resources*

- ***Effects of the Projects' operation and maintenance on minority and low-income populations, including members of Native-American tribes.***

- ***Effects of the Projects' operation and maintenance on local, regional, and tribal economies.***

### 4.1.*8* Developmental Resources

- Effects of proposed or recommended environmental measures on the Projects' generation and economics.

## 5.0 PROPOSED STUDIES

GLHA's initial study proposals are identified by resource area for the Ripogenus Project (table 2) and the Penobscot Mills Project (table 3). Detailed information on GLHA's initial study proposals can be found in Section 6.2, *Proposed Studies and Information Gathering Associated with Identified Issues*, of the PAD. Further studies may need to be added to this list based on comments provided to the Commission and GLHA from ***agencies, Native-American Tribes, and interested stakeholders during the study planning process***.

**Table 2**. GLHA's initial study proposals for the Ripogenus Project. (Source: PAD).

| Resource area | Proposed Study |
|---|---|
| **Aquatic Resources** | |
| *Water Quality* | Collect water quality data in project impoundment, Upper Gorge, and downstream of McKay Station to inform FERC relicensing and the water quality certification process. |
| *Macroinvertebrate Community* | Conduct a survey to characterize the macroinvertebrate community downstream from McKay Station. |
| **Recreation, Land Use, and Aesthetics** | |
| *Recreation Facilities* | Characterize the existing recreation facilities in the project boundary, including their condition. |

**Table 3**. GLHA's initial study proposals for the Penobscot Mills Project. (Source: PAD).

| Resource area | Proposed Study |
|---|---|
| **Aquatic Resources** | |
| *Water Quality* | Collect water quality data in the impoundments and riverine/tailwater areas of each development to inform FERC relicensing and the water quality certification process. |
| *Macroinvertebrate Community* | Conduct a survey to characterize the macroinvertebrate community in each of the tailwater and riverine reaches. |
| *Aquatic Habitat* | Map and characterize aquatic and riparian mesohabitat types in the ***West Branch downstream from Stone Dam (***Millinocket Development***)*** under the existing flow regime. |
| **Recreation, Land Use, and Aesthetics** | |

| Resource area | Proposed Study |
|---|---|
| *Recreation Facilities* | Characterize the existing recreation facilities in the project boundary, including their condition. |

## 6.0 EA PREPARATION SCHEDULE

The decision on whether to prepare an EA or EIS will be determined after the license application is filed and we fully understand the scope of effects and measures under consideration. ***Nonetheless, at this time, we anticipate the need to prepare a draft and final NEPA document. The draft NEPA document will be sent to all persons and entities on the Commission's service and mailing lists for the Projects.*** The NEPA document will include our recommendations for operating procedures, as well as PM&E measures that should be part of any license issued by the Commission. ***All recipients will then have 30 to 45 days to review the EA, or 60 days to review the EIS, and file written comments with the Commission. All comments on the draft NEPA document filed with the Commission will be considered in preparation of the final NEPA document.***

***The major milestones, including those for preparing the NEPA document, are as follows:***

| ***Major Milestone*** | ***Target Date*** |
|---|---|
| ***License Application Filed*** | ***September 30, 2024*** |
| ***Ready for Environmental Analysis Notice Issued*** | ***November 29, 2024*** |
| ***Deadline for Filing Comments, Recommendations, and Agency Terms and Conditions/Prescriptions*** | ***January 28, 2025*** |
| ***Drat NEPA Document Issued*** | ***August 15, 2025*** |
| ***Comments on Draft NEPA Document Due*** | ***September 14, 2025*** |
| ***Deadline for Filing Modified Agency Recommendations*** | ***November 13, 2025*** |
| ***Final NEPA Document Issued*** | ***February 3, 2026*** |

***If Commission staff determines that there is a need for additional information or additional studies, the issuance of the Ready for Environmental Analysis notice could be delayed. If this occurs, all subsequent milestones would be delayed by the time allowed for the licensee to respond to the Commission staff's request.***

A copy of GLHA's process plan for developing the license application is attached as Appendix ***A*** to this ***SD2***.

## *7.0 PROPOSED NEPA DOCUMENT OUTLINE*

***The preliminary outline for the Ripogenus and Penobscot Mills Projects' NEPA document is as follows:***

***TABLE OF CONTENTS***
***LIST OF APPENDICES***
***LIST OF FIGURES***
***LIST OF TABLES***
***ACRONYMS AND ABBREVIATIONS***

1. ***INTRODUCTION***
    - ***1.1 Application***
    - ***1.2 Purpose of Action and Need for Power***
    - ***1.3 Statutory and Regulatory Requirements***
        - ***1.3.1 Federal Power Act***
            - ***1.3.1.1 Section 18 Fishway Prescriptions***
            - ***1.3.1.2 Section 10(j) Recommendations***
        - ***1.3.2 Clean Water Act***
        - ***1.3.3 Endangered Species Act***
        - ***1.3.4 National Historic Preservation Act***
    - ***1.4 Public Review and Comment***
        - ***1.4.1 Scoping***
        - ***1.4.2 Interventions***
        - ***1.4.3 Comments on the Application***
        - ***1.4.4 Comments on the Draft Environmental Document***
2. ***PROPOSED ACTION AND ALTERNATIVES***
    - ***2.1 No-action Alternative***
    - ***2.2 Applicant's Proposal***
        - ***2.2.1 Ripogenus Project***
        - ***2.2.2 Penobscot Mills Project***
    - ***2.3 Staff Alternative***
        - ***2.3.1 Ripogenus Project***
        - ***2.3.2 Penobscot Mills Project***
    - ***2.4 Staff Alternative with Mandatory Conditions***
    - ***2.5 Other Alternatives (as appropriate)***
    - ***2.6 Alternatives Considered but Eliminated from Detailed Study***
        - ***2.6.1 Federal Government Takeover of the Projects***
        - ***2.6.2 Issuing a Nonpower License***

*2.6.3 Retiring the Projects*
*3. ENVIRONMENTAL ANALYSIS*
*3.1 General Description of the River Basin*
*3.2 Proposed Action and Action Alternatives*
*3.2.1 Geology and Soils*
*3.2.2 Water Resources*
*3.2.3 Fish and Aquatic Resources*
*3.2.4 Terrestrial Resources*
*3.2.5 Threatened and Endangered Species*
*3.2.6 Recreation, Land Use, and Aesthetics*
*3.2.7 Cultural Resources*
*3.2.8 Socioeconomics*
*3.3 No-action Alternative*
*4. DEVELOPMENTAL ANALYSIS*
*4.1 Power and Economic Benefits of the Projects*
*4.2 Comparison of Alternatives*
*4.3 Cost of environmental Measures*
*5. CONCLUSIONS AND RECOMMENDATIONS*
*5.1 Comprehensive Development and Recommended Alternative*
*5.2 Unavoidable Adverse Effects*
*5.3 Recommendations of Fish and Wildlife Agencies*
*5.4 Consistency with Comprehensive Plans*
*6. FINDING OF NO SIGNIFICANT IMPACT [OR SIGNIFICANT IMPACT]*
*7. LITERATURE CITED*
*8. LIST OF PREPARERS*

*APPENDICES*
*A – Draft License Conditions Recommended by Staff*

## 8.0 COMPREHENSIVE PLANS

Section 10(a)(2) of the FPA, 16 U.S.C. Section 803(a)(2)(A), requires the Commission to consider the extent to which a project is consistent with federal and state comprehensive plans for improving, developing, or conserving a waterway or waterways affected by a project. The staff has preliminarily identified and reviewed the plans listed below that may be relevant to the Projects. Agencies are requested to review this list and inform the Commission staff of any changes. If there are other comprehensive plans that should be considered for this list that are not on file with the Commission, or if there are more recent versions of the plans already listed, they can be filed for consideration with the Commission according to 18 CFR 2.19 of the Commission's regulations. Please

follow the instructions for filing a plan at http://www.ferc.gov/industries/hydropower/gen-info/licensing/complan.pdf.

The following is a list of comprehensive plans currently on file with the Commission that may be relevant to the Projects:

Atlantic States Marine Fisheries Commission. 1999. Amendment 1 to the Interstate Fishery Management Plan for shad and river herring. (Report No. 35). April 1999.

Atlantic States Marine Fisheries Commission. 2000. Interstate Fishery Management Plan for American eel (*Anguilla rostrata*). (Report No. 36). April 2000.

Atlantic States Marine Fisheries Commission. 2000. Technical Addendum 1 to Amendment 1 of the Interstate Fishery Management Plan for shad and river herring. February 9, 2000.

Atlantic States Marine Fisheries Commission. 2008. Amendment 2 to the Interstate Fishery Management Plan for American eel. Arlington, Virginia. October 2008.

Atlantic States Marine Fisheries Commission. 2009. Amendment 2 to the Interstate Fishery Management Plan for shad and river herring. Arlington, Virginia. May 2009.

Atlantic States Marine Fisheries Commission. 2010. Amendment 3 to the Interstate Fishery Management Plan for shad and river herring, Arlington, Virginia. February 2010.

Atlantic States Marine Fisheries Commission. 2013. Amendment 3 to the Interstate Fishery Management Plan for American eel. Arlington, Virginia. August 2013.

Atlantic States Marine Fisheries Commission. 2014. Amendment 4 to the Interstate Fishery Management Plan for American eel. Arlington, Virginia. October 2014.

Maine Atlantic Sea-Run Salmon Commission. 1984. Strategic plan for management of Atlantic salmon in the State of Maine. Augusta, Maine. July 1984.

Maine Department of Agriculture, Conservation, & Forestry. Maine State Comprehensive Outdoor Recreation Plan (SCORP): 2014-2019. Augusta, Maine.

Maine Department of Conservation. 1982. Maine Rivers Study-final report. Augusta, Maine. May 1982.

Maine Department of Marine Resources. Maine Department of Inland Fisheries and Wildlife. 2008. Strategic Plan for the Restoration of Diadromous Fishes to the Penobscot River. Augusta, Maine. March 2008

Maine Department of Marine Resources. Maine Department of Inland Fisheries and Wildlife. 2008. Operational Plan for the Restoration of Diadromous Fishes to the Penobscot River. Augusta, Maine. July 2, 2009.

Maine State Planning Office. 1987. Maine Comprehensive Rivers Management Plan Vols 1-3. Augusta, Maine. May 1987.

Maine State Planning Office. 1992. Maine Comprehensive Rivers Management Plan. Volume 4. Augusta, Maine. December 1992.

National Marine Fisheries Service. 1998. Final Amendment #11 to the Northeast Multi-species Fishery Management Plan; Amendment #9 to the Atlantic sea scallop fishery Management Plan; Amendment #1 to the Atlantic salmon Fishery Management Plan; and Components of the Proposed Atlantic herring Fishery Management Plan for Essential Fish Habitat. Volume 1. October 7, 1998.

National Marine Fisheries Service. 2018. Recovery Plan for the Gulf of Maine Distinct Population Segment of Atlantic Salmon. Hadley, Massachusetts. January 2019.

National Park Service. 1993. The Nationwide Rivers Inventory. Department of the Interior, Washington, D.C.

U.S. Fish and Wildlife Service. 1989. Atlantic salmon restoration in New England: Final environmental impact statement 1989-2021. Department of the Interior, Newton Corner, Massachusetts. May 1989.

U.S. Fish and Wildlife Service. n.d. Fisheries USA: the recreational fisheries policy of the U.S. Fish and Wildlife Service. Washington, D.C.

U.S. Fish and Wildlife Service. Canadian Wildlife Service. 1986. North American waterfowl management plan. Department of the Interior. Environment Canada. May 1986.

## 9.0 MAILING LISTS

The lists below are the Commission's official mailing lists for the Projects. If you want to receive future mailings for these proceedings and are not included in the lists below, please send your request by email to efiling@ferc.gov, or by mail to: Kimberly D. Bose, Secretary, Federal Energy Regulatory Commission, 888 First Street, N.E., Room 1A, Washington, DC 20426. Submissions sent via any other carrier must be addressed to: Kimberly D. Bose, Secretary, Federal Energy Regulatory Commission, 12225 Wilkins Avenue, Rockville, Maryland 20852. All written and emailed requests to be added to the mailing lists must clearly identify the following on the first page, as appropriate: **Ripogenus Hydroelectric Project (P-2572-133)** and/or **Penobscot Mills Hydroelectric Project (P-2458-247).** You may use the same method if requesting removal from the mailing lists below.

Register online at http://www.ferc.gov/docs-filing/esubscription.asp to be notified via email of new filings and issuances related to these Projects or other pending projects. For assistance, please contact FERC Online Support at Mailto:FERCOnlineSupport@ferc.gov, or toll free at 1-866-208-3676, or for TTY, (202) 502-8659.

**Subject:** **Ripogenus Hydroelectric Project (FERC No. 2572-133)**
**Penobscot Mills Hydroelectric Project (FERC No. 2458-247)**
**Proposed Study Plan**

Dear Secretary Bose:

Great Lakes Hydro America, LLC (GLHA), a subsidiary of Brookfield Renewable and Licensee of the Ripogenus Hydroelectric Project (FERC No. 2572) and Penobscot Mills Hydroelectric Project (FERC No. 2458) (collectively referred to as the "Projects"), herein files with the Federal Energy Regulatory Commission (FERC or Commission) the Proposed Study Plan (PSP) for the relicensing of the Projects. The Projects are located on the West Branch of the Penobscot River and Millinocket Stream in Piscataquis and Penobscot Counties, Maine.

On June 11, 2021, GLHA filed the Notices of Intent and Pre-Application Document (PAD), which initiated the formal relicensing proceeding to obtain two separate new licenses for the continued operation of the Projects through the Commission's Integrated Licensing Process (ILP). Subsequently, FERC issued Scoping Document 1 (SD1) on August 10, 2021 and held daytime and evening virtual scoping meetings on September 9, 2021.[1] Additionally, on the afternoon of September 9, 2021, GLHA hosted a virtual environmental site review.

Approximately 50 stakeholders filed letters with FERC providing general comments, comments regarding the PAD, comments regarding SD1, and/or study requests. Based on the stakeholder requested studies, GLHA is proposing the following studies:

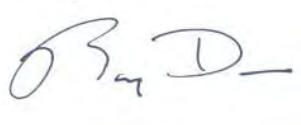
1. Water Quality Study consisting of the following:
    a. Impoundment Trophic State Study (Ripogenus & Penobscot Mills Projects)
    b. Impoundment Aquatic Habitat Assessment (Ripogenus & Penobscot Mills Projects)
    c. Downstream Temperature and Dissolved Oxygen Study (Ripogenus & Penobscot Mills Projects)
    d. Riverine Aquatic Habitat Assessment (Ripogenus & Penobscot Mills Projects)
    e. Benthic Macroinvertebrate Assessment (Ripogenus & Penobscot Mills Projects)
2. Back Channel Instream Flow and Habitat Assessment Study (Penobscot Mills Project)

[1] As specified in SD1, the Commission did not conduct in-person public scoping meetings or in-person environmental site reviews due to concerns with COVID-19.

Great Lakes Hydro America, LLC
1024 Central Street
Millinocket, ME 04462
www.brookfieldrenewable.com
Tel: 207.723.4341
Fax: 207.723.3948

3. North Twin Impoundment Tributary Access Survey (Penobscot Mills Project)
4. Upstream Eel Passage Assessment Study (Penobscot Mills Project)
5. Desktop Downstream Eel Passage Assessment Study (Ripogenus & Penobscot Mills Projects)
6. Recreation Study (Ripogenus and Penobscot Mills Projects)
7. Historic Architectural Survey (Ripogenus & Penobscot Mills Projects)
8. Historic Operations Data and Assessment Study (Ripogenus & Penobscot Mills Projects)

As described in Section 4.0 of the PSP, GLHA intends to hold a virtual Proposed Study Plan Meeting on December 15-16, 2021 from 9:00 AM to 4:30 PM. **Stakeholders interested in participating in the PSP Meeting via webinar must RSVP to Cate Russell of HDR at cate.russell@hdrinc.com by December 10, 2021**. Prior to the meeting, GLHA will provide interested parties with a meeting invitation via email with the necessary webinar link.



Pursuant to the schedule provided by FERC in SD1, comments on the PSP are due to FERC by February 21, 2022.

In comment letters received, stakeholders requested additional information be provided in the PSP. Where available, GLHA has compiled this information and included it in the PSP. However, additional information to address select requests require further research and will be provided in a supplemental filing (e.g., Revised Study Plan).

Concurrent with this filing, GLHA is providing a copy of this letter to all parties listed in the attached distribution list. Parties with interest in the upcoming relicensing can download an electronic copy of the PSP from FERC's eLibrary system at https://www.ferc.gov/docs-filing/elibrary.asp by conducting a search using the docket numbers p-2458 and/or p-2572.

If you have any questions regarding the PSP, please contact me by phone at (207) 775-5605 or by email at randy.dorman@brookfieldrenewable.com.

Sincerely,

Randall Dorman
Licensing Manager
Brookfield Renewable

VIA Electronic Filing

**Reference: Scoping Document 2 for the Ripogenus Hydroelectric Project (P-2572-133) and Penobscot Mills Hydroelectric Project (P-2458-247)**

**RE; Scoping Document 2; Deficiencies: Lack of Hourly Flow, Lake Elevation and Power Generation for the Above Referenced Projects**

**For 25 plus years I worked for Great Northern Paper (GNP) and its successors. My field of responsibilities was the West Branch drainage from the Canadian border to the East Millinocket facility. My primary responsibility was collection and analysis of fisheries data and I co-authored the Ripogenus and Penobscot Mills Projects FERC License Application. Along with GNP's staff, I collected the fisheries information presented in the Licensee's various relicensing filings. As Project operations have changed, these 1980's data are no longer valid. I find the reliance on 35 year-old (pre peaking) data and the lack of quantifiable current fisheries and flow and elevation data very disturbing. The Licensee mentions "access to source material" in regard to current, useful information, this action has been impossible.**

**During all phases of this relicensing there have been numerous agency and stakeholder requests, directly or inferentially, for flow, lake elevation, and energy output from the facilities under consideration for a 30-year FERC license. While, by inference, FERC appears ready to consider these parameters, no current hourly tabular data have been presented in any filings. In formulating study and additional information requests, there are significant difficulties in judging impacts on fish, aquatic communities, recreation (boating and fishing) and aesthetics without hourly data for river flows, lake elevations and energy**

**production. These data should include at least 10 consecutive years ending in November 2021.**

**Presently Brookfield provides real-time McKay Station flow information (to the public) on a website called Safe Waters. There is no real-time flow for the five downriver facilities (North Twin, Millinocket, Dolby, East Millinocket, Medway) or archival information for any of the six generating facilities. Thus, there is no information on which to evaluate existing fishing opportunity, salmon and trout habitat, and littoral zone areas (smelt and plankton production). This makes identifying "data gaps" and commenting on proposed studies exceedingly difficult, if not impossible. This lack of project information is NOT what Scoping Document 1 suggests when it asks for input and comments.**

**Does FERC already to have the needed flow, lake level and perhaps energy production data? If so, FERC should make it widely available. These flow and elevation data are required as a monitoring condition in the WQC, Article 403 (2) and echoed similarly in the Appendix (Minimum Flows). These conditions are shown below, emphasis has been added;**

ARTICLE 403 (2)
"….the locations and ***methods to be used for recording data on minimum flows, and the plan for maintaining accurate records of these data*** **for inspection** and filing with the commission and resource agencies." (emphasis added)

APPENDIX Minimum Flows
"***The applicant shall continue to keep accurate flow records*** and monitor recreational use; shall review the effectiveness of its Water Use Plan with the commission,….". (emphasis added)

These data must exist and clearly FERC has easy access to the needed material. Average daily, weekly or monthly data either graphically or in summary form, are useless from a fisheries or aquatic communities prospective. For example, the licensee's September 30, 2021 submittal of the 1996 EIS lists figures D 7-9 of the Appendix are based on "averages". These figures (as well as summary tables) do not reflect instantaneous flow conditions e.g., peaks or valleys during critical feeding periods, predator avoidance, vertical or lateral salmonid movement, spawning activity, smelt drift, aquatic insect emergence/"hatches". These data are critical in evaluating angler use and success and the health of the fish and aquatic communities. Hourly tabular flow, elevation and energy production data has been

requested by the agencies and stakeholders and are desperately needed to make the licensing “process” work.

In the event FERC doesn’t have readily available access to the requested data, the licensee operates the reference projects remotely and through a computerized system. Archival data was used by the licensee to produce flow summary tables and figures used in the NOI and PAD. Thus, providing the needed hourly (average) flow, lake elevation and energy generation data will only require a phone call and a few “key strokes”.

Please make public flow, lake elevation and energy production data of the above referenced facilities available to the agencies and stakeholders in the requested hourly, tabular form.

VIA Electronic Filing

**Reference: Ripogenus Project Hydroelectric Project(P-2572-133) and Penobscot Mills Hydroelectric Project (P-2458-247) The Licensee's Filing of November 22, 2021, Proposed Study Plan, Upstream Eel Passage Assessment**

**RE: Critical Missing Data, 1990's Millinocket Stream Eel Fishery.**

**The Licensee continues to claim that existing fisheries and aquatic communities information is adequate for FERC to issue new licenses for the above referenced projects. This is clearly not the case at Millinocket Stream, the outlet of Millinocket Lake, a storage impoundment of the Penobscot Mills Project (P-2458). In the case of Millinocket Stream, the license was either unaware or withheld "archival file information" on an eel fishery discussed below. This information could aid agencies, NGOs and FERC evaluate the Licensee's November 22, 2021 Eel Passage Assessments Study response to their (eel) study requests.**

**As required by WQC's Article 413, (brook trout stocking) GNP monitored Millinocket Stream angler use and success that resulted from annual stockings. These studies began in the late 1990s. I and other GNP staff members surveyed anglers three or four days a week from May though September. For several years there was an eel weir located just downstream of Stacyville Road Bridge. This bridge/weir location was a common "fishing site" as well as providing parking for anglers whom choose to move downriver. Anglers fishing this site were often recorded (on GNP creel survey forms) as (fishing at the) "bridge" or "eel weir". This parking area was also a place where the eel weir operator parked. The weir was operated by Rodney Corriveau (presently living in Millinocket, Maine) during parts of August, September and October (depending on flow). From conversation with the weir operator, eel outmigration occurred during certain moon phases and in conjunction with fall freshets resulting in high discharges from Millinocket Lake Dam. From conversations with Mr. Corriveau, annual catches reached two to three thousand pounds of eel. The licensee failed to include information on the 1990's intercept (weir) fishery of out-migrating (adult) eel in any of its voluminous filings e.g., The Licensee's PAD p 5-96. Section 3.2 of the Licensee's Proposed Study Plan states eel are present in "limited numbers". For the Millinocket Lake Impoundment and the downstream weir fishery, is not the case. Eel studies have been requested in four differing (upstream, downstream passage, etc.) agency filings. The licensee's failure to reference this fishery and provide "archival file" data or common public knowledge is disturbing. The history of this eel weir fishery needs to be provided to interested parties.**

Document Accession #: 20211206-5088 Filed Date: 12/06/2021

December 6, 2021

VIA Electronic Filing

**Reference: Scoping Document 2 for the Ripogenus Hydroelectric Project (P-2572-133) and Penobscot Mills Hydroelectric Project (P-2458-247)**

**RE: Scoping Document 2; Deficiencies: Lack of Plan(S) to Identify Fish Populations and Angler Use in the Above Referenced Projects.**

**Throughout the scoping process including the licensee's responses, there been requests and rebuttals regarding the current status of fish (salmonid) and angler use and success at the above referenced projects. The licensee continues to make the unsubstantiated claim that the existing suite of pre-peaking archival (1980s) angler use and success and salmonid growth and condition information is an adequate base for insurance of a 30-year license. Scoping Document one and two have been strangely silent in their response and the "path forward" is unknown in regard to collection of angler and fisheries data.**

**Scoping Document II appears recognize that fish, salmon and trout, and angler use and success is a component of the NEPA process. FERC writes in section 2.3 titled *Issues Raised During Scoping***

"The marjority of comments identified concerns about project operations and potential project effects on water quality, didamdromous fish passsage, ***fish and wildlife resources and habitat, recreational oportunities*** ….." emhasis added

**However, FERC has failed to indicate how fisheries and aquatic communities data critical to NEPA process will be collected. The reader is left with the impression that FERC may accept the licensee's ridiculous assertion that 35-year pre-peaking fisheries and aquatic communities data for the Ripogenus Project and 30 year old pre-peaking fisheries and aquatic communities data for Penobscot Mills Project provide a sound base on which to issue a 30-year license(s). These data are desperately needed for riverine reaches. The** agencies and stakeholders need to know exactly how and when critical fisheries information including angler use data will be collected and FERC needs to clarify their intentions. If FERC is not intending to require the many times request fisheries (including angler surveys) and aquatic data, FERC has an obligation to state that and the reasons for refusal.

December 8, 2021

*Via Electronic Filing*

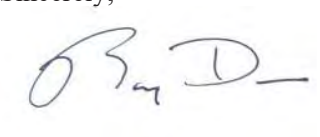
Kimberly D. Bose, Secretary
Federal Energy Regulatory Commission
888 First Street, NE
Washington, DC 20426

**Subject:** **Ripogenus Hydroelectric Project (FERC No. 2572-133)**
**Penobscot Mills Hydroelectric Project (FERC No. 2458-247)**
**Proposed Study Plan Meeting Agenda**

Dear Secretary Bose:

Great Lakes Hydro America, LLC (GLHA), a subsidiary of Brookfield Renewable and Licensee of the Ripogenus Hydroelectric Project (FERC No. 2572) and Penobscot Mills Hydroelectric Project (FERC No. 2458) (collectively referred to as the "Projects"), herein files with the Federal Energy Regulatory Commission (FERC or Commission) the detailed agenda for the upcoming Proposed Study Plan Meeting scheduled to occur on December 15 and 16, 2021 for the Projects. The Projects are located on the West Branch of the Penobscot River and Millinocket Stream in Piscataquis and Penobscot Counties, Maine.

On June 11, 2021, GLHA filed the Notices of Intent and Pre-Application Document, which initiated the formal relicensing proceeding to obtain two separate new licenses for the continued operation of the Projects through the Commission's Integrated Licensing Process (ILP). Subsequently, FERC held daytime and evening virtual scoping meetings on September 9, 2021. Additionally, on the afternoon of September 9, 2021, GLHA hosted a virtual environmental site review.



Pursuant to the ILP, on November 23, 2021, GLHA filed a Proposed Study Plan (PSP) with FERC. As described in Section 4.0 of the PSP, GLHA will hold a virtual PSP Meeting on December 15-16, 2021 from 9:00 AM to 4:30 PM, which will follow the enclosed agenda.

**Stakeholders interested in participating in the PSP Meeting via webinar must RSVP to Cate Russell of HDR at cate.russell@hdrinc.com by December 10, 2021**. Prior to the meeting, GLHA will provide interested parties with a meeting invitation via email with the necessary webinar link.

Concurrent with this filing, GLHA is providing a copy of this letter to all parties listed in the attached distribution list. Parties with interest in the relicensing can download an electronic copy of the PSP from FERC's eLibrary system at https://www.ferc.gov/docs-filing/elibrary.asp by conducting a search using the docket numbers p-2458 and/or p-2572.

If you have any questions regarding the enclosed PSP Meeting agenda, please contact me by phone at (207) 775-5605 or by email at randy.dorman@brookfieldrenewable.com.

Sincerely,

Randall Dorman
Licensing Manager
Brookfield Renewable

**Penobscot Mills Hydroelectric Project (FERC No. 2458)**
**Proposed Study Plan Meeting Agenda**
**December 15 & 16, 2021**

****This is a running agenda, therefore times are estimated.****

| Estimated Time** | Topic |
|---|---|
| **December 15** | |
| 9:00-9:15 | Welcome, Housekeeping, Introductions, Relicensing Schedule |
| 9:15-9:30 | Project Overview |
| 9:30-9:45 | Additional Information Requests |
| 9:45-9:50 | FERC Study Criteria |
| 9:50-10:00 | Overview of Study Requests |
| 10:00-10:15 | Proposed Historic Operations Data and Assessment Study |
| 10:15-10:30 | Proposed Historical Architectural Survey |
| 10:30-11:30 | Proposed Recreation Study |
| 11:30-12:00 | Requested Controlled Flow Whitewater Boating and Access Study |
| 12:00-12:15 | Requested Aesthetic Resources Study |
| 12:15-12:30 | Requested Socioeconomics Study |
| 12:30-1:00 | 30-minute lunch break |
| 1:00-3:30 | Proposed Water Quality Study |
| **December 16** | |
| 9:00-9:15 | Welcome, Housekeeping, Introductions, Relicensing Schedule |
| 9:15-9:30 | Project Overview |
| 9:30-9:45 | Additional Information Requests |
| 9:45-9:50 | FERC Study Criteria |
| 9:50-10:00 | Overview of Study Requests |
| 10:00-10:30 | Proposed Back Channel Instream Flow and Habitat Assessment Study |
| 10:30-11:00 | Proposed North Twin Impoundment Tributary Access Survey |
| 11:00-11:30 | Proposed Upstream Eel Passage Assessment Study |
| 11:30-12:00 | Proposed Desktop Downstream Eel Passage Assessment Study |
| 12:00-12:15 | Requested 3D Computational Fluid Dynamics Modeling Upstream and Downstream of the Discharge and in Vicinity of Powerhouse Forebays |
| 12:15-12:30 | Requested Evaluation of American Eel Size and Timing of Downstream Migratory Movements |
| 12:30-1:00 | 30-minute lunch break |
| 1:00-1:15 | Requested Downstream American Eel Passage Alternatives Study |
| 1:15-1:30 | Requested Upstream Fish Passage Alternatives Study |
| | Requested Downstream Fish Passage Alternatives Study |
| 1:30-1:45 | Requested Study to Evaluate the Effects of Operating the Penobscot Mills and Ripogenus Dams on the Hydrology of the West Branch and Mainstem Penobscot River Using an Indicators of Hydrologic Alteration Model |
| | Requested Study to Evaluate Project Effects on River Temperature in West Branch and Mainstem Penobscot River |
| | Requested Study to Evaluate Future Flow and Water Temperature Scenarios |
| 1:45-2:00 | Requested Fish Assemblage Study |
| 2:00-2:15 | Requested Freshwater Mussel Survey |
| 2:15-2:30 | Requested Ripogenus Flow Excursion Study |
| 2:30-2:45 | Requested Terrestrial, Wildlife, and Botanical Resources Study |
| 2:45-3:00 | Requested Northern Long-eared Bat Acoustic Survey |
| 3:00-3:15 | Requested Study to Assess Presence of Wood Turtles and Project Effects on Nesting Habitat, Nesting Success, and Overwintering Habitat |
| 3:15-3:30 | Requested Marsh Bird Surveys |
| 3:30-3:45 | Requested Furbearer Surveys |
| 3:45-4:00 | Requested Common Loon Productivity Assessment |
| 4:00-4:15 | Requested Common Loon Management Plan Assessment |
| 4:15-4:30 | Next Steps |

There has been much discussion on collecting new data to assess the existing water Management plan and the impacts it has had on water quality, the environment, and the recreational use of natural resources. However, there has been little discussion of the need to monitor the future impacts of climate change on the critical assumptions that would be used to to develop a new water management plan and or manage the water resources during a new license period which could be as long as 50 years.
One of the most critical assumptions of the water Management plan is the estimated inflows to the impoundment. The water inflows to the impoundment are a direct consequence of the climactic conditions such as snowfall, time duration of the snow melt, and obviously rainfall. Yet, it is these very conditions that the global scientific community has recognized will be significantly affected by climate change.
The Commission has expressed its concern about using climate change models or assessment that would support, with any degree of accuracy and reliability, prediction of water availability at the individual project level.
The very fact that the Commission does not feel that there is adequate climate research and modeling that applies to this specific project area speaks to the need of having a dynamic water Management plan that continually monitors and assesses any future changes to the critical assumptions of the water Management plan and modifies those assumptions if the new data indicates the old assumptions are no longer relevant.
These future measurements should include:
- daily impoundment elevations
- daily outflows ( minimum, maximum, and average discharges)
This type of information was requested by FERC for a 10-year historical period. It is this type of information that needs to be monitored during the entire new license period for the reason stated above.

Additionally, the Ripogenus impoundment is comprised of multiple basins, each with their own characteristics. A study should be taken to determine the percent increase of littoral habitat exposure for each of the Ripogenus basins at various water elevations. It is clear from intervener comments that Caribou lake has been severely harmed by drastic increases in the acreage of the littoral habitat exposure, and I believe disproportionately as compared to the other lakes in the impoundment. This data could be used to develop a drawdown restriction as has been established in other Maine impoundments.
It is essential for all these reasons that the commission establish a dynamic water Management plan that allows for it to be adjusted to reflect changing climactic conditions. It would be reckless to do otherwise.

David Ahola, Veazie, ME.
I been fishing the West Branch of the Penobscot River for the past 20 years. The quality of fishing has continually declined over the past several years. There are few salmon in the reaches below the Big Eddy, and those there are both smaller and less healthy (skinny). Water levels rise in the morning and fall in the evening, making angling difficult. This has gotten to the point that I rarely make trips back up to one of my favorite fishing spots. FERC needs to correct the recent change in project operations back to historical constant base flow. Thank you for giving proper attention to this important matter. This is having a detrimental effect on the West Branch fishery and the local economy.
David Ahola, M.D.

**Via online submission to: http://www/ferc.gov (cross-filed)**

Subject: **Maine Council of Trout Unlimited Amplifying Report for Observed Low Flow Events for the Ripogenus Project (P-2572)**

Dear Secretary Bose:

On behalf of its six chapters and over 2,000 members, Maine Council of Trout Unlimited (TU) submits this report in amplification of the report of low flow events for the Ripogenus Project (P-2572) that TU filed on September 21, 2021.

**Background**

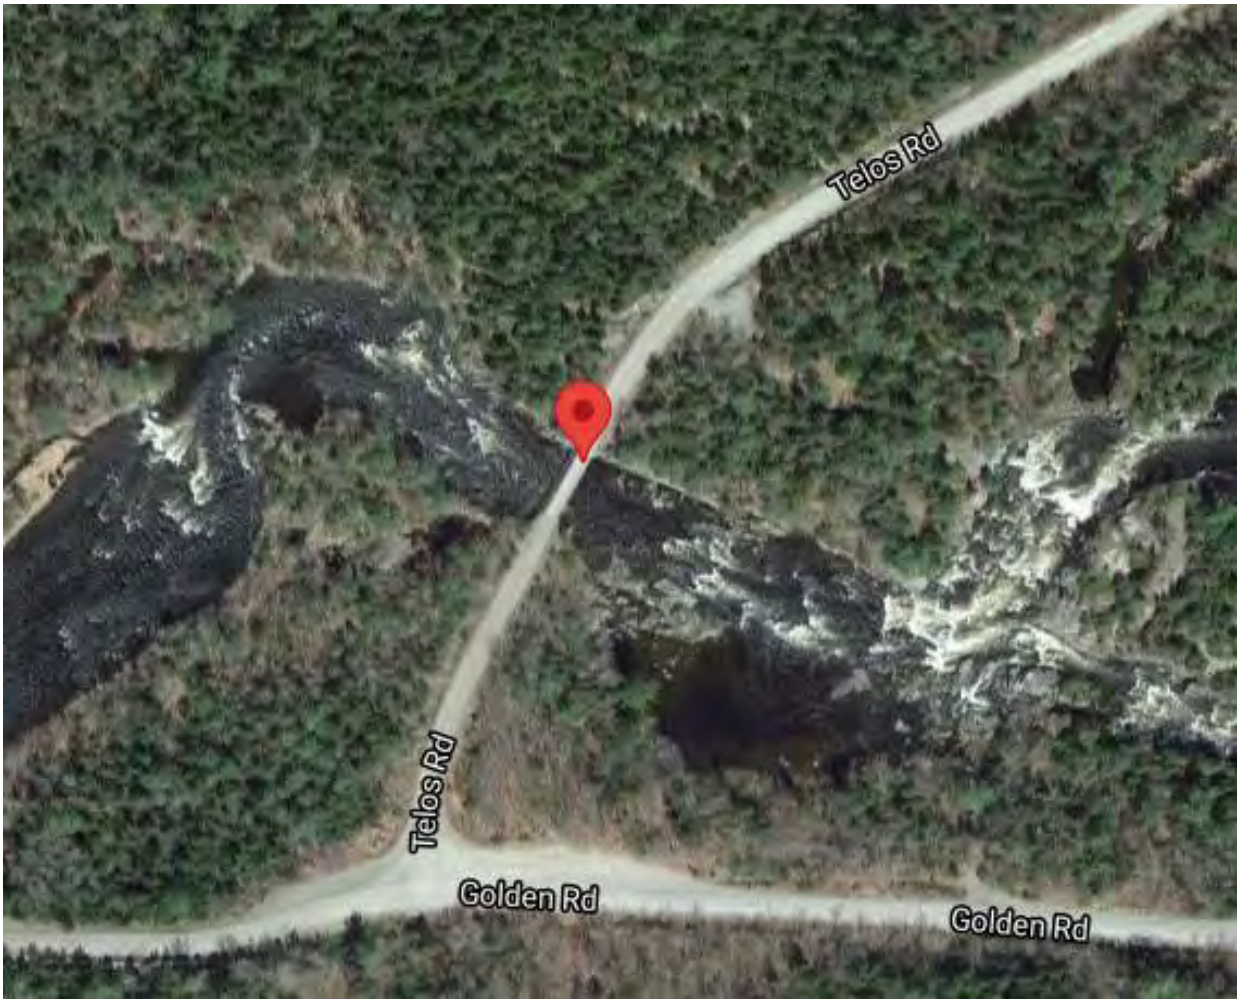
On August 30, 2021, an apparent flow excursion was witnessed below Ripogenus Dam by Chewonki Campground staff who informed TU of the event and provided photos. Such events have been occurring for the last ten years or more, but seem to be on the increase of late. The operator has generally reported them within ten days of their occurrence and we expected that to be case in this instance, but that did not occur. On September 13, TU called the FERC hotline and spoke with FERC official Mark Carter who explained that he would pass the information to appropriate FERC staff and that someone would be in contact with us. Hearing nothing back, we called again on September 15, and received the same assurance. On September 16, we were contacted by FERC official Alicia Burtner.[1] She explained how to report the event using FERC Online. Later that day, Chewonki Campground staff reported witnessing another low flow event. Rather than file a report of a separate event TU filed the report of the September 16 event with our report of the August 30 event.

To complicate matters, subsequent to the drafting of that report, Brookfield reported an excursion event that occurred on September 10, 2021.[2] It does not correlate with either of the flow events contained in our September 21, 2021 report. The Commission subsequently ruled that the September 10 flow event did constitute a license violation.[3]

Miles Puleio, who fishes and kayaks on the West Branch of the Penobscot River, participated in the proposed Study Plan Teleconference for the Ripogenus and Penobscot Mills project relicensings held on December 16, 2021.[4] Topics discussed included the study plan request submitted by TU for a Ripogenus

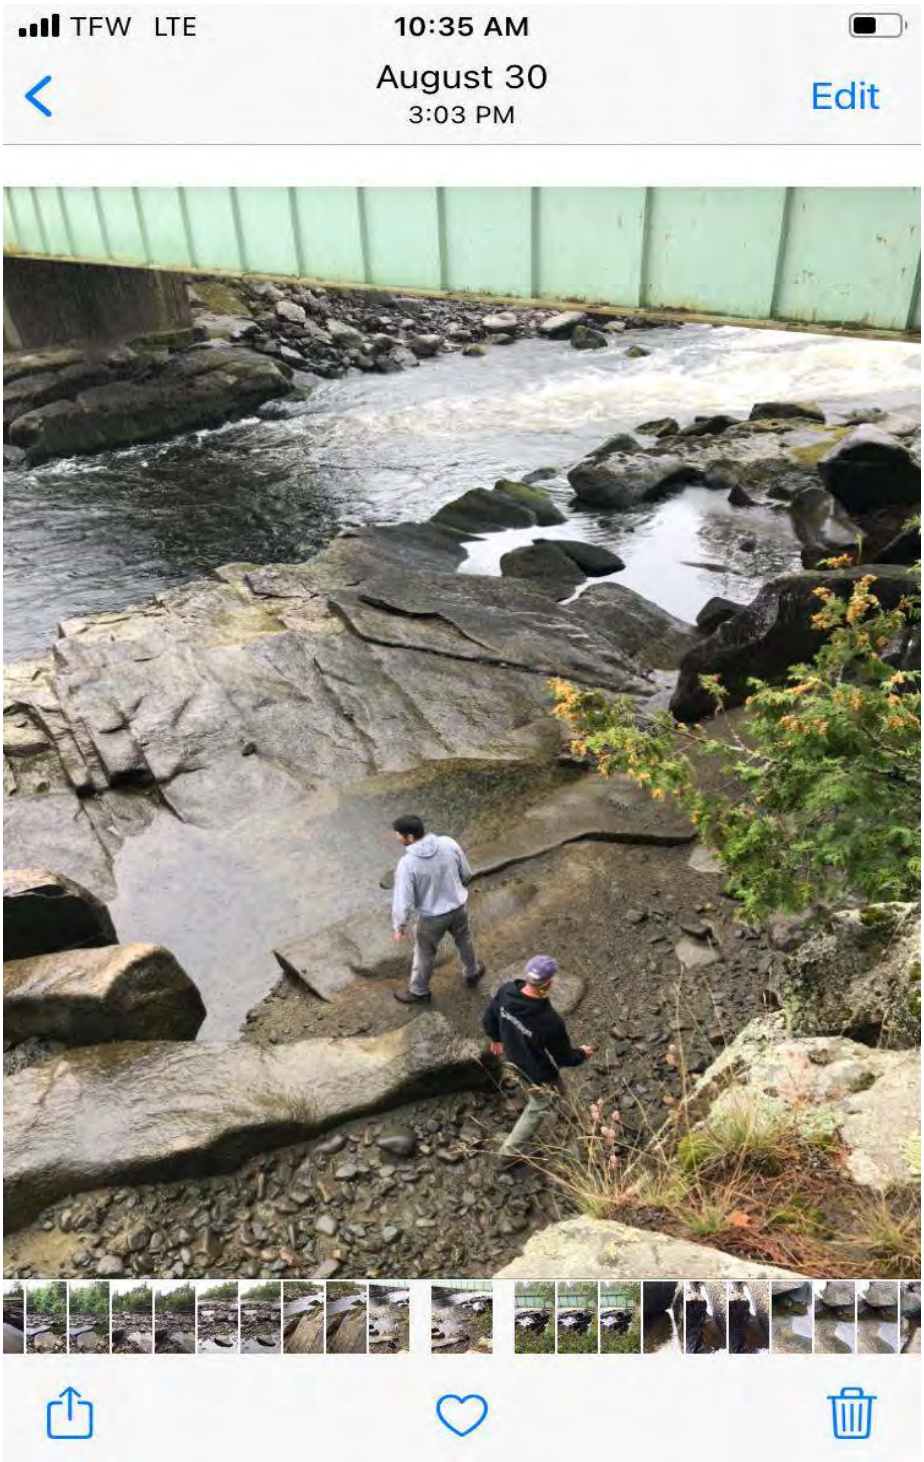
[1] Phone conversation, Stephen Heinz of TU and Alicia Burtner of FERC staff, September 16, 2021.

[2] Brookfield letter Subject: Ripogenus Project (FERC No. 2572); Whitewater Recreation Minimum Flow Excursion dated September 20, 2021, FERC Accession number 20210920-5168.



[3] FERC letter of November 8, 2021, Subject: Violation of Whitewater Recreation Flow – Article 402.
*"… at the Ripogenus Hydroelectric Project No. 2572, located on the West Branch Penobscot River in Piscataquis County, Maine. For reasons discussed below, we find you in violation of Article 402 of your project license."*

[4] Brookfield letter of December 8, 2021, Subject: Ripogenus Hydroelectric Project (FERC No. 2572-133) Penobscot Mills Hydroelectric Project (FERC No. 2458-247) Proposed Study Plan Meeting Agenda



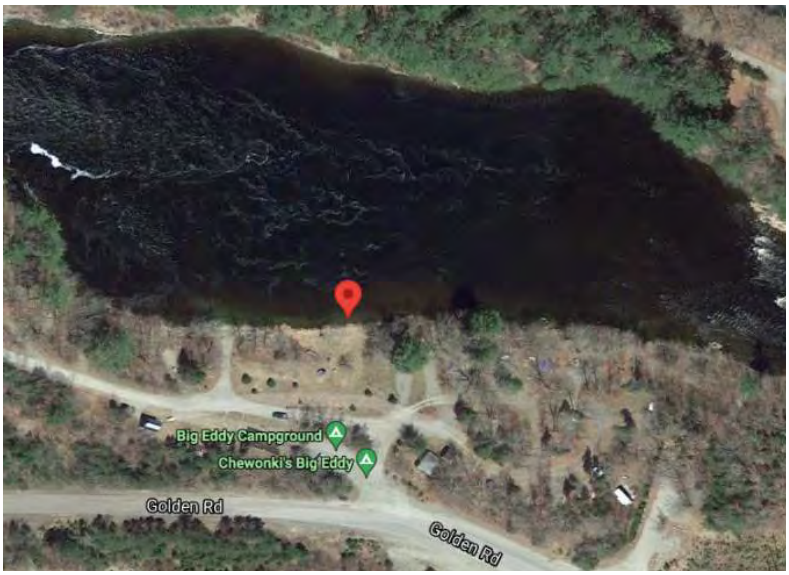
Flow Excursion Study that would conduct a planned low flow event with observers positioned downstream of McKay Station to see if strandings occurred. Miles contacted TU to say that he had a fish stranding photo taken during the August 30 event and macro-invertebrate stranding photos for the September 16 event. He also reported an additional low flow event that occurred on September 7, 2021 that we will address later in this document.

**Strandings Photos**

The photographs below were taken by Miles on the north bank of the West Branch of the Penobscot River immediately below Telos Bridge on August 30, 2021. He has verified that the date/time markings are correct. This map shows the exact location where the photos were taken:

The photo that follows on the next page was taken by Miles looking down at the river from the bank above and includes fellow kayakers Riley Adams and Bill Dallam.

Subsequent photos are of the pool to their immediate left. Please note that the place where they are pictured standing had been running at whitewater flows prior to the event that cause that reach to be classified as Class 5 whitewater. Rapid drops in water level have are likely to strand fish. Miles kayaked to check for other stranded fish and observed about 8 - 12 other stranded fish during this event with four fish specifically noted in a pool just above Holbrook. It is difficult to see stranded in pools, more difficult to photograph them.



Here is a photo of the pool, it is difficult to see the stranded fish that it contains.

Here is the stranded fish. It is a landlocked salmon estimated at 12-13” in length. It was likely stranded in the pool for about three hours.

Here is are the map location and photos of a stranded macro-invertebrates taken during the September 16 event as video that may be viewed at https://drive.google.com/file/d/1KNQf-OzvoG2Lcrq_F2rdDitD3JyHB2I5/view?usp=sharing Numerous other stranded macro-invertebrates were also observed in the vicinity of the campground.

**Additional Low Flow Event**

Miles also reports that a previously unreported low flow event occurred on September 7. This flow was lower than evening flows had been and is estimated to be 800 cfs or less. This occurred at about 6:30 p.m. and persisted for about an hour. The photo that follows the map was taken looking downstream from where Holbrook joins the West Branch on the south bank. The location where the photo was taken is depicted on this map:

The following summary of incidents is provided for clarity:

- August 30 - reported by Maine TU Council filing dated September 21, 2021
- September 7 - previously unreported event (photo immediately above)
- September 10 - reported by Brookfield, ruled a license violation by FERC
- September 16 - reported by Maine TU Council filing dated September 21, 2021

**Ongoing FERC Action**

The photos provided afford additional verification of the August 30 and September 16 events and documents both fish and macro-invertebrate strandings. FERC established a sub-docket for these incidents: P-2572-134. It is assumed that the Commission is continuing to investigate the low flow events of August 30 and September 16, 2021; we assume that the information contained in FERC's filing of December 29, 2021 (bold supplied) will be considered when it rules whether these events constitute license violations as well:

"*Docket(s): P-2572-000*
*Filing Type: Part 12 Consultant Safety Inspection Reports*
*Description: Brookfield Renewable submits 11th Part 12D Independent Consultant's Safety Inspection Report and associated* ***Potential Failure Mode Analysis Addendum for the Ripogenus Project*** *under P-2572. "*

This casts doubt into our minds as to if the corrective actions Brookfield took in 2015[5] to prevent flows below 400 cfs that we noted in our initial report were fully effective.

**Additional Considerations**

FERC Project Officer commented during the PSP teleconference previously referenced that TU's proposed Ripogenus Flow Excursion Study should not be conducted until it the frequency of such events were determined. Apparently, there were at least four events that occurred in a three-week period during August and September of 2021. This amplifying report documents that strandings did occur incident to the August 30, 2021 event and September 16, 2021 event. This report confirms that low flows associated with generator shut downs cause stranding events lasting for over an hour at the least due to travel time for maintenance crews from Millinocket to McKay Station, and were of a longer duration in these specific incidences. We hope that the operator will take the consequences of these events to aquatic organisms into consideration and include the requested Ripogenus Flow Excursion Study in its Revised Study Plan. While these events are not of the magnitude of dewatering of the Upper Madison River in Montana due to a dam gate malfunction,[6] these events have been occurring for some time and studies to determine the magnitude of their impacts below Ripogenus Dam are long overdue.

**Conclusions and Request**

Maine TU Council appreciates the Commission's continuing attention to the low flow events below Ripogenus Dam.

We request a copy of the Brookfield Renewable 11th Part 12D Independent Consultant's Safety Inspection Report and associated Potential Failure Mode Analysis Addendum for the Ripogenus Project under P-2572, Accession Number 20211229-5198, especially the addendum.

We believe that this filing bears on the study requests for the relicensing of the Ripogenus Project and have cross-filed this letter to docket P-2572-133.

Re: Fisheries Studies, Penobscot Mills Hydroelectric Project (FERC No. 2458)

Comments on Great Lakes Hydro America's December 21, 2021 Filing, *a copy of the Proposed Study Plan Meeting Presentation for the Ripogenus and Penobscot Mills Hydroelectric Projects under P-2572, et. al.*

Dear Secretary Bose, Via FERC E-filing

Following the December 15-16 Proposed Study Plan (PSP) virtual meeting, Great Lakes Hydro America (the Licensee) reposted its study Plans. Despite extended questions and answers, there were no noticeable changes. This is disappointing. The PSP is silent on the cold water salmonid specie(S) to be evaluated in studies of the by-passed historic West Branch of the Penobscot River Channel (WB channel). In prior filings Brook trout (trout) were suggested as the cold water study species. Discussions during the December 16 meeting focused on trout but included landlocked salmon (salmon), the only "cold water" species presently found in the tailwaters of the project facilities.

At this time the Licensee is proposing only two studies that directly bear on Penobscot Mills Project fisheries (and none for the WB below McKay Station!); salmon passage into possible North Twin Impoundment spawning tributaries and a flow study of the WB channel. Neither study meets the PSP criterion of identified "data gaps". I also find the choice of studies, methods and (fisheries) goals confusing. While I understand that we are early in the process, some clarity is needed. I left the December 16, 2021 online meeting with the impression that trout were the cold water species to be evaluated in WB channel flow studies. This would be a mistake.

The Preliminary Application Document (PAD) states "*GLHA maintains that a full suite of new studies is not needed, that the vast body of information on which*

*today's certifications and licenses are soundly based and should be relied upon for these relicensing's"*. Yet only two of the agency and stakeholder requested studies were "accepted" by the licensee and these are in areas where ample existing data exist. In both cases, proposed studies focus on physical factors e.g., gradient, substrate and in the case of the WB Channel, instream flow.

Salmonid access to North Twin Impoundment spawning tributaries was well documented in the 1992 application (Vol IX Appendices pp 57-61). Electrofishing of all possible tributaries' during the late 1980s identified only two salmon spawning areas and no potential impediments; Nahmakanta Stream and the WB as it flows into Ambajesus Lake. As there have been no major geographical upheavals e.g., earth quakes, rock slides, the stream beds have not changed. Fish passage remains a function of flow rather than lake level management. Adult salmon telemetry studies will however, provide useful behavior information, including spawning escapement and post spawning survival, and possible movement in the Joe-Mary watershed.

The proposed flow study of the WB channel is also redundant. There have been no major geological changes, the gravel, rock, and boulders remain as they were in 1987. Data sets collected in 1987 can be used as desired, along with the fish species desired to produce weighed usable area. The only change from the 1987 study is the licensee's proposal (not shown in the December 21, 2021 PSP's slide presentation) is to substitute brook trout (trout) as THE only cold water species to be evaluated. This obfuscatory request makes no fisheries sense and contradicts stated MeDIFW fisheries goals.

MeDIFW participated in the 1987-1988 flow study of the historical WB channel below Stone Dam. MeDIFW concurred with the choice of salmon as the evaluation species and participated in developing **adult Landlocked salmon** HSI curves. At that time existing water temperature regimes precluded trout from consideration, projected temperatures (from Quakish Lake) were considered too high and likely, even higher now given recent climate trends.

MeDIFW in its October 8, 2021 filing in support of trout as an WB channel evaluation species, reversed its 1987-1988 in goal of creating salmon habitat. *"fisheries goals and growing angler pressures in the region"* were cited as the reason. However, 2017-2018 Millinocket Lake winter survey data (November 11,

2021 filing) indicated that fishing pressure has actually declined. Each MeDIFW region has hundreds of ponds and miles of stream to oversee and they do an excellent job of managing the various resources. However, licensing is an evidentiary proceeding and subjective judgement is no substitute for empirical data. It would be helpful if MeDIFW provided annual creel survey estimates of angler use and success in local trout streams located in the massive Enfield Region. This would demonstrate an increase in brook and stream angling pressure and the demand for ten inch trout stocked in the spring or larger, 13 inch trout stocked in October.

Other factors demonstrate the folly of using trout, that other than spawning, require no flow (see attached HIS curves) in stream channels, as the only cold water evaluation species

- There are no nearby riverine trout fisheries for resident fish. In fact, trout are only rarely seen in central Maine rivers and when observed in the "summer", it always near cold water refugia.
- Outflow from Quakish lake is by surface discharge and late spring/summer temperatures greatly exceed those temperatures tolerated by trout.
- MeDIFW manages local riverine areas for salmon and trout have never been reported in creel surveys of waters below the North Twin, Millinocket or Dolby facilities.
- The licensee's May and Fall trout stocking of nearby Millinocket Stream where flows are designed for salmonid species have never produced a holdover trout (one stocked in the spring and recaptured in the fall or a trout stocked in the fall recaptured in the spring).

The same biotic considerations of 1988 remain in place today. These factors are;

- Riverine reaches above and below Stone Dam support fishable salmon populations. Thus, salmon in the WB channel would be expected to provide a similar fishery,
- The area below North Twin Dam has limited spawning and nursey area. Millinocket Stream has a surplus of spawning habitat and reproduction is

poor. Salmon are outlet spawners and under appropriate (split) flows, upstream (North Twin Dam) and downstream (Millinocket facility) mature fish would enter the watered WB Channel with suitable flow. Production of naturally spawned salmon would further support fisheries above and below the WB channel. Juvenile salmon are much more tolerant warm summer flows than any trout life stage.

- Shad Pond has depths similar to Nesowadnehunk Deadwater, which is the major overwintering area for the salmon population in the West Branch below McKay Station (FERC Project P2572). An increase in overwintering habitat would be a major enhancement to the Millinocket Facility tailwater salmon population.
- After ice-out, overwintering salmon could move easily upriver, Grand Falls is NOT a barrier. It is possible, fish passage e.g., Steep Pass, would be required to provide access for juvenile and perhaps adults returning over Stone Dam into Quakish Lake and the upstream WB.

Managing the WB Channel for salmon meets goals set forth in **both current (2002-2021 ) and the (draft)FISHERIES STRATEGIC PLAN 2021-2035. The PAD (5.4.1.1) states the current (salmon management);**

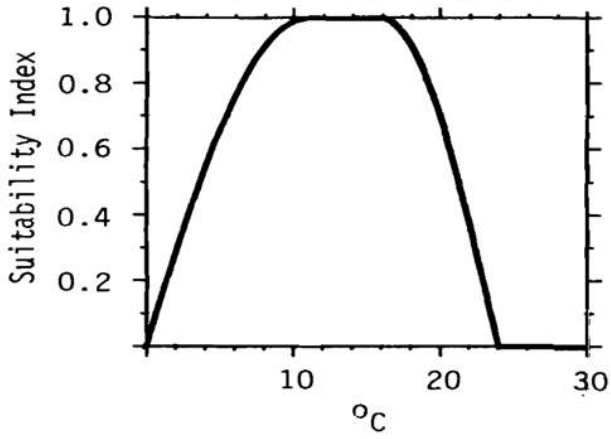
- **statewide management goals for landlocked salmon are to maintain the current distribution of principal fisheries for landlocked salmon, provide for a diversity of fishing opportunities, maintain and where possible expand the contribution of wild salmon to the population**

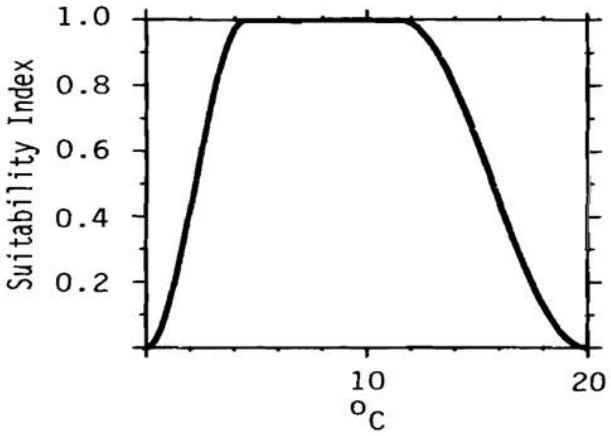
**The 2022 plan adds;**

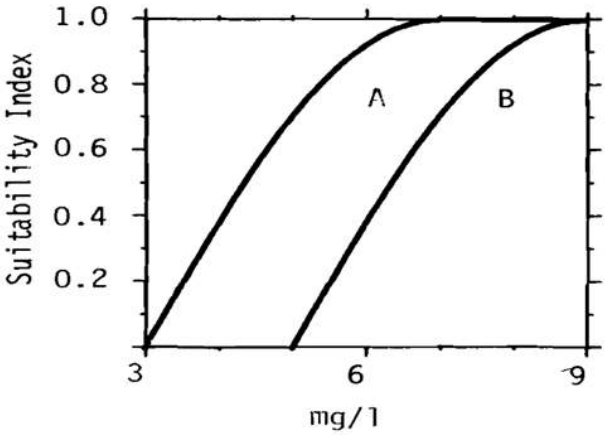
**Maintain or enhance existing (salmon) populations *(High Priority)***

*"Identify potential strategies—including regulation, partnerships, habitat modification, ….."*

***Maintain healthy and sustainable landlocked Atlantic salmon fisheries***







*"Advocating for in-watershed land and water management practices that maintain or enhance spawning and rearing habitats for wild populations, where populations are not overabundant*".

The 1996 EIS (section 4.8.2.3) cites a WB channel production of 245 salmon at a flow of 350 cfs and the FERC staff's estimate was probably conservative. Given the current "catch and release" ethic of todays' anglers, riverine salmon populations are constantly caught and released, recycled (e.g., Roach River, East Outlet of Moosehead Lake). Such a WB channel salmon population would produce a catch of 500-600 fish and would partially mitigate for reduced riverine salmon populations and lost fishing opportunity (as these areas are enclosed by imposing fences) below the Millinocket and Dolby facilities. The added benefit of naturally spawned and reared juvenile salmon increases the value derived from WB channel salmon management. Salmon management far out-weighs the indefensible idea of a possible stocked trout program. The proposal of a stocked trout program appears designed to produce low flow(s) in the WB channel rather than practical fisheries management goals that would require higher flows.

It should be clear to Agencies, stakeholders and FERC staff that management of the WB channel for either wild or stocked trout is an impractical fishery goal designed by the licensee to produce a low flow option. FERC should require that all life stages of salmon are included in the forthcoming WB channel flow study.

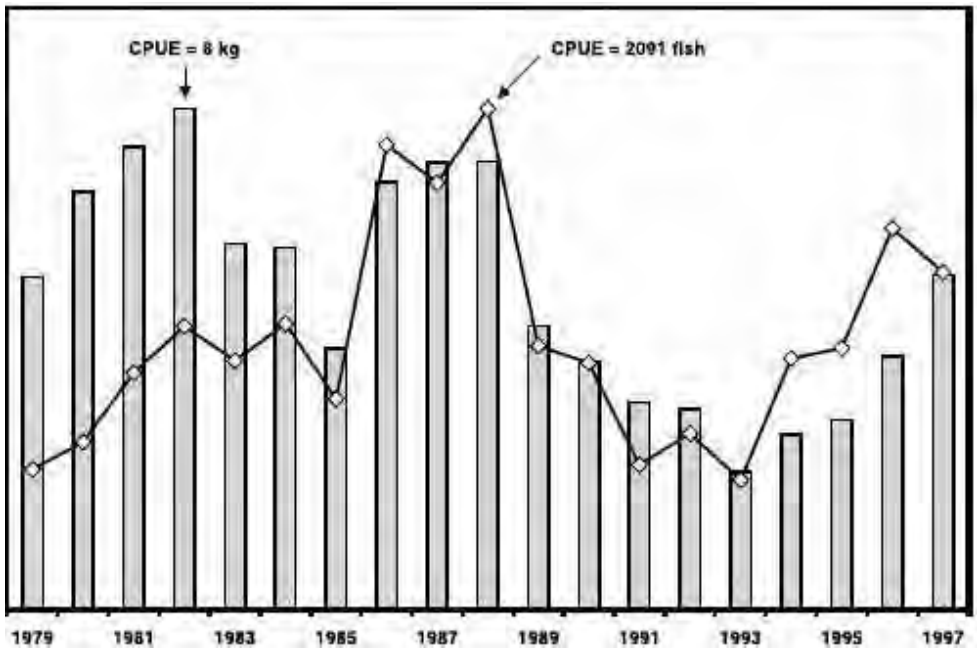
**RE:** A Study Request; The Need to Determine the Status of the Ripogenus Impoundment Zooplankton Population and its Relationship to Larval and Juvenile Rainbow Smelt (Osmerus mordax)

Operations of the Ripogenus Project have changed from the 1996 license conditions of relatively stable base flows and (following) rule curve (storage) guidelines. These flow and lake level changes have significantly altered the observable biotic communities, fish and macro invertrabrates as well as impacting guilds not readily visible e.g., planktonic. Little data exists, but the status of the Ripogenus Impoundment landlocked salmon (salmon) and rainbow smelt (smelt) populations is, as explained below, appalling. Information concerning planktonic communities of the Ripogenus Impoundment and West Branch of the Penobscot River below McKay Station (West Branch) is desperately needed. FERC staff, agencies and stakeholders require current data to make informed decisions.

The Maine Department of Inland Fisheries and Wildlife (DIFW) conducted surveys of the Ripogenus Impoundment landlocked salmon (salmon) fishery during 2018-2021. These salmon growth, food habitat and general abundance studies demonstrated a fishery in decline; adult salmon were fewer and in poor condition. DIFW cited the lack of young of the year (YOY)/Age I smelt as the problem. These small (2-5 inch) smelt are suitable in size as salmon prey. Age II and older smelt are generally too large to be useful prey items for adult salmon. Similar YOY smelt trends exist in the West Branch where salmon growth is well below 1980s levels and smelt are generally absent. To their credit DIFW responded to the depressed Ripogenus salmon fishery by increasing the harvest of sub adult and adult (>12 inches) salmon. The goal was to increase the Ripogenus YOY smelt population by reducing salmon predation, thus allowing the smelt population(s) to recover. This strategy has yet to prove successful. Peer

reviewed literature demonstrates that salmon predation on smelt is an unlikely cause of the continuous (10-15 years) lack of juvenile smelt.

There are NO current data on the growth and abundance of smelt, phytoplankton or zooplanktons population in the Ripogenus Impoundment. To date, attempts to reduce the Ripogenus salmon population have failed to rejuvenate the smelt forage base. DIFW has stated that angler effort is not at the level needed to reduce the adult salmon population. While angler harvest offer possibilities in rebuilding smelt populations, there are better alternatives. A review of journal articles demonstrates that lake level management is the likely cause of a depressed/altered zooplankton community that has resulted in a depleted juvenile smelt forage base over the last ten plus years. These reasons all involve the abundance and structure of zooplankton populations. The cause and effect of lake level management e.g., timing of drawdowns, depth, temperature and fluctuation/compression of the littoral zone, lack of connectivity (between basins) need to be explored.



Smelt are vital forage species and in some areas also a hook and line or dip net fishery. Smelt are well distributed throughout the Northeast, Midwest (Kircheis and Stanley 1981) and Northwest where they exist as the sub species, *O. dentex*,. Because of their role as both a forage and table fish; smelt abundance, prey selection and habitat preference have been well studied. Without smelt as prey salmon populations collapse and cease to provide a fishery (Havey and Warner 1970).

A 1981 summary by Maine research biologists Fred Kircheis (MeDIFW) and Jon Stanley (UMO Coop Fish Unit) reviewed smelt populations in Maine and other Lakes throughout the Northeast. Regarding variability in smelt population abundance/densities, they concluded that *"such fluctuation are usual and do not appear related to predator abundance, rainbow smelt fishing or disease." Rainbow smelt larvae require small zooplankton such as rotifers when they begin feeding, "unavailability of suitable size plankton might limit survival of larvae" (McCullough and Stanley, 1979)."* (Kircheis and Stanley 1981). The literature provides insight into a litany of factors determining smelt abundance and growth.

Based on extensive review of the literature, the primary reason for a reduction in larval/juvenile smelt year class is cannibalism by age II and older smelt. Smelt are known to demonstrate alternate year class strength, often resulting from cannibalism as well as variable population densities resulting from predation or loss of suitable zooplankton as forage. Stetter et al. (2007) reported cannibalism

at between 38 and 95 percent of YOY year class strength. This cannibalism typically produces alternate smelt years classes where larval survival is poor the first year but strong the next year(s) (Lantry, B.F., and Stewart, D.J. 2000). He and Labar (1994) studying Lake Champlin smelt populations noted that gaps in year class strength could extend for three to five years. The figure below demonstrates smelt year class variability (Mills et al. 2003). These data are from the USA side of Lake Ontario.

**Fig. 6.** Indices of relative abundance (□) and biomass (bars) of age-1 and older rainbow smelt for a 21-year period, 1978 to 1998 caught in trawl tows of 10-min duration in late May – early June in U.S. waters of Lake Ontario. Indices are 3-year running means standardized to the maximum stratified CPUEs (catch-per-unit-effort) indicated. The X axis represent indices of abundance and biomass (0.0-1.2)

As there has been no change in the condition in West Branch salmon in ten plus years and DIFW has found a similar trend in Chesuncook, the lack of smelt has not been a cyclic event. Thus, both over-predation (by salmon) and cannibalism must be dismissed as factors in the ten to fifteen year decline of Ripogenus Impoundment smelt populations.

Depending on age, smelt have different temperature and depth preferences. Rooney, R.C and Paterson, M.J. (2009) provide excellent summaries of smelt life history requirements at life stage and depth. From these summaries we know that "*YOY smelt are eurythermal and are usually found along the shoreline in depths of 7-20 feet. Yearlings become pelagic and move to deeper cooler water at "middle depths in the pelagic zone" unless the epilimnion temperature exceeded 18°C, in which case they congregated just beneath the thermocline" (Appenzeller*

*and Leggett 1995). "Following fall turn over YOY smelt move to deeper water (Urban and Brandt 1993). Age II and older smelt can be found in the littoral zone in the spring but as surface waters warm, are usually distributed in the profundal zone with water temperature ranging for 6-14 C and depths greater than 15 meters." (Nellbring 1989)*. O'Gorman et al. (2000) reported that "smelt were forced into deeper water when Lake Ontario was colonized by exotic *Dreissena* mussels" and prey was reduced in shallower water.

Smelt are dependent on zooplankton and favor "large" bodied prey (including Diptera e.g., midge) and plankton communities can change with season and lake basin. Sheppard et al. (2012) described smelt food preferences in a Manitoba lake. "The Diet of freshwater population of rainbow smelt is generally composed of copepods and cladocerans (including Daphnia spp., Eubismina and Bossmina) (Urban and Brandt, 1993; Hrabik et al., 1998; Beisner et al., 2003; Johnson et al., 2004)". Selectivity of zooplankton prey varies with smelt age (and size). YOY Smelt (larval smelt >30 mm) are dependent on zooplankton and without suitable prey, populations collapse. Hrabik et al. (1998) described calanoid copepods as "favored prey". Age I and older smelt favor larger prey. Karnitz, J (1992) studying Lake Oahe Plankton found "Rainbow smelt prey were significantly larger than mean size of zooplankton in the environment" and that feeding increased with water temperature.

Zooplankton species composition can very between lake basins. Zooplankton communities in Lake George differed between two basins. "Large bodies zooplankton species were favored over smaller size species. Daphnia pulicaria that were dominant in one basin and were generally absent in the other basin where Mysis relicta was the dominate smelt prey item" (Siegfried, C. 1987). *Mysis* was most important in rainbow smelt diets in Western Lake Superior where smelt were again reported to choose larger taxa. Johnson et al (2004) reported a shift in species from prior studies of the Lake Superior zooplankton communities. Johnson, B.M., and Goettl, J.P. (1999) studying Horsetooth Reservoir smelt predation on zooplankton found "during 1989–1994 the abundant rainbow smelt population apparently reduced April and May crustacean zooplankton concentrations from historical levels of 40–80 organisms/L to less than 1.0 organism/L, and a switch occurred in the cladoceran species composition." In later years the smelt population declined and the zooplankton community rebounded. Other authors referenced declines in zooplankton abundance resulting from piscivorous predation. And while there were shifts in taxa, in all cases, zooplankton populations returned to prior levels.

The above paragraphs provide compelling evidence of the relation between the abundance, suitability and availability of zooplankton populations as prey as related to smelt abundance and survival. The collapse of the Ripogenus Projects zooplankton-smelt prey relationship has been long-term, perhaps fifteen years.

The exact mechanisms that created depressed zooplankton and Juvenile smelt declines in the Ripogenus Impoundment are unknown, but they are directly related to lake level management. Loss of shallow embayments (as hatchling habitat), compressed or shifting littoral zones reduce or eliminate critical larval or YOY smelt habitat, thus favoring older (and larger) age classes that prefer deeper water. These same factors apply to zooplankton communities that may have changed to meet altered intra species competition, food sources (phytoplankton) or micro habitat needs: depth, temperature, light (Appenzeller, A .and Leggett, W. 1995, Emery, A.R. 1973).

The status of the Ripogenus plankton population(s) needs to be defined. Zooplankton surveys need to be included in Ripogenus Impoundment water quality studies recommended by MeDEP. If used in conjunction with other water quality sampling events the collection costs are minimal. Fine mesh plankton nets can be “towed” behind the boat used in sampling Ripogenus Impoundment basins. The Caribou basin should be included in zooplankton sampling. Data collected in 2022 can then be compared to studies conducted in 1981 (see tables below; Vol VIII 1991 Rip Application). Locations, timing and methods of the 1981 Ripogenus Impoundment zooplankton surveys can be found in Volume VIII of the 1991 license application. To “fill in data gaps”, FERC needs to require similar studies as part of the MeDEP October 2021 Water Quality Study request.

Historically the Ripogenus Impoundment supported an excellent salmon fishery and the Impoundment’s smelt population was exported downstream (“drift”) through McKay Station where it created and then supported the “world class West Branch salmon fishery”. DIFW filings have demonstrated that these fisheries have collapsed. Echoing earlier works of Havey and Warner (1970), the DIFW 2012 management plan states, “Without adequate numbers of smelts, salmon growth and condition can become poor, markedly reducing their value as a sportfish” (Maine Salmon Management Plan. 2012). Without the export/drift of smelt, the West Branch fishery will disappear. FERC needs to ensure these two unique fisheries are returned to 1980s levels described by FERC staff in the 1996 EIS.

Katie Stopera, Watertown, MA.
Save the fish!!!

Bring our lake levels back

Peter Stopera, Hollis, NH.
I’ve spend the past 40+ years on Caribou Lake (long green camp) fishing every year. The zooplankton can not survive, this management of the lake is killing a beautiful piece of America, which will be forever lost.

Fishing has been lousy for past several years, I kept on thinking I’m doing something wrong. Hopefully we can get our lake level back

My wife and are older now and spend about 1 month of the year at the lake, there is no running water. We need to use lake water to do our dishes (we have a Grey Water system). This past years and several years before we are literally walking 1000 feet across rocks, just to get 2 buckets of water.

Navigating on Caribou lake is now treacherous. In 2021, we could not get to Chesuncook lake from Caribou lake.

Terry Stopera, Hollis, NH.
Save the fish!! Save the loons!!

I’ve been going to Caribou Lake for almost 50 years and have never witnessed back to back years with the lake so deathly low. This can be changed.

Please help preserve the environment, bring back our lake levels.

Project: MHPC# 1049-21 — FERC 2572-133 Ripogenus Hydro; FERC 2458-257 Penobscot Mills Hydro
Scoping Document

Town: Various, ME

Dear Secretary Bose:

I am writing to provide some clarification to our August 30, 2021 letter regarding the scoping document for the Ripogenus Hydroelectric Project (P-2572-133) and Penobscot Mills Hydroelectric Project (P-2458-247)" which was received in our office on August 19, 2021.

Archaeological survey is currently being undertaken for this project. However, the scope document does not adequately address cultural resources including archaeological sites around the impoundment margin and any architectural resources within the impoundment area.

Our office stands by our June 29, 2021 recommendations for architectural and archaeological surveys (see attachment).

Please contact Megan Rideout at (207) 287-2992 or megan.m.rideout@maine.gov if we can be of further assistance in this matter.

Sincerely,

Kirk F. Mohney
State Historic Preservation Officer

**Via online submission to: http://www/ferc.gov (cross-filed)**

Subject: **Preliminary Comments on the Proposed Study Plan (PSP) for the Ripogenus Project (P-2572) and the Penobscot Mills Project (P-2458)**

Dear Secretary Bose:

The Maine Council of Trout Unlimited ("TU"), Appalachian Mountain Club ("AMC"), American Whitewater ("AW"), Caribou, Chesuncook Lake Camp Owners Association, Chesuncook Dam Camp Owners Association, the Allagash Gateway Campground, and Andre Emerson Cushing Corporation file these comments to address our underlying concerns regarding the current status and direction of the relicensings of the Ripogenus Project (P-2572) and the Penobscot Mills Project (P-2458) being undertaken by Great Lakes Hydro America, LLC for Brookfield Renewable ("Brookfield") or ("Applicant"). Brookfield filed its Proposed Study Plan on November 22, 2021. While each of our organizations intends to file separate comments in response to specific study requests, we are providing these comments to voice our shared concerns regarding the manner in which Brookfield has approached the relicensing process to date.

**Background**

Maine Council of Trout Unlimited represents six local chapters with over 2,000 fisher-conservationists in Maine. The mission of the organization is to bring together diverse interests to care for and recover rivers and streams so our children can experience the joy of wild and native trout and salmon. The entire watershed of the West Branch of the Penobscot is especially important to a great many of our members who enjoy its fishing resources, including the area from McKay Station to Nesowadnehunk Falls, Ripogenus-Chesuncook-Caribou Lake, and the waters below to its confluence with the main stem of the Penobscot River that are greatly affected by the Ripogenus and Penobscot Mills projects.

Since 1876, the Appalachian Mountain Club has promoted the protection, enjoyment, and understanding of the mountains, forests, waters, and trails of the Appalachian region. AMC is the largest conservation and recreation organization in the Northeast with more than 90,000 members, supporters, and advocates, many of whom visit the lands and waters upstream and downstream of the projects for recreation.

American Whitewater is a national non-profit 501(c)(3) river conservation and recreation organization founded in 1954. With approximately 6,000 members and 100 affiliate clubs, representing tens of thousands of whitewater paddlers across the nation, American Whitewater's mission is to protect and restore our nation's whitewater resources and to enhance opportunities to enjoy them safely. Our members are primarily conservation-oriented kayakers and canoeists, many of whom live and/or engage in recreational boating in the New England region within reasonable proximity to the West Branch of the

Penobscot River. American Whitewater has long been involved with the FERC licensed hydropower projects in Maine, including hydropower projects located on the Penobscot, Kennebec, Rapid, and Magalloway rivers, and is party to settlement agreements that provide for whitewater boating opportunities that partially mitigate for project impacts. We highly value the whitewater activities offered by the West Branch.

The Caribou and Chesuncook Lake Camp Owners Association and Chesuncook Dam Camp Owners Association represent the interests of those with property on the shores of these lakes who have been greatly affected by the severe dewatering of the Ripogenus-Chesuncook impoundment in recent years.

Allagash Gateway is a four-season sporting camp located on Ripogenus Lake near the Chesuncook Dam Point Boat Launch. It offers a private boat launch, canoeing, campsites, lodging, guide services, and a small store. During the summer months, Allagash Gateway's clientele is primarily interested in boating and fishing the lakes that make up the Ripogenus impoundment. Operations of the campground have been profoundly impacted over the last few years by the water levels of Ripogenus Lake and Chesuncook Lake.

Andre Emerson Cushing Corporation is the majority landowner in T3 R12 WELS. Approximately 80% of Ripogenus Lake and 20% of Chesuncook Lake are within the boundaries of T3 R12 WELS. William Cushing, a director of Andre Emerson Cushing Corporation, is a year-round resident of T3 R12 WELS, and his home is on Ripogenus Lake.

**The Problem**

Brookfield devotes pages of the Pre-application Document (PAD) to the assertion that: "*GLHA maintains that a full suite of new studies is not needed, that the vast body of information on which today's certifications and licenses are soundly based and should be relied upon for these relicensings. In addition, consistent with the Commission's criteria for study requests, the scope and extent of any new study be focused on addressing specific data gaps necessary to inform the development of license requirements."*[1] The PAD goes on to explain: "*These PM&E measures comprehensively address resource interests specific to the Project areas, as well as the larger river basin. These interests include water quality; management and balancing of flows within and downstream of the West Branch; aquatic and terrestrial resources; whitewater and recreational opportunities; cultural resources; and land management*."[2] The implication is that these measures remain fully adequate when they are not. The PSP states: "*Based on the totality of studies conducted, settlement agreements reached, PM&E measures incorporated, and water quality certifications issued, FERC's 1996 licenses concluded that the Projects are best adapted to serve the public interest. GLHA maintains that nothing has significantly changed that would alter this conclusion."*[3]

These assertions could not be more wrong and started the relicensing off on the wrong foot. A glaring example: The Ripogenus-Chesuncook impoundment has not been fully watered in two years, and the boat launch provided as PM&E has been so far from the waterline for most of the summers so as to be practically unusable, as many photos have clearly shown. The public interest has vastly changed since the last relicensing. Agencies bent over backward to ensure the profitability of the mills in East

[1] Brookfield Notices of Intent and Pre-application Documents for the Ripogenus Project (P-2572) and the Penobscot Mills Project (P-2458) dated June 11, 2021, page 1-11.

[3] PSP, pages 11-12.

Millinocket, the major employer in the area, that were supplied by power the projects provided. If that were not the case, the Use Attainability Analysis (UAA) and the provisions of 38 M.R.S.A. § 464(9-A) would not have allowed so much leeway for project operations, e.g., no minimum drawdown for the Ripogenus-Chesuncook impoundment other than the lowest levels the physical characteristics of Ripogenus Dam allow. Other examples included the dewatered Ripogenus Gorge on the main stem of the West Branch below Ripogenus Dam and 4.5 miles of the main stem below Stone Dam. **It is highly unlikely that these examples would have been permitted under the last relicensings were it not for economic considerations that simply no longer exist.** With the mills closed and the electricity produced by the projects going to the grid and not dramatically affecting the economy of the region, the situation has changed greatly, and that change needs to be acknowledged for the relicensing process to proceed effectively under the ILP. Brookfield should acknowledge this fact or include the request for a socio-economics study submitted by the Penobscot Indian Nation[4] in its Revised Study Plan.

Brookfield is required to provide FERC with information in the PAD and PSP referencing either relevant and recent existing studies or proposing new studies that address a number of subject areas including: Fish and Aquatic Resources, Recreation and Land Use, Aesthetic Resources and Tribal Resources. Instead, Brookfield relies on dated, unavailable, or non-existent studies or directs stakeholders to search for the information themselves at other agencies or on the Internet. Examples: Fisheries Resources - including "*Species life stage composition*"[5] were provided by referencing data some of which is over 30 years old. During the PSP teleconference, Brookfield referred the requirement to the Maine Department of Inland Fisheries and Wildlife. It is not the Department's requirement to provide the information, it is the Applicant's obligation, and the data still has not been fully provided for all projects' reaches except by references to a number of studies of varying ages. Recreation and Land use was nearly ignored, and we fail to understand the relevance of Brookfield's reference to "*Existing shoreline management policies*"[6] for an impoundment that has not been fully watered for two years and where the waterline has generally been hundreds of feet from the boat launch it accesses. There are many recreational amenities not in the project area that are well known and frequently used that will not be considered by forthcoming studies. The accepted information and study standards are simply being ignored.

The key studies are the flow studies proposed by the National Marine Fisheries Service (NMFS); key information is the ten years of operational data requested by the National Marine Fisheries Service (NMFS) There is no USGS flow gauge above the Medway Project nearby to the confluence of the West Branch with the main stem of the Penobscot River. Brookfield has been reluctant to release operational data that would reveal flows. Brookfield clearly has this data and has provided it to FERC Compliance Division on a number of occasions when reporting flow excursions. There was some discussion during the PSP Teleconference of delaying the requirement for a project operations and flow monitoring plan until after the new license is issued. This would make the relicensing process itself nearly meaningless. Over 50 years have passed since the passage of the Clean Water Act. Our nation's waters now run clean but too many still lack the indigenous aquatic organisms due to dams and lack of access to critical habitat. The dams on the West Branch will remain for the foreseeable future. The task of relicensing is to manage the resource most effectively to support all uses including power generation, ecology, recreation and aesthetics. Flow data is essential to the relicensings of both projects. It has been available all along and should have been offered with the PAD. While Brookfield has stated that it will provide

[4] Penobscot Nation letter dated October 12, 2021, RE: Penobscot Mills (P-2458-247) and Ripogenus (P- 2572-133) Notice of Intent, Pre-application document, Scoping document #1 and study requests

[5] Id., page 5.

[6] Id., page 6.

some flow data with the RSP, this will not provide stakeholders with sufficient time to analyze and comment on data that Brookfield has yet to provide.

The Integrated Licensing Process is intended to "s*treamline the Commission's licensing process by providing a predictable, efficient, and timely licensing process that continues to ensure adequate resource protections.*" To date, any reasonable analysis of Brookfield's participation in the Ripogenus - Penobscot Mills relicensing process indicates that Brookfield is attempting to delay and confuse the process by failing to provide the data required by FERC with the PAD, and then rejecting study requests involving the data.

**The Commission's Opportunities**

The FERC process has developed over the years to provide an orderly process leading toward licensing or relicensing of an energy project. 18 CFR § 5.6 clearly defines what information the applicant should provide in the PAD. Instead of providing it, Brookfield referenced studies conducted over 30 years ago and proposed to fill "data" gaps. Stakeholders submitted requests for the information in their PAD comments; Brookfield's response was to concentrate on the study requests and instead of providing the requested information in a usable form, to provide or reference old studies. This is not how relicensings are generally conducted under the ILP, whether or not the relicensing is the first conducted after passage of Electronic Consumers Protection Act (ECPA).

We appreciate FERC staff's recognition that the terms "dry way" and "back channel," used by Brookfield to refer to dewatered sections of the main stem of the West Branch, are inappropriate. We also applaud SD2 as a significant step in the right direction and expanding significantly on the limited scope that Brookfield had proposed. Brookfield's response was to issue a Proposed Study Plan that only accepted three studies as submitted. In a number of cases, studies are rejected that are clearly indicated by the SD2 as within the scope of FERC's planned NEPA analysis, yet Brookfield is not committing to completing studies that will address the data gaps and scope provided by SD2. For example, SD2 identifies that the NEPA analysis will seek to understand the effects of the projects on angling access/opportunities on the project impoundments, yet the PSP provides for no methodology or approach within the recreation study to specifically survey or assess the impact to and quality of angling on the impoundments and this information cannot be ascertained solely through spot counts and a facility assessment. Comparable, SD2 indicates that the NEPA analysis will assess the effects of the projects on angling opportunities for landlocked salmon and brook trout in the riverine reaches, which cannot be adequately assessed using the PSP's methodology which includes only site assessments and spot counts.

Furthermore, in arguing that study requests lack a nexus to project effect, the licensee relies on the *Centralia* decision (*City of Centralia v FERC*, 213 F.3d 742, 749 (D.C. Cir., 2000)) to argue that certain studies are an attempt to search for a problem where there is no evidence that problem exists. The licensee's reliance on *Centralia* is misplaced. That case concerned a post-license study of the need for a tailrace barrier net where there was substantial evidence in the record that the barrier net was unneeded. There the court found that the project effects of the discharge on fish were entirely speculative. Similarly, in *City of Jackson, Ohio*, 105 F.E.R.C. ¶61,136 n.9 (2003), a FERC decision on which the licensee relies, likewise involved a post-license study to assess whether the project was having an adverse effect on fisheries resources. This decision is inapplicable to circumstances such as are present on the West Branch of the Penobscot where the effect of the project on a protected resource is clear and the study is designed to evaluate the extent of that impact so that FERC can complete its NEPA review based on its scoping document. *FPL Energy Maine Hydro, LLC*, 95 F.E.R.C. ¶61,106 n.15 (2001)

and *Allegheny Energy Supply Company, LLC*, 109 F.E.R.C. ¶61,028, 61,117 (2004), also cited by the licensee, likewise involved the need for a license condition requiring a post-license study of project effects on fish. Each of these cases is inapposite to the study requests on the West Branch.

The licensee endeavors to extend the holding in *Centralia* and subsequent FERC decisions to argue against requiring studies *during* the pre-application phase of the Integrated Licensing Process (ILP) to limit the information available to FERC for its NEPA analysis. FERC's nexus requirement in its study criteria was not intended to create a barrier to study of project effects on resources that are within FERC's power to address in a license condition. In effect, the licensee's circular logic would require prior study in order to justify the need for a study while prior study makes the need for a study unnecessary. To meet FERC's nexus criteria, a proposed study need only show that the project has a direct or indirect effect on a non-developmental resource that will be evaluated by FERC as part of its environmental assessment. This Catch-22 scenario was certainly not what Congress intended when the Electric Consumers Protection Act amended the Federal Power Act to require that FERC "shall give equal consideration to the purposes of energy conservation, the protection, mitigation of damage to, and enhancement of, fish and wildlife (including related spawning grounds and habitat), the protection of recreational opportunities, and the preservation of other aspects of environmental quality." 16 U.S.C. § 797(e).

The circumstances surrounding the *Centralia* decision are different from those surrounding the Ripogenus - Penobscot Mills relicensings. Brookfield has applied the phrase "*where evidence of a problem has not been shown"* to a number of study requests. The dewatering large areas of Maine's third largest lake for months at a time, dewatering its most dramatic gorge or a 4.5 mile section further downstream, or abruptly reducing flows from about 2000 cfs to 400 cfs or lower stranding fish and macro-organisms in the process, provides ample evidence that a problem exists.

**Conclusion and Requests**

Accordingly, we ask that:

- FERC require that Brookfield address these comments when evaluating each stakeholders' individual Proposed Study Plan Comments, and offer a Revised Study Plan that will inform the process with current information.

- FERC review the applicant's revised study plan immediately after issuance to ensure that all scope items included in SD2 will be adequately assessed in the proposed studies and that the revised study plan include methodologies that will close all data gaps. Should any gaps continue to exist between the scope of the NEPA analysis and the studies proposed by the applicant, FERC should require the applicant to update the revised study plan, before stakeholders are required to comment on the revised study plan.

- FERC staff consider these comments in making its Study Plan Determination and insist on a suite of studies that will inform the process in accordance with FERC guidelines pursuant to 18 CFR § 5.6 and avoid larger problems later in the relicensing process.

- FERC staff extend the deadline for comments on the Revised Study Plan to 60 days to allow the public to provide additional comments based on operations data and other information provided in the RSP that was not provided with the PSP.

Our organizations appreciate the opportunity to provide these preliminary comments on these important projects and hope that the Commission will act to allow the resource protection agencies to obtain a range of studies that can identify potential harms to the resource and thus enable the Commission to balance project harms and benefits.

Subject: A study Request; Ramping and the Need to Determine the Appropriate Rate of Flow Change Below McKay Station on the West Branch of the Penobscot River.

GLHA's PAD issued June 11, 2021 states "there have been no changes to Project operations". Regarding the 1996 License and FERC conclusions on the status of fish and aquatic communities "GLHA maintains that nothing has significantly changed that would alter this conclusion." GLHA continues its pipedream/negotiation strategy by stating "GLHA maintains that a full suite of new studies is not needed, that the vast body of information on which today's certifications and licenses are soundly based and should be relied upon for these relicensing". Given the dramatic change in project operations, other than providing critical baseline information, forty-year-old data is useless in determining the 2022 status of the present fish and aquatic communities and angler use.

To those of us who have stood along the West Branch of the Penobscot River (West Branch) in recent years, GLHA's PAD comments are insulting, as we have witnessed the dramatic flow increases in the mornings followed by sudden decreases in the evenings. The Licensee often references protection, mitigation, and enhancement (PM&E) measures, given the current flow management and ecological degradation, this seems miss-leading and inappropriate. Project operations have changed dramatically and the results are a biological disaster. In order to identify existing fish and aquatic invertrabrates population compositions, many studies are needed and a water use plan needs to be independently developed. The status of fish and aquatic communities as well as angler use, effort and catch are required.

One of the needed studies deals with water management and ramping. A ramping study would determine the rate in which flow can be increased or decreased (over time). Fish and aquatic communities are vulnerable to sudden increases and decreases in flow that disrupt movement and feeding as well as strand fish and aquatic insects at all life stage. Resulting losses have a major impact on the riverine ecosystem. The requirement of studying and then determining ramping rates below all project facilities will benefit fish and aquatic communities.

In my October 1,2021 FERC filing, I provided a number of general comments on stream flow management. Thus, a small part of the following maybe redundant but never the less, the proof of habitat degradation remains highly relevant to river management.

The literature is replete with references on Hydro peaking, sometimes referred to as “pulsed power”. Peaking flows impact both fish, landlocked salmon (salmon), the principle West Branch salmonid, and brook trout as well as macro invertrabrates and plankton. Salmon populations exist in the Northeast, mostly in Maine where they are native (as they are in several eastern Canadian waters). Data base references to salmon and flow manipulation are limited. Brown trout (Salmo trutta) are similar to salmon in life history requirements including habitat and food selection. Thus, some of impacts of flow fluctuation on salmon are based on references developed from brown trout studies.

In Maine, useful information about flow and flow alteration on salmon movement (telemetry) is limited to the riverine area below Harris Station (Indian Pond FERC P-2142). Licensing study results demonstrated lateral movement in response to peaking flow but insignificant up and down stream movement (fish remained near their pre-peaking location). **A Canadian study by of landlocked salmon and trout in a medium size stream (88 cfs) used EMG coded transmitters, Enders et al. (2007). The authors found adult landlocked salmon preferred faster flow and deeper pools in the main channel, and “that fish effectively chose microhabitats that allowed them to reduce energy expenditures associated with movements.” Scruton et al (2011) studied juvenile Atlantic salmon below an experimental hydroelectric station in Newfoundland CA. and reported that altered flows caused behavioral changes. The staterogy of moving to a “microhabitat” assumes suitable habitat exits and is both in proximity and unoccupied. In the**

**high velocity gorge below McKay Station, these refugia/microhabitats are limited.**

**Additional information on peaking and its impact on salmonids provides support for the very limited studies of salmon discussed above. Quinn and Kwak (2011) found brown trout (Salmo trutta) and rainbow trout (Orcorhychus mykiss) were found in velocity refugia near an Ozark river's margin during high flow. Ayllon et al (2008) found that age I+ and older brown trout moved in response to the flow and velocity changes. Lagarrigue et al (2002) found reduced brown trout abundance below a hydro peaking system when compared to an upstream "control site" in the French Pyrénées and noted the shift in brown trout diel feeding activity in response to peaking flows. While numerous studies suggest that peaking operations have little effect on up or downstream movement, lateral movement and habitat selection in response to flow alterations requires energy as well as reducing salmon feeding activity, growth and predator avoidance.**

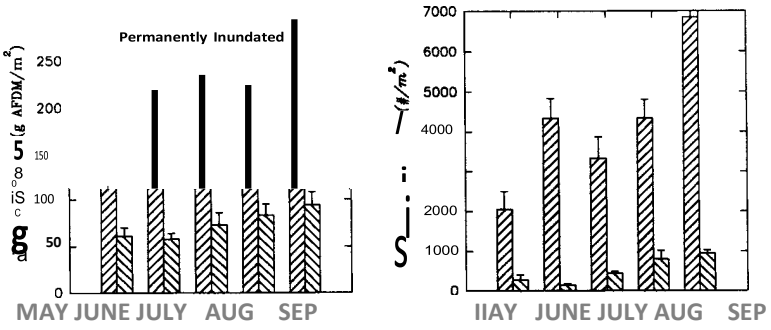
**During the 1992 licensing of Ripogenus Project, Juvenile salmon production was identified as the factor that limited the West Branch adult salmon population. The construction and operation of the Holbrook bypass nursey channel (dewatered many times in 2021) was a license condition (WQC Article 406) designed to mitigate the lack of West Branch juvenile salmon habitat. Present project peaking operations eliminate/reduce juvenile salmon production in both the Holbrook bypass area and all riverine reaches, a PM&E measure lost. Bauersfeld (1978) studying west coast salmon estimated *a 1.5% fry loss per drawdown with a total loss of 59% of the salmon fry population for one season*. Scurton et al. (2011) and Young et al. (2011) echoed similar concerns while Haakon et al. (2021) described the degree of impacts e.g., growth and abundance, caused by various flow changes on Norwegian juvenile salmon in Norwegian rivers.**

**The above paragraphs document the complexities of salmonid life histories as related to peaking flows. Salmonid movement, feeding habitats and velocity refugia need to be identified and incorporated in studies designed to enhance McKay Station biological flow requirements (minimum, peaking). Obviously, understanding of seasonal and diel behavior is also required. It should be noted**

**that the licensee's timing of early morning peaking and early evening sudden reduction of flow coincides perfectly with the timing of (natural) macro invertrabrate drift (currently, this timing is unknown) and peak salmonid movement and feeding activity.**

**Not discussed in the above fisheries references are the West Branch anglers. Present operations and hydro peaking limit the physical process of fishing e.g., drift boat, canoe or wade fishing, as well degrading the condition and abundance of salmon (and brook trout). From my many trips to the West Branch in the last few years, there are fewer anglers. Those anglers fishing from July though September were concentrated in the reach between McKay Station and the Big Eddy. Any ramping study should evaluate angler use and fishing opportunity.**

**The Literature is replete with reference to peaking flow and impacts on macro invertrabrates communities and plankton. Angradi and Kobly (1995) referenced dewatering impacts on the epilithon (algae, plant matter) in the Colorado River. As shown below, repeated dewatering reduced the food source of macro invertebrate grazers.**



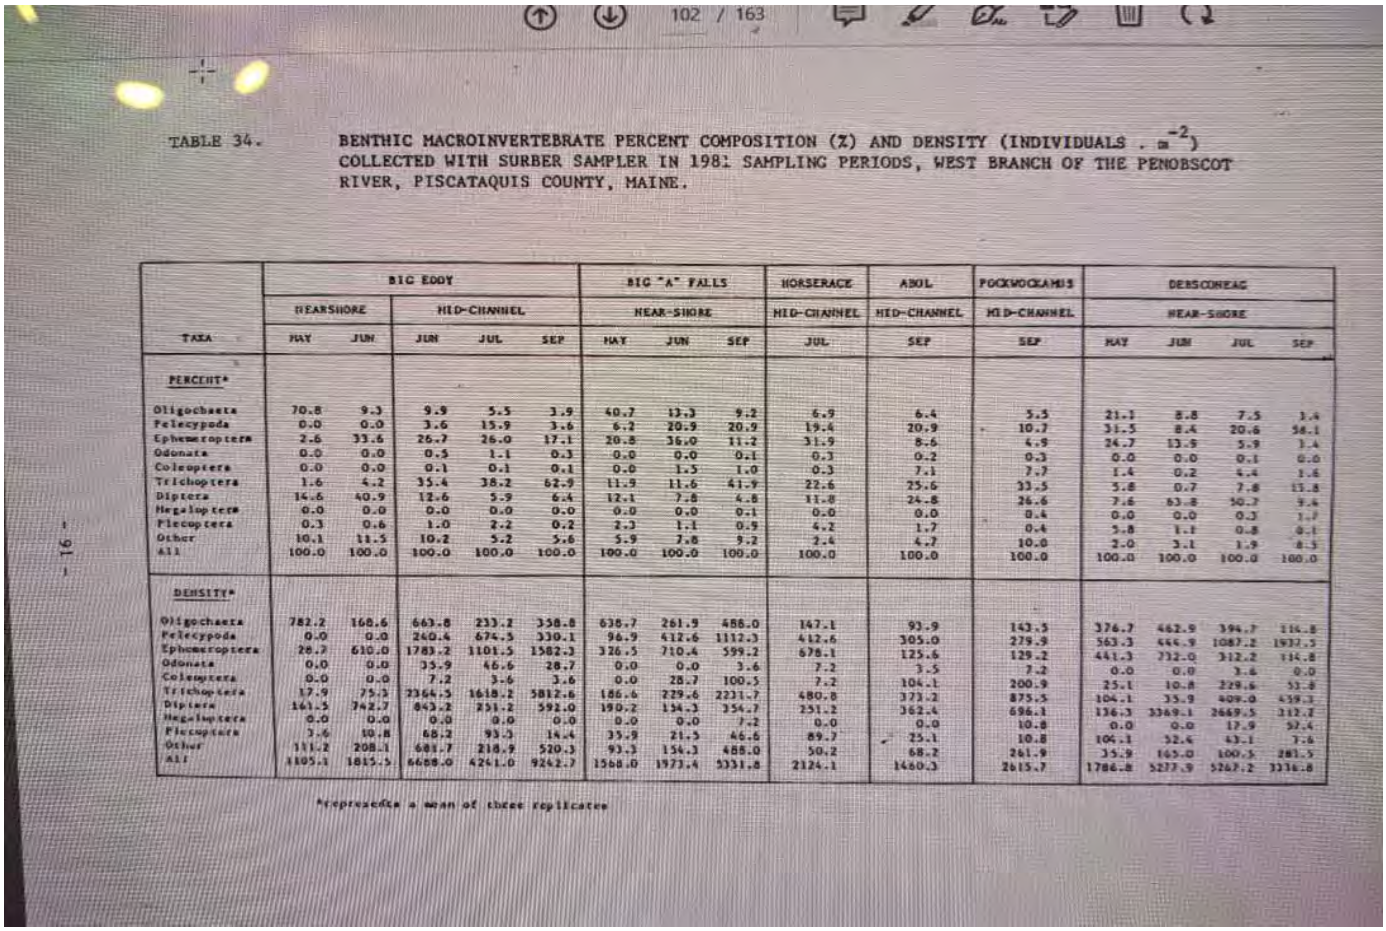


**Figure 9. Epilithon biomass and density of *Gammarus lacustris* in the permanently inundated and fluctuating flow littoral zones at 14 Mile Bar in 1992. Epilithon biomass values are means (SE) values *(n* = ;;i, 10) for samples collected usinl the same methods as for exposure experiments. *Gammarus lacustris* densities [mean (SE); *n* = 8] are from Hess samples (0·087m) collected at 14 Mile Bar**

**Macro invertrabrates are less mobile than fish and thus more vulnerable to peaking flows. The result is reduced abundance and the loss of velocity-sensitive species. Trotsky and Gregory (1974) described peaking and the resulting impact on River Kennebec aquatic communities below Wyman Dam. Moog (1993) describe the effects of peaking on macro invertrabrates and fish in Austrian rivers. Patterson, R. and K. Smokorowski (2011) studied macro-**

**inveterate drift on Magpie and Batchawana Rivers and summarized the available literature "Frequent and rapid fluctuations in flow can constitute a major factor contributing to the decrease in macroinvertebrate abundance and diversity in areas close to the dam (Cushman, 1985;Camargo and Voelz, 1998), with many studies observing drastic declines or elimination of macroinvertebrate communities in sections nearest a dam's discharge (Gore,1977; Boon, 1993; Growns and Growns, 2001; Vinson, 2001; House, 2002)." Lagarrigue et al (2002) who studied French Pyrenese rivers, stated "The flushing action of peaking flows caused a catastrophic drift, which was highest in autumn when the difference between natural and peak flows was greatest.** ***Overall drift density was higher below the hydro facility than in the control site above the facility where there was a clear diel pattern of drift, with low drift density during the day and high drift density at night, whereas no clear diel pattern was observed at below the hydro facility. Below the station, drift pattern appeared to be influenced most by hydropeaking".***

**Benthic macroinvertebrates are a standard used for biomonitoring purposes, and are known to demonstrate high sensitivity to flow alteration (Monk et al., 2006; Armanini et al., 2011), including clear responses to hydropeaking events, such as altered out-migration rates (drift) and shifts in density and biomass. Belmar et al., (2010) referenced the loss of taxa resulting from flow alteration.**

**A critical food source for salmon inhabiting the high gradient, ledge/boulder upper one and a half mile of the West Branch is hydropsychidae caddis (Trichoptera). During the 1980s macroinvertebrate sampling, Hydropsychidae caddis dominated upriver collections (see table below). Juvenile salmon prey on these net spinning caddis and caddis pupae and moths provide food to adult salmon during their late summer (August to mid-September) maintence period. Fuller and Fry (1991) report that diatoms are a favored food item among planktonic drift, growth increase with higher temperatures (20c) and that some species may be bivoltine (two annual generations). As Hydropsychidae prefer rocks, boulders and ledge for netting sites, they are vulnerable to sudden shifts in flow. Thus, present project operations are not only flushing caddis nets from marginal substrates but lake level management (or lack thereof) is reducing plankton availability as drift (food) through McKay Station.**

*represents a mean of three replicates

**Many/most of recent licenses for hydro-electric operations contain ramping prescription. Marty et al (2009) in a Magpie River study sponsored by Brookfield Renewal Energy (in effect, the licensee) reported ramping improved aquatic communities when compared to populations that were subject to unramped flows. Up and down ramping have been shown to modify the devasting effect of peaking. In its October 8, 2021 filing the Maine Department of Inland Fisheries and Wildlife commented on peaking operations and suggested ramping.**

**"Peaking power operations were not discussed in the WUP for the current license and were not anticipated. The literature is replete with examples of the detrimental impacts on the riverine fisheries and aquatic communities from rapid changes in flow. Flow changes of less than 25% per hour (ramping rate) can mitigate impacts from peaking power."**

**I agree, however given the high gradient of the area between McKay Station and the Big Eddy, some confirmation of an appropriate ramping rate is needed. With the dramatic change in project operations, by June, the adult salmon population is now concentrated in this reach and as demonstrated above, salmon prey items e.g., hydropsychid caddis, are vulnerable to dramatic flow change. Conservative (to the resources) measures are required.**

**A number of licenses/401 WQC filings provided ramping rates associated with their facilities. These prescriptions are quite variable both in rates and season;**

| Water | Ramping rate | | | | Target |
|---|---|---|---|---|---|
| | Spring | Summer | Winter | Fall | |
| Sultan River WA | 15 cm h-1 | 2.5 cm h-1 | 15 cm h-1 | | fry |
| Magpie River ONT | 25% from previous hour | | ---2 m3 s1 h1 | 1 m3 s1 h1 | fish & bugs |
| Snake River Idaho | Up or down… 50 cfs every half hour; from 0700 -1700 h only | | | | |
| Way Dam Wisc | 20% of current flow in 2 hour period, no more than 50% in 24 h | | | | |

**PacifiCorp Energy must limit Project-induced ramping of river stage as follows:**

| Project Reach | May 1 – September 30 | October 1- April 30 |
|---|---|---|
| Middle Fork Rogue River | Target of 1 inch per hour, not to exceed 2 inches per hour | Target of 2 inches per hour, not to exceed 3 inches per hour |
| Red Blanket Creek | Target of 1 inch per hour, not to exceed 2 inches per hour | Target of 2 inches per hour, not to exceed 3 inches per hour |
| North Fork bypassed reach | The target ramp rate is 100 CFS increase or decrease per 30 minutes, not to exceed 130 CFS per 30 minute interval. | |
| Rogue River below Powerhouse # 2 | The target ramp rate is 100 CFS increase or decrease per 30 minutes, not to exceed 130 CFS per 30 minute interval | |

Many other literature references to flow management and ramping exist. Peaking below Brookfield Renewable Energy's Brassua Lake Dam (FERC Project P2615) and the Moose River is prohibited from the end of "spring spill" to the end of June. Down ramping is a section 401 WQC, article 401 condition for Caucomgomoc Lake Dam, an impoundment of the Licensee's Storage Project (P-2634). The February 10, 2006 FERC order required flow reductions of no more than 50%/hour. While ramping rates vary, there are similar flow conditions that address extreme fluctuations in most recently licensed projects.

McKinney et al (2001) studied rainbow trout populations (stocked and wild fish) in the Colorado River below Glen Canyon Dam. Trout populations responded positively to an increased minimum flow and reduced daily flow fluctuation. Growth and abundance of wild trout improved following the 1991 modification of the flow regime. See below table.

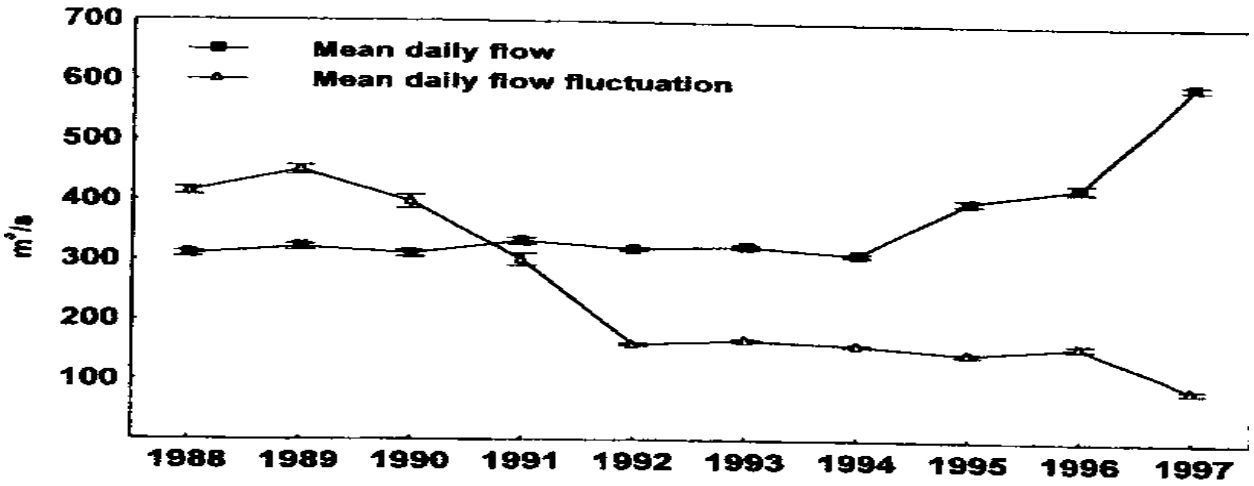

FIGURE 2.—Mean (±SE) annual daily flows and fluctuations from 1988 to 1997 of releases from Glen Canyon Dam, Colorado River.

The above paragraphs outline the complex relationship between salmon and aquatic communities in hydro peaking rivers. The Licensee included the 1992 FERC Ripogenus Project License application in the 2021 license application and FERC staff should use those data in comparison to 2022 study results. Many studies of the Ripogenus Impoundment and the West Branch below McKay Station are needed to define the present status of fish and aquatic

**communities. FERC approved studies should require an independent peer reviewed water management plan that includes an up and down ramping prescription protective of sensitive aquatic insects, namely hydropsychid caddis, and salmonids.**

**Thank you for the opportunity to comment.**

**Reference: Ripogenus Hydroelectric Project (P-2572-133)**

Significant evidence has been provided by numerous stakeholders that, contrary to GLHA's statements, there has been significant change to the project operations, ecosystems, and landowner development in the project area since their last license was approved. All of which speaks to the obvious fact, that the prior data filed decades ago needs to be updated to reflect today's current environment.

There has been much discussion about what new data may be required to evaluate GLHA's license application, but there has been no discussion about what ongoing data monitoring will be required during a new license period. The new license period could be as long as 50 years stretching out to 2075. There have been significant advances in scientific understanding of the changing global climate conditions since the last license was approved. Governments around the world and global scientific organizations recognize this fact and we in this GLHA project area sadly are seeing its effects today in our lakes and rivers and the ecosystem at large as has been stated by numerous comments.

The studies that this Commission will determine are necessary for it to make an informed decision will be based on the conditions that exist **today**. The problem is these conditions are predicted to change significantly in the near future, in fact within the proposed new license period for the GLHA application.

Given these facts, the Commission should not regulate using the same operational assumptions as was done during the 20th century as they are no longer appropriate. Admittedly, these are very complex issues but the climate is not static and, in fact, the changes to it are accelerating. Therefore, I respectfully ask the Commission to establish certain key criteria that will be monitored throughout the new license period in order to ensure if the conditions the Commission determined were necessary to be met in order to approve the new

license, continues to be met, and if not, adjust operational requirements as appropriate.

Respectfully,

Charles Paone

jimmy busque, MILLINOCKET, ME.
The attempt to require Brookfield to put fish ladders in all their dams on the Penobscot river in Maine would have a very negative impact on our native brook trout and world class salmon fisheries. These fish ladders will give Northern pike and alwives a clear path to the east and west branch of the Penobscot and destroy some of the last remaining native brook trout fisheries in the country and also the world famous salmon fisheries on the west branch. I urge FERC to not require Brookfield to build fish ladders that will destroy our fisheries.

**RE: Comments on Great Lakes Hydro America, LLC (GLHA) Proposed Study Plan for the Ripogenus Hydroelectric Project (FERC No. 2572) and Penobscot Mills Hydroelectric Project (FERC No. 2458)**

Dear Secretary Bose:

This responds to the November 22, 2021, Proposed Study Plan filed by Great Lakes Hydro America, LLC (GLHA) for the relicensing of the Ripogenus (P-2572) and Penobscot Mills Projects (P-2458) located on the West Branch of the Penobscot River in Maine. Our comments are attached and organized in such a manner to facilitate the Commission's review.

We appreciate your thorough consideration of the comments and look forward to working with GLHA and the Commission to develop an adequate Revised Study Plan for the Ripogenus and Penobscot Mills Projects. If you have any questions or need additional information, please contact Dan Kircheis at Dan.Kircheis@noaa.gov or 207-866-7320.

Sincerely,

Jennifer Anderson

**National Marine Fisheries Service's Comments on Great Lakes Hydro America, LLC November 22, 2021, Proposed Study Plan for the relicensing of the Ripogenus (P-2572) and Penobscot Mills Projects (P-2458)**

*The PSP Does Not Respond to NMFS or FERC's Additional Information Requests that are Necessary to Develop Study Plans for the Projects*

As stated in the Commission's March 2012 "Guide to Understanding and Applying the Integrated Licensing Process Study Criteria" (herein referred to as March 2012 Guide), Section 5.9(a) of the Commission's regulations provides parties the opportunity to request information to be gathered or to request studies. The March 2012 Guide states "The regulations do not differentiate between information requests and study requests. In practice, however, Commission staff treat additional information needs differently than study requests in that staff do not address the study criteria." The Commission's March 2012 Guide also states:

> "Additional information is information that is readily available and that can be provided to help clarify the proposal. Collecting this information should not rise to the level of conducting field work, performing a detailed analysis, or modeling to develop the data. This existing information should be relevant to the project proposal, is in the applicant's possession, or can be obtained with the exercise of due diligence. Staff often asks that this information be made available, preferably prior to scoping, but no later than issuance of the applicant's proposed study plan so as to effectively inform scoping and study plan development."

On October 8, 2021, we submitted our comments and study requests on GLHA's Notice of Intent to File License Application and Filing of Pre-Application Document for the Ripogenus and Penobscot Mills Projects. In our letter, we requested GLHA provide us additional information concerning operational data (daily minimum, maximum, and average flows) at all developments for the last ten years to determine impacts from operations to environmental resources including critical habitat designated for the Gulf of Maine distinct population segment of Atlantic salmon in the mainstem Penobscot River. These data are readily available to GLHA and necessary for project scoping. We specifically requested this data be submitted to us as part of the Proposed Study Plan.

On October 8, 2021, the Commission issued an Additional Information Request for detailed operations data needed to clarify how the projects are operated on a daily basis. Specifically, the Commission requested GLHA include as an appendix to the Proposed Study Plan, 10 years of operations data for each project, or each individual development, in the case of the Penobscot Mills Project, including: (1) Daily impoundment elevations; and (2) daily outflows (minimum, maximum, and average discharges). This request is consistent with the information requested by us, referenced in the paragraph above.

None of the data requested by us or the Commission were provided by GLHA in the November 22, 2021, PSP.

We note that the Commission revised their description of project operation at Millinocket, Dolby, and East Millinocket from "run-of-river" to "run-of-release" in the November 22, 2021, Scoping Document II. It appears that this change may have been informed by the Commission's receipt of additional guidance or information from GLHA; however, no such data or information has been provided to us. As noted in our October 2021 filing, this data is necessary to inform the development of proposed studies for the Ripogenus and Penobscot Mills Project. During the virtual PSP Meeting held on December 15-16, 2021, GLHA informed us they plan to treat our information request as a study request and that they intend to provide the requested information on April 22, 2023, as part of their proposed Historic Operations Data and Assessment Study. Given the need to fully understand current operational modes at the projects (i.e., run-of-river, run-of-release, or peaking), we also request GLHA provide us with hourly outflow data for McKay Station, North Twin, Dolby, Millinocket, and East Millinocket Projects for the last 10 years. Hourly data is needed for us to adequately scope the range of issues associated with this relicensing. This data, which is certainly readily available to GLHA and necessary to inform the development of study requests, should be provided to us and the Commission as soon as possible. Also, delaying the submission of these data for an additional fourteen months will irreparably impact the Commission's process plan and schedule that was outlined in Scoping Document II. Given that GLHA has ready access to this data, we request the data be provided to us within 14 days of this letter.

*The PSP Will Not Contribute to Developing an Adequate Environmental Report (Exhibit E) for the Projects*

In total, state and federal agencies and interested parties requested that GLHA conduct 35 studies to support the Commission's Integrated Licensing Process for the projects. GLHA's PSP outlines only eight new studies to support the relicensing of the Ripogenus and Penobscot Mills Project. At least two of the studies do not involve collecting any new data by GLHA. Instead, GLHA is proposing to support the relicensing of the Penobscot Mills and Ripogenus Projects by almost exclusively relying upon data collected by the previous owner of the projects during the prior relicensings which occurred over thirty years ago under a different mode of operation. It is our determination that if the studies are limited to those proposed in GLHA's PSP, significant gaps will exist and the licensee will not be able to prepare a complete and adequate Exhibit E to inform the Commission's development of their NEPA document. This would also hinder the ability of the resource agencies and the public to adequately evaluate the effects of the projects on resources of concern and impair the development of license conditions. Significant intervention from the Commission will be needed to develop a comprehensive PSP that remedies this situation.

As indicated in the March 2012 Guide , before the Commission can make an informed decision on a license application, it must obtain adequate information on the resources the project affects, such as soils, water quality, fish and wildlife, cultural, recreation, aesthetics, land use, and tribal resources. The Integrated Licensing Process was specifically designed to ensure that the information needs are known before a license application is filed through a Commission-approved study plan. Also, the Commission uses current conditions as its baseline for evaluating

project effects and alternatives. This consists of the environment as it exists *at the time of licensing* (emphasis added).

During the previous relicensing of the Ripogenus and Penobscot Mills Project, the former Licensee (Great Northern Paper Co. or GNP) conducted extensive studies and analysis to assess the effects of operating the projects on aquatic organisms and habitat within the West Branch of the Penobscot River. To develop their license applications for the Ripogenus and Penobscot Mills Projects, GNP collected environmental data from 1977 to 1990 prior to submitting the final licensing proposal to the Commission in December 1991. GNP studied the West Branch of the Penobscot River for thirteen years to document the baseline conditions of environmental resources within the various areas affected by the projects. GNP did this in the context of the previous mode of operation, to facilitate the Commission's preparation of the necessary NEPA analysis for the prior licensing action. We note that during that relicensing, baseline conditions were established to reflect GNP's 1991 Water Use Plan. GLHA summarized the previous relicensing studies in a letter to the Commission dated September 24, 2021. These data, however, cannot reliably be used to represent the current environmental conditions in the project areas because: 1) There is no information available in the record that indicates GLHA has operated the project pursuant to GNP's 1991 Water Use Plan since purchasing the projects in 2001; 2) GLHA indicated in the June 2021 PAD there are no plans to operate the projects in accordance with the 1991 Water Use Plan; 3) the previous relicensing did not attempt to assess the effects of operating the Ripogenus or Penobscot Mills Projects on aquatic resources in the mainstem Penobscot River and occurred prior to the designation of critical habitat for Atlantic salmon; and, 4) the closure of the Millinocket and East Millinocket Mills in 2008 have undoubtedly altered the environmental conditions of the West Branch of the Penobscot River. Therefore, given that the previous studies reflect a baseline related to a water use plan and operational scheme that has not been relevant since 2001, it is not reasonable to rely on those studies for this relicensing. The current environmental conditions within the project area are presently unknown and must be established as part of this relicensing in order for the Commission to adequately complete a NEPA analysis on the effects of the projects on the West Branch of the Penobscot River and mainstem Penobscot River.

*The PSP is Factually Flawed in Evaluating NMFS' Study Requests*

In our October 8, 2021, letter, we requested the following studies:

- A study to evaluate how the operations of the Penobscot Mills and Ripogenus Dam affects the hydrology of the West Branch and mainstem Penobscot River using an Indicators of Hydrologic Alteration Model;
- A study to evaluate project effects on river temperature in the West Branch and mainstem Penobscot River; and
- A study to evaluate future flow and water temperature scenarios.

The October 8, 2021, study requests for the Ripogenus and Penobscot Mills wholly conformed to the Commission's seven point criteria for submitting study requests as part of the Integrated

Licensing Process under 18 CFR 5.9(b). Nevertheless, GLHA did not adopt our requested studies based upon nonfactual and illogical reasoning which we respond to individually below.

I. Indicators of Hydrologic Alteration Model

We requested that GLHA conduct a study on the affected reaches of the West Branch of the Penobscot River to inform impoundment levels and operational management of dams, both individually and in the aggregate, that are protective of fish, water quality, riparian habitat, and other ecosystem functions. We requested that GLHA detail how their dams, impoundments, and operations currently modify hydrologic variables, including magnitude, timing, frequency, duration, and rate of change in West Branch of the Penobscot River down to the Mattaceunk Project so that FERC can evaluate how these hydrologic regime modifications impact sea-run fish, including Atlantic salmon, and their habitats. This information is necessary to inform the development of license conditions. We stated that the objective of the study is not to have FERC consider "pre-project" conditions in the analysis for this relicensing; rather, the objective of the study is to inform future license conditions that are protective of aquatic resources in the West Branch of the Penobscot River and areas downstream of the projects that are affected by project operations. The study would achieve this objective by contrasting current conditions with conditions that are protective of aquatic resources; this allows for identification of project operations that would be protective of aquatic resources.

To accomplish the study, we recommended GLHA utilize the Indicators of Hydrologic Alteration (IHA) and Range of Variability Approach (RVA) methods as described by Meridian 2004 and Richter et al. 1996, 1997. The IHA method provides a hydrologic analysis technique that considers the overall hydrological requirements of the system, rather than specific objectives such as a short list of species or geomorphic processes (Meridian 2004). In addition, the model defines a hydrologic regime that is more likely to maintain or restore the natural biotic composition, structure, and function of the river system (Meridian 2004). The RVA method was subsequently developed to provide a tool that establishes flow targets based on the results of IHA analysis and goals for meeting resource objectives (Meridian 2004).

In the PSP, GLHA did not adopt this study request. GLHA claims the study request did not conform to FERC's study criteria. We disagree and demonstrate below that we did conform with FERC's criteria. The Commission's March 2012 Guide provides a near exact example for establishing the nexus between operation of the Ripogenus and Penobscot Mills Project and Atlantic salmon critical habitat in the mainstem Penobscot River.

> "For example, say an entity requests a survey for a federally endangered fish species and its habitat downstream of an existing project that operates in a peaking mode; that is, the project generates during peak demand periods and stores water during off-peak periods such that there are fluctuations in water levels within the reservoir and downstream of the powerhouse. If one of the factors leading to the listing of the fish has been the loss of spawning habitat, the study proponent could easily demonstrate a nexus between the presence of the fish or its habitat downstream of the project and the project's effect on spawning habitat due to fluctuating flows from its peaking operation. If the study found the listed species within the affected reach but in low numbers compared to comparable unregulated reaches, the new license might include

measures to improve spawning habitat such as modifications in the timing and magnitude of releases or habitat improvements in the affected reach. If spawning habitat is a cumulatively affected resource in the basin, the requested project-specific information would also help staff conduct its cumulative effects analysis."

GLHA states in Volume 1 of the PAD, Section 1.6, that the impoundments and operations modify flows in the mainstem Penobscot River. Specifically, "The Project storage impoundments are managed on an annual cycle to dampen the variability and occasional extremes of seasonal precipitation and runoff through storage within the impoundments. This storage allows for continuous flows to downstream aquatic habitat and spawning areas within the West Branch and the mainstem of the Penobscot River during times of lower inflows to the system. In addition, the storage allows flows from the West Branch to be reduced during higher seasonal flow periods when the combined flows from the East and West Branches have the potential to adversely impact human life, property, and environmental resources downstream along the mainstem Penobscot River."

GLHA acknowledges that operation of the Penobscot Mills and Ripogenus Projects affects the mainstem of the Penobscot River. Project impoundments and flow management that affect flows in the mainstem may have direct effects on sea-run fish, including endangered Atlantic salmon; therefore there is a clear project nexus and a full analysis of project effects on flows in the mainstem should be conducted. As such, we disagree with GLHA's conclusion that our study request does not conform to the Commission's study criteria under the Integrated Licensing Process.

Below, we respond to several specific claims asserted by GLHA in the PSP pertaining to our requested IHA study.

In rejecting our study request, GLHA claims that conducting an IHA study on the West Branch or any other reach of a highly regulated river system such as the Penobscot River, is both inappropriate and unnecessary. GLHA also claims that an IHA model will not provide any useful information regarding the effects of Project operations on Atlantic salmon or other diadromous fish species. We disagree with both of these claims, as explained below.

<u>GLHA's Claim the IHA Study is Unnecessary</u>
Data collected during the past relicensing is not applicable to this relicensing since the mode of operation has changed from powering paper mills to maximizing electrical output to ISO New England. Furthermore, since GLHA has no plans to operate the projects in accordance with the 1991 Water Use Plan, the environmental baseline and GLHA's current mode of operating the projects must be evaluated as part of this licensing proceeding. Furthermore, this study will allow the Commission to evaluate alternative operations of the Ripogenus and Penobscot Mills Projects in their NEPA analysis.

GLHA also asserts our study request is not necessary because existing information is sufficient to answer the questions posed. GLHA argues the study is not necessary because river flows were evaluated at the Mattaceunk Project located on the mainstem Penobscot River approximately 13 kilometers downstream of the confluence of the West and East Branches of the Penobscot River. GLHA attempts to draw similarities between different projects that operate in different modes (i.e, run-of-river vs. run-of-release vs. peaking), to support the assertion that "existing information is sufficient." There is no data presently available that assesses how operation of the Ripogenus or

Penobscot Mills Projects impacts habitat for anadromous species including endangered Atlantic salmon in the mainstem Penobscot River. Data collected during this study will be used to fully evaluate existing operations (which presently remain unknown) compared to alternative modes of operating the projects for the protection of aquatic habitat and resources in the mainstem Penobscot River.

GLHA's Claim that the IHA Study is Inappropriate

Although the March 2012 Guide indicated that it is not necessary to demonstrate with "certainty" that a study will result in a license condition since it is premature at this stage in the process, we are fully confident that our requested IHA study will inform license conditions that will serve to protect Atlantic salmon and their critical habitat in the mainstem Penobscot River.

Last, the Commission has approved and/or required an IHA assessment as part of the relicensing of at least 10 hydroelectric projects undergoing relicenings include: Jackson (WA) (P-2157); McCloud-Pit (CA) (P-2106); Drum-Spaulding/Yuba-Bear (CA) P-2310, P-2266, P-2784; Merced (CA) (P-2179); Snohomish County PUD No.1 (WA) (P-14295); Bucks Creek (CA) (P-619); Skagit (WA) (P-553); Phoenix (CA) (P-1061). Therefore, it is reasonable to conclude that the Commission can consider IHA studies to be appropriate and necessary. As stated in the March 2012 Guide, "models are useful tools for conducting an analysis of effects and alternatives, and can help determine the scope of issues and corresponding analysis. Commission staff will consider any study requests that propose the use of operation models in accordance with the study criteria and will require their use as appropriate." Our study request proposes the use of operation models in accordance with the study criteria and it is our assessment that the use is appropriate here.

II. Project Effects on River Temperature in the West Branch

We requested a study to "Evaluate Project Effects on River Temperature in the West Branch and Mainstem of the Penobscot River." It is our assessment that because the West Branch drains 24 percent of the entire Penobscot Basin (NMFS, 2009) and approximately 57 percent of the river is impounded by dams (USACOE, 1990), the modified flows resulting from the impoundments and operations of Ripogenus and Penobscot Mills may also modify water temperatures that could affect survival of sea-run fish, including endangered Atlantic salmon and their critical habitat. However, there is no information on which to base an analysis of these effects or to inform recommendations or requirements for project operations that would mitigate these effects. In the PSP, GLHA did not adopt this study request. Rather, GLHA claims the study request constitutes "basic research" and/or is not likely to inform the development of license conditions.

GLHA states in Volume 1 of the PAD, Section 1.6, that the impoundments and operations of the Ripogenus and Penobscot Mills Projects are used to modify flows in the mainstem Penobscot River. The controlled releases at the projects is designed to "dampen the variability and occasional extremes of seasonal precipitation" in the West Branch and mainstem Penobscot River (Penobscot PAD Vol. 1). It is reasonable to conclude that these flow manipulations directly affect Atlantic salmon and their critical habitat in the mainstem Penobscot River.

Presently, there is no information on the effects of current operations of the Penobscot Mills and Ripogenus Projects on ambient river temperatures in the West Branch of the Penobscot River or

mainstem Penobscot River. This information is necessary to inform potential license requirements to minimize the effects of project operations on water temperature and to ensure appropriate operational measures and procedures are in place to afford necessary protection of sea-run fish and their ecosystems that may directly impact survival of Atlantic salmon and other diadromous fish.

In the PSP, GLHA did not adopt this study request. In the PSP, GLHA claims the study request constitutes basic research and/or is not likely to inform the development of license conditions. We disagree. Studies to evaluate river temperatures do not constitute basic research. Further, 18 CFR §5.9 specifically states that an Applicant's PAD must provide data concerning seasonal variation of existing water quality data including water temperature for any stream, lake, or reservoir that would be affected by the proposed project. Temperature studies are necessary to understand how the project and its operations affect water temperatures and inform measures the licensee can take to offset adverse impacts in order to protect aquatic resources. We have determined that there is no current data on project impacts to temperature in the West Branch and mainstem because the current conditions and project operations have changed substantially since the last relicensing, and any previous temperature data is no longer relevant to the current relicensing.

Changing environmental conditions:
Environmental conditions have changed substantially since the last relicensing; therefore, any water temperature data collected previously is not informative of current conditions or conditions anticipated during any new licenses. We call attention to the Maine's Climate Future report produced by leading experts from the University of Maine's Climate Change Institute (Fernandez et al. 2020). The 2020 update describes how Maine's average annual temperature has increased 3.2 degrees in the last 124 years with most of that warming having occurred since 1960. The report goes on to state that the Northeast is warming faster than any other region in the U.S. In Northern Maine (the area that includes the entire West Branch Penobscot), the average annual temperature has increased approximately 3.1 $^{o}$F since 1895, of which approximately 1.4 $^{o}$F of that warming has occurred over the last 30 years.

Change in operations:
As we call attention to in the IHA study request, the previous relicensing did not attempt to assess the effects of operating the Ripogenus or Penobscot Mills Projects on aquatic resources in the mainstem Penobscot River and, the closure of the Millinocket and East Millinocket Mills in 2008 have undoubtedly altered the environmental conditions of the West Branch of the Penobscot River. It is reasonable to expect that these factors impact how project operations affect temperature in the West Branch and mainstem Penobscot. Therefore, the current environmental conditions within the project area are presently unknown and must be established as part of this relicensing in order for the Commission to adequately complete a NEPA analysis on the effects of the projects on the West Branch of the Penobscot River and mainstem Penobscot River. This information is also necessary to inform ESA consultation and develop recommendations/requirements for any new license. It is well documented that changes in streamflow, including dam impoundments and flow management through dams, can significantly affect water temperatures due to changes in thermal capacity, with water temperature being

inversely related to discharge (e.g. Webb et al. 2003). The Commission could certainly order GLHA to operate the project's outflows and impoundments in a manner to minimize affects to steam temperatures including relocating intakes to withdraw deeper, cooler waters in the project impoundments.

Impacts to Aquatic Resources:
As we stated in our study request, water temperature is one of the most important environmental factors affecting all forms of aquatic life in rivers and streams (Annear et al. 2004). Temperature is especially important for Atlantic salmon given that they are poikilothermic (i.e., their body temperatures and metabolic processes are determined by temperature). Temperature can be a stimulant for salmon migration, spawning, and feeding (Elson 1969). Temperature can also significantly influence egg incubation success or failure, food requirements and digestive rates, growth and development rates, vulnerability to disease and predation, and may be responsible for direct mortality (Garside 1973; Spence et al. 1996; Peterson et al. 1977, Whalen et al. 1999).

Based on the information currently available to us, we expect that these projects exacerbate the impacts of climate change by causing additional warming of the West Branch and mainstem Penobscot River. The dampening of flow variability and the storage of water in the large reservoirs created by the Ripogenus, North Twin, and Millinocket Dams changes the hydraulic conditions in the river downstream of the project. As we indicate above, it is well documented that changes in streamflow, including dam impoundments and flow management through dams, can significantly affect water temperatures due to changes in thermal capacity, with water temperature being inversely related to discharge (e.g. Webb et al. 2003).

The combined effect of increased stream temperatures associated with these operations along with a warming climate can negatively affect the reproductive success of salmonids (e.g. Mantua et al. 2010).

In summary, the significant increases in the average annual temperature since the last relicensing and the understanding that impoundments and changes in stream flow can significantly impact water temperature provides the basis for evaluating the project effects on river temperatures in the West Branch and the mainstem and identifying management measures that the licensee can take to offset these impacts.

III. Future Flow and Water Temperature Study

GLHA states in Volume 1 of the PAD, Section 1.6, that the impoundments and operations are used to modify flows in the mainstem Penobscot River. It is reasonable to expect that these modified flows may exacerbate the effects of climate change. The operations of the Penobscot Mills Projects and Ripogenus Dam reduce the magnitude and frequency of flow variability throughout the Penobscot (GLHA 2021). Changes in streamflow, including dam impoundments and flow management through dams, significantly affect water temperatures due to changes in thermal capacity with water temperature being inversely related to discharge (Webb et al. 2003). The combined effect of a warming climate along with altered stream flows can negatively affect the reproductive success of salmonids (e.g. Mantua et al. 2010). An IHA analysis of how these

dams and their operations may exacerbate potential future climate conditions (e.g. extreme drought, flood events, extreme temperatures) and identification of mitigating measures that can be taken to offset these impacts, in conjunction with this temperature study request, is necessary to inform potential license requirements.

GLHA contends that the future flow and water temperature study request constitutes basic research and/or is not likely to inform the development of license conditions. We disagree. The licensee states that they already have the operational flexibility to accommodate annual and seasonal hydrologic variations. Yet they have not demonstrated if and how they are exercising this flexibility to ensure adequate protection of the natural resources affected by their projects. This is clearly articulated in the large number of comments on the PAD that describe extreme lake level changes in Ripogenus, and inconsistent, highly variable flows that has had adverse impacts on fisheries in the West Branch. To date, the licensee has been unwilling to provide the flow data necessary to demonstrate otherwise.

Future flow and temperature conditions are likely to change over the term of the next license as climate conditions continue to change. In order to protect aquatic communities in the Ripogenus and Penobscot Mills Project areas, the Commission will need to develop operational scenarios that are able to respond to these changing climate conditions, like those that resulted in extreme low lake levels in Ripogenus during the summer of 2021. The best available science states that the climate in Maine is warming and will continue to warm, and as a consequence, precipitation types, rates and duration will continue to change (Allen et al. 2021; Fernandez et al. 2020). Specifically, the 2021 *IPCC report on Climate Change* (Allen et al. 2021) projects that the Northeast U.S. will trend towards warmer and wetter, and the University of Maine's Climate Change Institute reports that Northern Maine's average annual temperature has increased by 3.1º F since 1895, and approximately 1.4 ºF over the last thirty years (Fernandez et al. 2020). The science is clear that the most plausible climate future will be one that is warmer, likely leading to continued changes in precipitation rate, intensity, and duration as well as snowpack and the timing of the spring snow melt. All of these factors impact the operations of these projects and their ability to adequately protect aquatic resources throughout the West Branch and mainstem Penobscot. Accordingly, the future flow and temperature study is necessary to obtain the information required to respond to likely future climate scenarios through the development of operational plans and procedures, in the form of license conditions, necessary to ensure protection of the natural resources throughout the Penobscot River.

# AMERICAN WHITEWATER AND APPALACHIAN MOUNTAIN CLUB COMMENTS IN RESPONSE TO PROPOSED STUDY PLAN FOR THE RIPOGENUS HYDROELECTRIC PROJECT (P- 2572) AND PENOBSCOT MILLS HYDROELECTRIC PROJECT (P-2458)

American Whitewater ("AW") and Appalachian Mountain Club ("AMC") submit the following Comments in response to the filing of the Proposed Study Plan for the Ripogenus Hydroelectric Project and Penobscot Mills Hydroelectric Project (FERC Project Nos. P-2572, P-2458) by Great Lakes Hydro America, LLC ("GLHA").

AW and AMC have long been involved with the FERC licensed hydropower projects in Maine, including hydropower projects located on the Penobscot, Kennebec, Rapid, and Magalloway rivers, and are party to settlement agreements that provide for whitewater boating opportunities that partially mitigate for project impacts. Our organizations participated in the initial scoping meeting and filed comments and study requests for these Ripogenus and Penobscot Mills projects. We file these comments to address the deficiencies in GLHA's Proposed Study Plan in relation to study requests by our organizations and other stakeholder in the FERC relicensing to adequately understand the aesthetic, ecological and recreational impacts of project operations in, below and in proximity to  the project boundary.. We request that the licensee consider these comments along with those filed by FERC, resource agencies, and other stakeholder groups in developing a Revised Study Plan that will provide information that will inform the environmental analysis of project effects on non-developmental resources.

## I. Comments on Scoping Document 2 (SD2)

The PSP was filed by the applicant nearly concurrent with the filing of SD2, issued by FERC. Understandably, the development of the PSP was not fully informed by SD2 due to the timing of these filings. At the December 15 and 16, 2021 PSP meeting, many stakeholders raised questions about the needed revisions in the study plan to reflect the updated scope of the NEPA analysis as provided for in SD2 with no commitments by the applicant to provide a RSP that reflects the

scope of SD2 and stakeholder comments. AW/AMC reiterate these comments in this filing, such that the PSP will not address significant project impacts as identified by stakeholders and as identified in SD2 unless it is significantly revised. SD2, in addition to the PAD and scoping comments of AW/AMC and other stakeholders, provides the applicant with a more thorough understanding of project related impacts that must be studied.

SD2, in sections 3.0 and 4.0, adds clarity to the scope of the studies needed to inform the NEPA analysis. Specific to the AW/AMC interests, SD2 includes a number of issues related to the ecology, fishery, and recreational uses and impacts of project operations on Millinocket Stream and on the West Branch below Stone Dam. These river reaches and the dewatered bypass reach below the Ripogenus project and upstream of McKay Station are of interest to AW/AMC for these reasons and others and our specific comments are included herein.

II, General Comments on Proposed Study Plan

In summary, the PSP fails to meaningfully respond to and incorporate a vast majority of resource impacts identified by stakeholders in their PAD and scoping comments. For perspective, 35 studies were requested by stakeholders, of which the PSP rejects 21 of these proposed studies. The applicant wrongly suggests that by proposing no changes to project operations that existing impacts of the projects on related resources does not need analysis. In addition to the PSP rejecting a wide range of appropriately requested studies, the applicant has also proposed to delay the filing of information that is needed to inform the stakeholder and agency understanding of how the projects are operated and what specific resource impacts are related to project operations. The filing of 10 years of daily operations data should be provided immediately, and not delayed until the RSP is developed. Though AW/AMC welcome the addition of a Historic Operations Data and Assessment Study in the PSP, the data that is held by the applicant to inform this study should be filed and made available as soon as possible.

With a short window of time to review and comment on the RSP, AW/AMC implore the applicant to meaningfully revisit and update and PSP to include a much wider range of studies requested by stakeholders and to expand the scope of those studies proposed in the PSP to incorporate the impacts identified in SD2 and in stakeholder PAD and scoping comments.

3.6 Study to Evaluate the Effects of Operating the Penobscot Mills and Ripogenus Dams on the Hydrology of the West Branch and Mainstem Penobscot River Using an Indicators of Hydrologic Alteration Model

The licensee declined NMFS study request that it perform a Indicators of Hydrologic Alteration Model to evaluate project effects on aquatic resources. Contrary to the licensee's claim that the study is seeking to recreate pre-project conditions, this study is seeking to evaluate the effects of the licensee's current operations on fish species. The purpose of relicensing is to evaluate the extent of project effects on environmental resources under current and alternative modes of operation. FERC's baseline assumes existing project facilities, not existing operations. Comparing current operations to natural flow conditions through an IHA model will allow FERC to determine adverse project effects on fish species resulting from project operations. This study would inform FERC's NEPA analysis and license conditions that address minimum and naturally available flows in bypassed reaches, peaking operations, and other factors affecting environmental quality. Brookfield's rejection of this study is based on the recurring theme that since it is proposing no operational changes, study of environmental impacts of current operations is unwarranted. To the contrary, this study is necessary to inform FERC's NEPA analysis. Additionally, the licensee asserts that the study is unnecessary because it performed a different study on another project 50 miles away from the Ripogenus Dam at the Mattaceunk Hydroelectric Project. While this study may provide some useful information that will assist in the completion of the proposed study, the Mattaceunk study only analyzes the effect of existing operations and does not compare current operations to more naturally occurring flows as would be analyzed under the proposed study.

3.8 Study to Evaluate Future Flow and Water Temperature Scenarios

The licensee rejects NMFS study request that the licensee evaluate the effects of project operations from climate change over the course of a 30-50 year operating license, arguing that the effects of climate change are too speculative for study. The licensee is keenly aware of these effects, however, as numerous projects that it operates were forced to curtail operations in 2021 due to what it characterized as "extreme hydrological conditions". In rejecting the study, the licensee relies on the CEQ regulations promulgated by the prior administration that largely ignore the impacts of a changing climate on the federal decision-making process. On October 7, 2021, CEQ issued a Notice of Proposed Rulemaking that is expected to restore prior CEQ regulations and require an assessment of the impact of climate change as part of the NEPA analysis. We expect that new regulations will be promulgated during this relicensing. Additionally, FERC has expanded consideration of climate change in recent guidance. As such,

FERC should require this information requested in this proposed study to complete its analysis of project impacts and the applicant should conduct this study as requested by NMFS.

3.19 Controlled Flow Whitewater Boating and Access Study

Notwithstanding FERC's issuance of SD2 making clear that whitewater boating below project diversion dams, bypassed reaches, and powerhouses will be evaluated as part of its NEPA review of project impacts, the licensee rejected AW/AMC study request that it conduct a whitewater boating study in four river reaches: 1) Ripogenus natural river channel bypassed reach; 2) Below McKay Station powerhouse; 3) Stone Dam natural river bypassed reach; and, 4) Millinocket Stream.

In rejecting this study request, the licensee argues that sufficient information is known about whitewater boating in these river reaches based on prior evaluations and there have been no subsequent changes that require study. While FERC may rely on relevant and adequate ***existing*** studies, those studies need to be available to the licensing participants and based on an accepted and robust methodology. Thus far, the licensee has been unable to produce any prior whitewater boating studies and has referenced other anecdotal information. To the extent that the licensee intends to rely on existing studies, it must produce them for analysis along with the supporting data.

In rejecting the AW/AMC whitewater boating study request, the licensee references a 1990 Whitewater Rafting and Boating Survey that was conducted as part of a larger survey regarding "Recreational Activities in the Ripogenus Project." We are unable to evaluate the adequacy of this study and the licensee has thus far been unable to locate this study data. At best, this study would only inform flow preferences of the reach below McKay Station and provides no information on the Upper Gorge, Stone Dam, and Millinocket Stream whitewater boating reaches that are directly affected by project operations. The standard for conducting new studies is not whether there have been significant changes since the last relicensing as the licensee contends, it is whether a study is necessary to provide FERC with information necessary to complete its environmental review in order to inform the development of future license conditions.

In the prior relicensing FERC issued an Additional Information Request on June 8, 1992 addressing deficiencies in the prior licensee License Application. The requests specifically addressed minimum flow required for navigation by canoe below the Stone Dam or so-called "Back Channel" (AIR #2), whitewater flows below McKay Station (AIR #17 and AIR #18), minimum flow required for navigation by canoe on Millinocket Stream (AIR #22),

On December 7, 1992, the prior licensee responded to FERC's AIR[1]. In its response to AIR #2, the licensee responded to the AIR by stating, unsurprisingly, that the natural river channel below Stone Dam was not navigable based on leakage flows from the dam. The licensee did not conduct any type of controlled flow study into the bypassed reach to identify minimum acceptable or optimal boating flows much less a study following the *Whittaker* methodology. The licensee's response to AIR #22 estimated that canoes could navigate Millinocket Stream at flows above 250 cfs. The licensee's methodology for reaching that conclusion was based solely on isolated interviews with three canoeists who previously boated the reach. The licensee did not include copies of its survey instruments or responses. Neither the licensee's response to AIR #2 nor its response to AIR #22 involved an analysis of river hydrology or a qualitative assessment of the reach under various flows. Additionally, there have been significant changes in whitewater boating craft and skill since the last relicensing such that any conclusions are no longer relevant to FERC's current NEPA review though they do demonstrate that these stream reaches have recreational values that are currently impacted by project operations. No response was provided to AIR #17 and AIR #18 in this filing and the licensee's methodology for evaluating minimum acceptable and optimal flows was not provided. The current flows of 1800 - 2300 cfs at McKay Station also falls below the 2400 cfs identified in the AIR. It does not appear that the licensee provided any information in its application on the recreation potential of the Upper Gorge above McKay Station.

The licensee further stated in the PSP meeting that, in lieu of a controlled flow whitewater boating study using FERC approved methodology, whitewater boating information at the project could be found on Google or YouTube. We are unaware of any relicensings where FERC has accepted Google and YouTube as an acceptable methodology for assessing project impacts on whitewater boating. In scores of other relicensings, FERC has required licensees to follow the methodology as described in Whittaker et al., in "*Flows and Recreation: A guide to studies for river professionals"* (2005)[2]. In our experience, Google and YouTube searches lack scientific rigor and will not provide FERC with sufficient information to complete its NEPA review of project impacts.

The licensee does not dispute that the project operations affect whitewater boating opportunity in and below its project boundaries. At Ripogenus, the project diverts flows from the West Branch of the Penobscot River into penstocks and powerhouses, reducing flows in the Upper Gorge below the Ripogenus Dam to a trickle. Information from whitewater boaters utilizing this reach during spill or when McKay station is offline clearly demonstrate that this reach is boatable and is a valuable whitewater boating resource. While we have established the boating potential of this reach, we are unable to precisely identify or reasonably estimate the minimum acceptable and optimal flow necessary for a quality whitewater boating experience. Additionally, the

[1] FERC Accession number 19921208-0260
[2] http://npshistory.com/publications/rtca/nri/flows-recreation.pdf *(Accessed 2/4/2022)*

licensee has provided no data that would permit FERC to understand the frequency with which these flows would be available under natural hydrologic conditions. The purpose of relicensing is to evaluate alternative modes of operation under a future FERC license. In the case of Ripogenus, those alternatives would necessarily include an evaluation of minimum flows and naturally variable flows being spilled into the Upper Gorge to benefit aquatic habitat and recreation use. Measuring the extent of the licensee's impact on these resources is necessary for FERC to complete its environmental review, and existing information is insufficient. Providing this information will inform the development of future license conditions. We would anticipate that a Level 3 whitewater boating study would be required for this reach because limited information is known.

For the whitewater reach below McKay Station, there is significant existing information known and a more limited study may be more appropriate for this reach. Under the *Whittaker* methodology, a Level 1 study would include collecting existing information from users through an online survey, focus groups, and/or user intercept surveys to collect information on user flow preferences. In addition, the licensee should also perform a desktop analysis of project operations to determine whether alternative modes of operation would improve the recreational user experience. In the prior relicensing, FERC requested that the licensee provide information on a range of whitewater flows in AIR #17 and AIR #18, noting flow preferences of 2400-3600 cfs by whitewater boating outfitters. The current flow levels of 1800-2300 cfs, depending on water year, fall below this level, and it is unclear whether the current flow regime is sufficient. Completing a Level 1 study of this reach should be sufficient to answer this question.

For the reach below Stone Dam, the licensee has provided no information whatsoever about the whitewater boating potential of this river reach. This reach is periodically boated when flows on the West Branch exceed the hydraulic capacity of the project or when the powerhouse is offline causing the licensee to restore flows to the river. At other times, this river reach is dewatered except for leakage and no flow information is publicly available. Anecdotal reports from whitewater boaters demonstrate that this river reach has sufficient gradient and structure to provide a high quality whitewater boating experience when sufficient flow is provided; however, there is insufficient information to identify minimum acceptable and optimal flow ranges. Clearly the licensee's project operations have a direct impact on the recreational boating opportunity in this river reach. Study is required in order to quantify project impacts on this recreational resource. We would anticipate that a Level 3 study would be appropriate for this river reach and would include a desktop analysis, single flow evaluation, and a multiple flow on-water study.

For Millinocket Stream, we would similarly anticipate the need for a Level 3 study. In response to AIR #22 in the prior relicensing, the licensee acknowledges that this river reach would provide valuable whitewater boating opportunities if sufficient flow were provided. Select interviews

with three local boaters provided limited information about target flow ranges and estimated that flows in excess of 250 cfs would be required to navigate the reach by canoe and that flows in excess of 600 cfs would provide a more challenging whitewater experience. These interviews were conducted prior to the development of modern playboats, stand up paddleboards (SUP), river runners, and creek boats that substantially expanded the range of crafts and skill levels of whitewater paddlers. No controlled flow study was performed in the last relicensing that would sufficiently evaluate the potential of this reach under a range of flow conditions. The licensee's operations directly impact recreational opportunity as project facilities dam and divert flows into the North Twin impoundment for project generation. Understanding the effects of project operations on recreation resources would require a desktop analysis of flows using data in possession of the licensee and not available to the public. Additional information on existing use should be collected as part of the Level 1 stage. In Level 2, the licensee should provide demonstration flows to identify a target range of flows to be evaluated during the Level 3 on-water flow evaluation. The licensee should assemble a working group with recreation stakeholder groups including AW/AMC for each study reach to be evaluated during the whitewater boating study.

The licensee's overall response to the whitewater boating study request essentially boils down to its belief that there are plenty of whitewater boating opportunities below McKay Station or on other rivers in the region so there is no need to study whether there are additional boating opportunities in the Upper Gorge, Stone Dam, or Millinocket Stream. This argument, however, goes to the appropriateness of additional PM&E measures rather than the need for study to determine the extent of project impacts and the value of the resource. Equally important is that not all whitewater boating experiences are the same and each river reach has unique characteristics. Simply put, a Class V whitewater run utilized by rafting outfitters and expert whitewater kayakers is not equivalent to a Class II/III river reach below the Stone Dam or Millinocket Stream used by less experienced boaters, open canoes, and paddleboards. Without study, the licensee assumes that these river reaches have no recreational value beyond what is available below McKay Station, an assumption not supported by any currently available data.

While the licensee asserts that whitewater boating locally and nationally is in decline, the data does not support this assertion. Due in part to new technology and equipment as well as the COVID pandemic, the public has rediscovered the value of outdoor recreation and use numbers show that outdoor recreation is at record level with these trends expected to continue. A survey of whitewater boating outfitters and industry confirms the growth trend in whitewater boating, and we share with the Commission the following:

- Rafting with *North Country on the Penobscot* was up 30 percent last year even without the benefit of Canadian rafting passengers that typically account for 35 percent of its business.

- Outdoor New England (ONE) in Franklin, New Hampshire reported sales increase in their whitewater department as follows: 2019 +51%, 2020 +68%, 2021 +102%. Owner Marty Parichand also reported selling kayaks to 40+ states in 2021.
- Zoar Outdoors in Charlemont, Massachusetts reported sales increase in their whitewater department as follows: 2019-2020 42% increase, 2020-2021 42% increase
- Jackson Kayak in Tennessee, total boats ordered: 3181 (2019), 3225 (2020), 4572 (2021). Colin Kemp Director of Sales at Jackson Kayak stated: "Never before in my time in paddle sports have I seen all top-end manufactures in the US sold out to capacity. We basically sold the whole year's production for the last two years in a matter of weeks. That is a fraction of the time it used to take to book 80% capacity. Unlike some brands, we pushed harder on WW because it is our heart and soul, and with a combination of some really well-received designs like the Antix and new RS I could likely sell at least double what was booked if I had extra oven capacity or molds."
- Pyranha Kayaks, Tennessee: 2017 +3%, 2018 + 3%, 2019 + 3%, 2020 + 30%, 2021 + 71%, 2022 orders + 70%
- Mountain Man Outdoor Supply Company Old Forge, NY: Total sales. 2019 $2.1 million, 2021 $3.2 million dollars
- Astral PFD sales were at an all time high in 2021 and products have been continually sold out.
- Northwest River Supply (NRS) in Idaho reports that the number of whitewater kayaking participants in the United States is trending upward, not downward and is currently holding steady at about 2.6 million, up from about 1.7 million in 2011. That makes for 53% growth in participation over 10 years based on national trends.

3.20 Aesthetic Resources Study

The licensee declined AW/AMC study request that it evaluate project effects on aesthetics, both in the river corridor and on lands occupied by project works. In order to develop the best adapted plan for the river, FERC is required under the Electric Consumers Protection Act to give equal consideration to non-developmental resources including aesthetics. The PSP does not identify any existing studies or data that would allow FERC to evaluate project impacts on aesthetic resources.

The PSP mischaracterizes the AW/AMC study request in that its response is limited to the request to identify light and sound impacts. The study also asks the licensee to evaluate the following goals:

> (b) Determine if the projects have an adverse effect on a scenic vista, riverscape, or other noteworthy natural feature;

(c) Determine if the project degrades the existing character or quality of public views of the site and its surroundings;

Accordingly, this study will also involve an assessment of the aesthetic impacts of project operations on the Upper Gorge, Stone Dam, and Millinocket Stream locations at key observation points. To clarify and supplement our request, we would propose that the licensee follow the methodology described in Whittaker et al., "*Flows and Recreation: A guide to studies for river professionals"* (2005) to evaluate the adverse aesthetic impacts of the project on the natural landscape including the natural river reaches in the Upper Gorge, Stone Dam, and Millinocket Stream reaches. This evaluation should include the identification of key observation points where the public can view dams, geologic features such as Grand Falls, as well as other project works where a team consisting of stakeholders can evaluate the effect of flows and facilities on the aesthetic quality of the project and project works. Based on evaluation forms, the licensee should prepare a study report assessing project impacts.

While the licensee argues that an aesthetic assessment lacks a nexus to the project, project operations have an undeniable effect on the natural landscape. The licensee acknowledges that the Upper Gorge Trail is utilized by the public. Project operations divert flows from the Upper Gorge leaving only a fraction of the natural flows in this river reach. A study is needed to assess the extent to which project operations impact the public's use and enjoyment of this and other areas in the project boundary.

In arguing that the study request lacks a nexus to project effect, the licensee relies on the *Centralia* decision (*City of Centralia v FERC*, 213 F.3d 742, 749 (D.C. Cir., 2000)) to argue that the study is an attempt to search for a problem where there is no evidence that problem exists. The licensee's reliance on Centralia is misplaced. That case concerned a post-license study of the need for a tailrace barrier net where there was substantial evidence in the record that the barrier net was unneeded. There the court found that the project effects of the discharge on fish were entirely speculative. Similarly, in *City of Jackson, Ohio*, 105 F.E.R.C. ¶61,136 n.9 (2003), a FERC decision on which the licensee relies, likewise involved a post-license study to assess whether the project was having an adverse effect on fisheries resources. This decision is inapplicable to circumstances such as are present on the West Branch of the Penobscot where the effect of the project on a protected resource is clear and the study is designed to evaluate the extent of that impact so that FERC can complete its NEPA review based on its scoping document. *FPL Energy Maine Hydro, LLC*, 95 F.E.R.C. ¶61,106 n.15 (2001) and in *Allegheny Energy Supply Company, LLC*, 109 F.E.R.C. ¶61,028, 61,117 (2004), also cited by the licensee, likewise involved the need for a license condition requiring a post-license study of project effects on fish. Each of these cases are inappropriate.

The licensee endeavors to extend the holding in *Centralia* and subsequent FERC decisions citing that case to argue against requiring studies *during* the pre application phase of the Integrated Licensing Process (ILP) to limit the information available to FERC for its NEPA analysis. FERC's nexus requirement in its study criteria was not intended to create a barrier to study of project effects on resources that is within FERC's power to address in a license condition. In effect, the licensee's circular logic would require prior study in order to justify the need for a study while prior study makes the need for a study unnecessary. To meet FERC's nexus criteria, a proposed study need only show that the project has a direct or indirect effect on a non-developmental resource that will be evaluated by FERC as part of its environmental assessment. By this flawed logic, an aesthetic study would never be justified and a license condition requiring aesthetic mitigation would be deemed arbitrary and capricious because it lacked study. This Catch-22 scenario was certainly not what Congress intended when the Electric Consumers Protection Act amended the Federal Power Act to require that FERC "shall give equal consideration to the purposes of energy conservation, the protection, mitigation of damage to, and enhancement of, fish and wildlife (including related spawning grounds and habitat), the protection of recreational opportunities, and the preservation of other aspects of environmental quality." 16 U.S.C. § 797(e)

3.21 Socioeconomics Study

The licensee rejects the request by the Penobscot Indian Nation to conduct a study analyzing the current socioeconomic environment and future trends including employment and recreation economy in the project area. The licensee devotes the bulk of its Pre-application Document to arguing that the project should be relicensed under current license conditions because the project is not proposing any change to current operations and in the last relicensing FERC appropriately balanced resource needs. Pivotal to FERC's balance was its socioeconomic analysis of the impact of mitigation measures on economics and employment, namely the Great Northern Paper Mill in Millinocket. The Ripogenus and Penobscot Mill projects produced approximately 108 MW of power for the Great Northern mill. Due to the impact on power generation that would result from requiring the licensee to restore flows to the dewatered 4.5-mile section of the West Branch below the Stone Dam, FERC did not require any flow restoration to the so-called "Back Channel", eliminating recreation opportunity and continuing the destruction of aquatic habitat. FERC justified its decision based on reasoning that the loss of power would affect the competitiveness of the mill and result in lost jobs.

Notwithstanding FERC's decision to sacrifice environmental quality to the hope of protecting the paper mill from economic harm, the Mill closed in 2008. To the extent that the licensee continues to argue that FERC's 1996 license appropriately balanced developmental and non-power resources, that determination was based on the socioeconomics of the region at the time of relicensing. Today, those socioeconomic conditions are different in a region that relies on the

outdoor recreation economy rather than the paper mill for its economic well being. In rejecting the proposed study, Brookfield cannot argue that the prior relicensing appropriately balanced resources as conditions have dramatically changed since the last relicensing. By conducting the requested socioeconomic study, FERC will be better able to determine the appropriate balance based on current socioeconomic conditions.

Recreation Study Plan

2.0 Goals & Objectives

The licensee's proposed Recreation Study Plan fails to adequately address any of the goals identified by AW/AMC in its study request. The licensee seeks to limit the scope of its study plan to an assessment of only those sites identified as project approved recreation sites under its current license. Though SD2 indicates that FERC will include an assessment of the whitewater opportunities below Stone Dam and on Millinocket Stream, these areas would not be included in the applicant's recreation assessment as proposed. AW/AMC reiterate our request to more thoroughly conduct the recreation study to include the following components:

1. Obtain information about the condition of existing formal and informal recreation facilities and access to lands and waters from the top of the Ripogenus impoundment to the bottom of the East Millinocket tailrace including Millinocket Stream, project storage areas, and bypassed reaches; and existing recreation use, and demand at the project and non-project locations in this area;

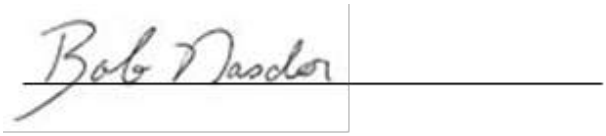
2. Evaluate the adequacy of existing access to areas in and adjacent to project lands including impoundments and bypassed reaches in the project boundaries and on lands from the top of the Ripogenus impoundment to the bottom of the East Millinocket tailrace including Millinocket Stream, project storage areas, and bypassed reaches, including formal and informal access areas that are utilized for boating, angling, hiking, and other recreational use;

3. Conduct an assessment of the need to enhance recreation opportunities and access from the top of the Ripogenus impoundment to the bottom of the East Millinocket tailrace including Millinocket Stream, project storage areas, and bypassed reaches;

4. Quantify and map the relationship between reservoir surface area and reservoir levels, and how those reservoir elevations relate to recreation; and,

6. Inform the development of a Recreation Management Plan for the implementation of any enhancement measures and long-term monitoring of

recreation demand and adequacy of project and non-project facilities over the term of new licenses.



For both the Ripogenus and Penobscot Mills projects, the applicant proposes a Recreation Facility and Inventory Assessment study. Considering the complexities of the projects, impacts of the projects on more than 60 miles of the West Branch of the Penobscot River and its tributaries, as well as the nationally significant recreation resources in and adjacent to the project boundaries impacted by the projects, the scope of the applicant's proposed Recreation Facility Inventory and Condition Assessment is inadequate and must be significantly expanded.

In order to adequately assess project impacts on recreation resources, the licensee needs to evaluate both formal and informal recreational sites from the top of the Ripogenus impoundment to the bottom of the Penobscot Mills developments rather than limiting its assessment to only FERC-approved recreation sites in the project boundary as proposed in its study. These sites should include the Ripogenus Gorge, Stone Dam, and Millinocket Stream reaches as well as the reach between the Ripogenus and Penobscot Mills boundaries including all reservoirs and riverine reaches. Additionally, the study should include user intercept surveys at both formal and informal recreation sites as well as internet-based surveys, targeted interviews, and focus groups as appropriate.

Conclusion

American Whitewater and Appalachian Mountain Club respectively request that the Licensee revise its Proposed Study Plan to address these comments and concerns in order to provide FERC with sufficient information to conduct its NEPA analysis of project impacts.

**RE: Comments on the Proposed Study Plans for Ripogenus Hydroelectric Project (FERC No. 2572) and Penobscot Mills Hydroelectric Project (FERC No. 2458) from the Caribou and Chesuncook Lake Camp Owners Association and the Chesuncook Dam Camp Owners Association.**

Dear Secretary Bose:

I am submitting these comments on the Proposed Study Plan (PSP) for the Ripogenus Project (P-2572) and the Penobscot Mills Project (P-2458) filed for Great Lakes Hydro America, LLC by Brookfield Renewable ("Brookfield") on behalf of the members of the Caribou and Chesuncook Lake Camp Owners Association and the Chesuncook Dam Camp Owners Association.

The two Associations represent over fifty camp owners with a significant and substantial interest in the relicensing of these projects. We have a deep love for and knowledge of, Caribou, Chesuncook, and Ripogenus Lakes, and have a large financial commitment to our properties. Many of our members have long multi-generational histories on the lakes and know them well before and after the current operator and applicant. It is our observation that Brookfield Renewable is operating Ripogenus Dam vastly differently than it was operated for its previous eighty-year history and now believe that numerous studies disregarded by the applicant are necessary for the health of the lakes as well as the recreational use of the lakes.

The 10 years of Operational Data requested by nearly all stakeholders is vital to the proceedings. Operational Data does not require a "study," as proposed by GLHA, it is simply providing data the licensee has. Data that will reveal the vast differences between operations 30 years ago and operations today. In the past application then dam operator, Great Northern Paper (GNP) stated "Since 1972 the maximum draw-down during the summer recreation period (between Memorial Day and Labor Day) has been 15.25 feet; the average has been 3.5 feet." Current operational data would clearly show the vast differences in operation. Operations that have profound impact on the wildlife and the entire ecology of the region, as well as significantly impacting property owners and recreational users of the lakes, rivers and project lands. This data is necessary to understanding and analyzing options in the new project operations.

Although GLHA proposes no modifications to current operations, and minimizes the need for numerous study requests, significant changes are necessary as the dam is operating vastly differently than it was 30 years ago and the socio/economic realities of the region have dramatically changed. Thirty years ago, energy from the dam was used to power a mill that was one of the largest employers in the region and even the state. This economic concern was the

driving force behind the UAA conceived at the time. A UAA that would not be issued if sought at this time, and is in dire need of reevaluation. The employer is now gone, tourism is a major economic factor in the region, and the power from the dam is used for profit. This profit cannot come at the expense of the lakes and river, the animals who live on/in it, recreational users of the area, and the property owners surrounding the project area.

In order to properly analyze the impact of the different operating procedures requested studies are needed. At the Proposed Study Plan (PSP) meeting GLHA presented, in a very polished manner, how well the operations are working and why the studies from 30+ years ago are still valid. Unfortunately, their presentation lacked substance about the lake and did not address the current realities. The lake-level and project operations are clearly different and it is absurd, insulting and untrue to claim differently. Operational data will prove this. We do not claim to be scientists, but many of us spend a large portion of the year on the lake and we can provide relevant, anecdotal data to support the requested studies.

The Freshwater Mussel study requested by the USFWS is an example of a necessary study that needs current data to inform decisions. Dead mussels, including potentially endangered species, litter the shoreline on the dramatically expanded littoral zone as a result of lake drawdowns much greater than claimed by GLHA. The remnant mussel shells leave a feast for gulls. Similarly, the Common Loon Management Plan Assessment and the Common Loon Productivity Assessment are studies GLHA discarded with claims about the success of the current management plan, which has not been updated in 10+ years. Evidence from numerous locations on the shoreline and lake reveal loon platforms high and dry, seemingly ineffective and apparently not maintained for many years. If project operations, and hence water levels, are dramatically different than in the past logic indicates the resulting impact will also be different.

The impact on camp owners and other recreational users has also been profound, necessitating a Recreation study. Camp owners on Caribou and Ripogenus lakes are unable to access Chesuncook Lake at low water, inhibiting their ability to fish, boat and recreate on all impoundment waterways. Many camp owners are unable to get water from the lake without extensive water systems or carrying large buckets of water over rocky shores. Campers and visitors to the area must do the same in mid to late summer as many campsites are long distances from the water. Docks and moorings quickly become unusable with constant drawdowns. Boats parked at the water’s edge must be moved every couple days to prevent them from being left high and dry. Access to lakes via the Chesuncook and Caribou Lakes boat landings also inhibits recreational access. The boat landings have become unusable during the recreational season for the past two summers. Even at the smaller drawdowns of early spring the boat landings are mere rocky paths to the water. In 1990, the Maine Department of Conservation stated “the limited development in the project area; the extensive, high-quality natural resources; the existing recreational facilities; and the amount of public use of the river make the Ripogenus Project area one of the most important recreational areas in Maine.” This highly valued area deserves studies to determine operational impact. GLHA has included a modified version of a Recreational study. It is vital this study includes camp owners as well as other summer and winter recreationists.

An Aesthetic study, not adopted by GLHA, is necessary to analyze the impact of severe lake drawdowns on the aesthetics of one of the greatest recreation areas in the country. As numerous pictures reveal, the aesthetic quality of the area is greatly diminished with unlimited lake drawdowns. Large rocks become exposed and walking is nearly impossible. As one visitor stated, the area becomes a moonscape.

We greatly appreciate how thoroughly the Commission identified stakeholder concerns and correspondingly modified the Scoping Document 2 (SD2) and the commitment to addressing listed environmental issues in the NEPA document. Unfortunately, GLHA's study plans are inadequate to meet the expectations of the SD 2. Essential studies are necessary to ensure all components of the SD 2 are met. We fully support all federal, state and NGO study requests. Additionally, we recognize the rapidly changing climate may necessitate future modeling, and a fluid, flexible permit that responds to changing climate realities. We ask the Commission to ensure **current** and relevant data is collected that will give us all the necessary information to mold a new, balanced permit that addresses the needs of the operator, the fish and wildlife, the lake and river ecology, and the people who so greatly value this unique and precious resource.

Respectfully,

Bill Houston
Spokesperson
Caribou and Chesuncook Lake Camp Owners Association and Chesuncook Dam Camp Owners Association

Michael J Smith, Millinocket, ME.
To whom it may concern:

I am a resident of Millinocket, ME and an avid user of the various reaches within the West Branch watershed. I am writing to share my enthusiastic support for flow studies that will help evaluate recreational opportunities and the ecological well-being of the Ripogenus Dryway, the West Branch below Stone Dam, and Millinocket Stream. These waterways are of profound importance to our local communities and the future of our region.

I also work with several community organizations within the Katahdin Region that rely on the West Branch and Millinocket Stream for recreational and educational programming. Millinocket Stream, in particular, with its proximity to residential neighborhoods, community green spaces, trails, local businesses, and community resources, is of profound importance to those of us that live here. Flow studies here and on the other reaches in question are critical in helping us understand how to best manage these waterways for future generations.

Thank you for your time and consideration.

Best,
Mike Smith

RE: Penobscot Mills (P-2458-247) and Ripogenus (P- 2572-133) Proposed Study Plan

Dear Secretary Bose,

I have reviewed the Proposed Study Plan (PSP) for the Ripogenus Hydroelectric Project (FERC NO. 2572) and the Penobscot Mills Hydroelectric Project (FERC NO. 2458), drafted by Great Lakes Hydro America, LLC (licensee) on November 22, 2021. I have also reviewed the comments submitted by the Penobscot Indian Nation (PIN) on February 18, 2022 and October 12, 2021. I support the PIN's request for an updated socio-economic study.

The current state of the economy in Maine and in the specific region where the dams reside has changed much since the previous licensing event. In addition, our understanding of how marginalized groups (e.g., Black, indigenous, and other people of color, rural, low-income) have borne proportionally more costs of energy production compared to other groups has increased. The literature and practical decision-making related to energy equity and justice have changed drastically in the last decade alone. As a researcher and educator who focuses her work on understanding trade-offs in energy decisions that have multiple positive and negative economic, environmental, and social implications, I recommend a new socio-economic study be conducted for the dams involved in these two relicensing events.

I recommend at a minimum the study replicate what was done in the previous relicensing but with updated input data and calculations. However, a more engaged study would more accurately capture the socio-economic state of being during this time period and lead to more robust results for all parties involved. I recommend the study start with a working group that engages all members of the communities affected (in positive, negative, and neutral ways) by the dams in multiple dialogues to identify the socio-economic indicators that are important to their livelihoods and lifeways. I recommend experts in socio-economic research (i.e., myself, my colleagues at the University of Maine, and/or others) be engaged in the working group to help identify appropriate methodologies for measuring the indicators identified by the working group.

Once indicators are identified, data collected, and the appropriate methodologies implemented for each indicator, a quantitative integrative tool like social benefit cost analysis or multi-criteria decision analysis can be used to identify a total value and/or ranking for various decision points using the new socio-economic data and results. This type of integrative analysis could be conducted in close collaboration with the broader NEPA analysis.

In this time of transition from fossil fuels to renewable energy and enhanced focus on energy equity and justice, it is advisable in such a crucial decision juncture as relicensing to take the time to make sure we are working with the most up-dated data, analysis, and options in the broader decision space.

Sincerely,

Dr. Sharon Klein

FERC's issuance of SD2 making clear that whitewater boating below project diversion dams, bypassed reaches, and powerhouses will be evaluated as part of its NEPA review of project impacts, the licensee rejected AW/AMC study request that it conduct a whitewater boating study in four river reaches: 1) Ripogenus natural river channel bypassed reach; 2) Below McKay Station powerhouse; 3) Stone Dam natural river bypassed reach; and, 4) Millinocket Stream. In rejecting this study request, the licensee argues that sufficient information is known about whitewater boating in these river reaches based on prior evaluations and there have been no subsequent changes that require study. While FERC may rely on relevant and adequate existingstudies, those studies need to be available to the licensing participants and based on an accepted and robust methodology. Thus far, the licensee has been unable to produce any prior whitewater boating studies and has referenced other anecdotal information. To the extent that the licensee intends to rely on existing studies, it must produce them for analysis along with the supportin data.

In rejecting the AW/AMC whitewater boating study request, the licensee references a 1990 Whitewater Rafting and Boating Survey that was conducted as part of a larger survey regarding "Recreational Activities in the Ripogenus Project." We are unable to evaluate the adequacy of this study and the licensee has thus far been unable to locate this study data. At best, this study would only inform flow preferences of the reach below McKay Station and provides no information on the Upper Gorge, Stone Dam, and Millinocket Stream whitewater boating reaches that are directly affected by project operations. The standard for conducting new studies is not whether there have been significant changes since the last relicensing as the licensee contends, it is whether a study is necessary to provide FERC with information necessary to complete its environmental review in order to inform the development of future license conditions.

In the prior relicensing FERC issued an Additional Information Request on June 8, 1992 addressing deficiencies in the prior licensee License Application. The requests specifically addressed minimum flow required for navigation by canoe below the Stone Dam or so-called "Back Channel" (AIR #2), whitewater flows below McKay Station (AIR #17 and AIR #18), minimum flow required for navigation by canoe on Millinocket Stream (AIR #22), On December 7, 1992, the prior licensee responded to FERC's AIR1. In its response to AIR #2, the licensee responded to the AIR by stating, unsurprisingly, that the natural river channel below Stone Dam was not navigable based on leakage flows from the dam. The licensee did not conduct any type of controlled flow study into the bypassed reach to identify minimum acceptable or optimal boating flows much less a study following the Whittaker methodology.

The licensee's response to AIR #22 estimated that canoes could navigate Millinocket Stream at flows above 250 cfs. The licensee's methodology for reaching that conclusion was based solely on isolated interviews with three canoeists who previously boated the reach. The licensee did not include copies of its survey instruments or responses. Neither the licensee's response to AIR #2 nor its response to AIR #22 involved an analysis of river hydrology or a qualitative

assessment of the reach under various flows. Additionally, there have been significant changes in whitewater boating craft and skill since the last relicensing such that any conclusions are no longer relevant to FERC's current NEPA review though they do demonstrate that these stream reaches have recreational values that are currently impacted by project operations. No response was provided to AIR #17 and AIR #18 in this filing and the licensee's methodology for evaluating minimum acceptable and optimal flows was not provided. The current flows of 1800 - 2300 cfs at McKay Station also falls below the 2400 cfs identified in the AIR. It does not appear that the licensee provided any information in its application on the recreation potential of the Upper Gorge above McKay Station.

The licensee further stated in the PSP meeting that, in lieu of a controlled flow whitewater boating study using FERC approved methodology, whitewater boating information at the project could be found on Google or YouTube. We are unaware of any relicensings where FERC has accepted Google and YouTube as an acceptable methodology for assessing project impacts on whitewater boating. In scores of other relicensings, FERC has required licensees to follow the methodology as described in Whittaker et al., in "Flows and Recreation: A guide to studies for river professionals" (2005)2. In our experience, Google and YouTube searches lack scientific rigor and will not provide FERC with sufficient information to complete its NEPA review of project impacts.

The licensee does not dispute that the project operations affect whitewater boating opportunity in and below its project boundaries. At Ripogenus, the project diverts flows from the West Branch of the Penobscot River into penstocks and powerhouses, reducing flows in the Upper Gorge below the Ripogenus Dam to a trickle. Information from whitewater boaters utilizing this reach during spill or when McKay station is offline clearly demonstrate that this reach is boatable and is a valuable whitewater boating resource. While we have established the boating potential of this reach, we are unable to precisely identify or reasonably estimate the minimum acceptable and optimal flow necessary for a quality whitewater boating experience.

Christopher Howe, kingfield, ME.
My name is Christopher Howe I am the river manager for North Country Rivers on the Penobscot. I have worked on the Penobscot since 2009
and the last 2 seasons have been the busiest I have ever seen. Pre-Pandemic, we had an average 4-5 full time staff, and this year I have
8 full time staff lined up to work in 2022. The future of whitewater is very bright in America and the value of this sport to youth and adults
alike cannot be over-stated.

Millinocket has seen hard times since Great Northern shuttered the mill in the early 2000s. Tourism has played a huge role in helping
fill the economic void that has plagued the town since the mill shut down. Millinocket and the Katahdin Region would only benefit from
expanding high quality whitewater recreational opportunities on nearby rivers.

Brookfield and Great Lakes Hydro rejected requests for flow studies to properly assess and catalog whitewater boating opportunities below
Millinocket Lake Dam, Ripogenus Dam, and Stone Dam. This re-licensing project has an unprecedented opportunity to highlight the quality whitewater affected by GLH projects, during a time of exponential growth in whitewater paddle sports. For these resources and opportunities to go unstudied
for another 35 years would be an extreme disservice to Millinocket, the Katahdin Region, and its future potential. If recreational flows
were given in these river reaches, in addition to what we already have below McKay Station, an individual could progress from a complete novice to an expert whitewater
paddler with only having to drive 30 minutes from Millinocket.

There is no official data documenting whitewater boating between Ripogenus Dam and McKay Hydro station. GLH and Brookfield egregiously state that this is a unnavigable
and dangerous stretch of river, while gigabits of video and photo content exists on the internet proving that it is the opposite. A weekend of scheduled releases on this stretch of river could be the center piece of a paddling festival that could draw hundreds of paddlers to our remote corner of Maine.

There are also no official data documenting paddling opportunities between Millinocket Lake Dam and the Town of Millinocket. This stretch of river is perhaps in my view the most important section of river under review in this process. Millinocket Stream has huge potential to act as a gateway into a positive and healthy hobby for youth and residents of Millinocket. Currently local schools and youth programs are able to utilize Millinocket Stream in a limited capacity to introduce youth to paddling. If This river stretch has more consistent boatable flows this will only increase opportunity for local youth to have something fun and exciting outside of their tablets and phones. The nature of the whitewater on this stream is absolutely perfect for the novice paddler. Its opportunities are the most diverse of all stretches considered in this re-licensing offering recreation for paddleboards, Canoes, and Kayaks.

As a taxpayer, a citizen of Maine, and the United States. It is my belief that it is the duty of the Federal Energy Regulatory Commission to ensure that GLH adequately studies and documents all recreational boating opportunities before any policies, stipulations, and requirements are set in stone for an operating license that will last past the retirement or death of all parties involved in the process. We owe it to our future generations to fully understand the potential of the recreational value of these sights before they are shelved and forgotten about for the next 35 years.

Susan Adams, Patten, ME.
I am writing to share my enthusiastic support for flow studies that will help evaluate recreational opportunities and the ecological well-being of the Ripogenus Dryway, the West Branch below Stone Dam, and Millinocket Stream. These waterways are of profound importance to our local communities and the future of our region. We raised our son and spent 1/3 of our lives along the West Branch and are very interested in its well being and protection for future generations. Thank you
Susan Adams

**Reference: Ripogenus Hydroelectric Project (P-2572-133)**

**RE; West Branch of the Penobscot River below McKay Station, the need to Study and Develop Habitat Based Minimum Flows and the failure to provide flows into the Holbrook Bypass Channel (Article 406 of the WQC)**

Lake level and flow management of the Ripogenus and the North Twin Projects are vastly different from operations described in the 1996 EIS. The Licensee, an international company, is selling a Maine resource (electricity) to a foreign country, New Brunswick, CA. Long gone are any local public benefits. The use of water storage and flow and the need for power have changed since the 1996 FERC License. Great Northern Paper (GNP) Mills are gone and with the mill closure the need to protect the recreational based local economy is more important than ever. Angling, boating, tourism, snowmobiling, etc., are all important within the project areas. A number of studies are needed including the need to develop a West Branch of the Penobscot River (West Branch) operating minimum or environmental flow (sometimes referred to as habitat based flow) below McKay Station. The present use of a minimum Aquatic Based flow or any generic flow prescription, that is not based on habitat; depth, substrate, flow, velocity, and species life stage is archaic and inappropriate and thus unacceptable.

In the good old days (circa 1900-2005) the mill operator used hydropower for baseload operations. A minimum of 2000 cubic feet/sec (cfs) was established by the legislature as part of the original charter granted to the mill developer at the turn of the twentieth century. That flow was established for the West Branch at Millinocket (P-2458) as the minimum flow. The 1992-1996 FERC licensing process established a minimum flow at the upstream McKay Station facility with the understanding that this flow was primarily for periods when the Millinocket and East Millinocket mills needed to be shut down. In fact, selling West Branch power into the grid was by and large not an option because the tie-line to the grid was weak. Now the mills are gone and the Licensee, a major player in National energy markets calls the shots. There is no local manufacturing baseload need to drive the conservation of water to assure paper can be made 24/7/365. The value of waterpower on the open market drives the use of water

storage. A dollar made today from selling the water is worth more than the uncertain value of the selling later in the year. The fish, bugs, loons and other flora and fauna get what the market dictates. A fundamental rebalancing of basic 21st century environmental requirements vs 19th century robber-baron mentality is called for.

Regarding the West Branch below McKay Station the 1996 EIS states “fishing quality is high at 0.41 fish per day. The average size is 18.2” and 2.2 pounds” (EIS 3-37). The existing fishery is now concentrated in the 1.25 miles below McKay Station (communications with WB anglers). An eighteen inch salmon is now a trophy (personal communications and observation) rather than the historic norm. The EIS states the West Branch below McKay Station is a unique fishery. This is not the current situation, fisheries and aquatic communities need to be returned to 1980’s and 1990’s levels described in the EIS and the accompanying 401 Water Quality Certification and deserve full protection. Lake level and river flow (minimum flow, ramping) management are the primary component of needed studies.

The change to peaking power and the resulting Lake level management (or lack thereof) have impacted fish, aquatic invertrabrates, plankton and fishing opportunity. Landlocked Atlantic salmon (salmon) and rainbow smelt populations in the Ripogenus Impoundment waters (five basins and the West Branch) are in a death spiral (DIFW 10/8/2021 filing). In the West Branch, aquatic insects e.g., Ephemeroptera (mayflies), Plecoptera (stoneflies) and Trichoptera (caddisflies) are fewer. Konrad et al (2008) reported alteration to macro invertrabrate communities, including lost taxa, resulting from changes in timing, magnitude and duration of flow. Armanini et al. described the impacts of Magpie River hydropeaking (a Brookfield project) on macro invertrabrates and the benefits of ramping. In order to prevent further degradation of fish and aquatic communities, and interim environmental flow needs to implemented and a habitat based operating flow needs to be developed and become a condition of any new license issued by FERC.

A major impact on the fish and aquatic communities is the licensee’s inappropriate and continued use of the licensed minimum flow below McKay Station as a diel parameter. Such operations stress the aquatic communities. Late this summer the licensee reduced peaking flows in the early evenings to the licensed minimum. The licensee controls storage and flow and if it so chooses, can refer to Water Management Plan and rule curve (storage over time) for long term planning. Around mid-May, 2021 there was approximately 33 billion cubic feet (bcf) available in storage (25 bcf in the Ripogenus Impoundment, 8 bcf in the upstream Storage Project (P-2624)) and another 6 BCF in inflow though September 15. There are many PM&E measures that could have been supported with 39 BCF. However, the licensee deliberately continued daytime peaking operation while using the project’s licensed minimum of 1000 cfs during the night to slow the impact of rapidly declining impoundment

storage. This element of McKay Station 2021 operations drained the Ripogenus Impoundment and eliminated critical lacustrine e.g., littoral zone(s) and riverine habitats e.g., dewatering of the Holbrook bypass channel (WQC Art 406), and frequent dewatering the shoreline and microhabitats, **Troelstrup** et al. (1990) below McKay Station. This policy needs to be enforced.

The deliberate dewatering of the Holbrook bypass channel, a license condition (401 CWA, Article 406), is alarming. This condition, a PM&E measure, was designed to mitigate for the lack of salmon nursey (fry) habitat in the West Branch. The 1996 EIS (4-19) estimated that the Holbrook bypass (Article 406) would contribute 235 three year old adult salmon or approximates 550 adult fish to the West Branch salmon population as this age class is carried though it's age III to age VI cycle. The loss of this year class accompanied by similar loses of fry and parr in other very limited nursey areas and further degrades the salmon fishery. July though mid September storage and flow levels were entirely under the licensee's control. Low flow periods e.g. 1000 cfs, during August and early September nights were entirely preventable**. Holbrook low flows continue today, it is unlikely that there will be any bypass channel salmon spawning/incubation success this winter (2021-2022) as any November egg deposition will be subject to extreme freezing, another salmon year class and the accompanying 550 adult production will be lost. These low flow events not only violated a license condition (article 406) but also violated Maines's Anti-degradation policy. FERC needs to act on this violation.**

**It also should be noted that the current 1000 cfs spawning and incubation flow that was initiated in October, before the salmon spawning season, is not empirically based. I surveyed West Branch spawning areas for fifteen years, there is no evidence that the quality, quantity and location of spawning habitat available at current flows (1000 cfs) will meet reproductive goals. The assumption that favorable (gravels, velocity, interstitial flows) conditions can be transformed upstream, downstream or latterly has not been proved. Salmon spawning and spawning success requires physical conditions, substrate, depth and accelerating flows, described in Volume VIII of the license application and in the EIS, and eggs are vulnerable to freezing during winter months and siltation in the spring resulting from higher snow melt flows. The West Branch salmon population shouldn't be a victim of poor water management, the lack of spawning success and subsequent juvenile habitat reductions puts future salmon age classes in jeopardy. Another PM&E lost**.

From the licensee's PAD/NOI filings and presentations it appears that the licensee will continue to use minimum flow operations as needed e.g., when energy demands are low. The use of the license minimum flow is inappropriate and not the intended use of the West Branch minimum flow set by the agencies, NGOs and GNP in 1992. At that time, GNP mills were producing paper 24 hours a day and the only issue was the short-term protection of salmon (aquatic communities were not directly considered). How the final licensed 1996

minimum flow was derived is confusing. Initially the minimum flow recommended by the agencies was 1455 CFS then 1300 CFS and finally the current 1000 CFS which was derived from an Aquatic Based Flow (ABF) formulae but also met optimal McKay Station turbine efficiency. In any event, daily low flows of 1000-1455 CFS do not provide the habitat protection necessary to support the world-class West Branch salmon fishery and aquatic communities. There is an obvious and immediate need to correct minimum flows requirements and the rate of change (ramping) of West Branch flows below McKay Station. The need for ramping applies to all the licensee's tailwater reaches.

The Licensee' use of (any) ABF minimum flow is simply not appropriate. The U.S. Fish and Wildlife Service added this declaimer in its 1981 ABF policy insurance;

*U.S. Fish and Wildlife Service (1981) developed a "New England Aquatic Base Flow Policy" (ABF). The policy recommended use of the August median streamflow as the minimum streamflow for summertime maintenance of habitat for biota. This minimum streamflow was selected because "low-flow conditions occurring in August typically result in the most metabolic stress to aquatic organisms due to high water temperatures and diminished living space, dissolved oxygen, and food supply"*

The use of any generic minimum flow standard e.g., Tennent, ABF, Montana, 7Q10, etc., as an operational minimum for the West Branch below McKay Station is inappropriate. It uses flow guidance, ABF in this case, for an unintended purpose. Aquatic biota is not directly considered in hydrological "desktop methods". ABF flow methods (flow prescriptions vary with month) use only mean flows and were developed in rivers/streams NOT inhabited by adult landlocked salmon and Hydropsychidae caddis. Thus, the assumption that since these (low) flow conditions (usually August) existed naturally and fish species survived, then similar low flows would provide protection is incorrect. Protection of West Branch ecosystems, in the unlikely event any protection exists at 1000 cfs, is not enhancement. Only Tennant (1976) seemed to recognized the need to define various levels of protection; 10% of mean annual flow (MAD) for minimum protection, 30% MAD for moderate protection and 60% MAD for quality protection. The current West Branch minimum flow (no matter how it was derived) does not provide the high level of protection needed for the world class salmon fishery and aquatic communities downriver of McKay Station. The habitat of this reach is high gradient. It is mostly a narrow channel filled with rock, boulder and ledge substrates, any minimum/environmental flow prescriptions need to be habitat based.

The USFWS Aquatic Base Flow Policy was specifically established as "Many applicants either do not need or do not have sufficient time or resources to conduct a site-specific instream flow study". This is certainly not the case here; Brookfield (the licensee) is a multi-billion dollar international corporation with

vast resources to conduct a proper, field based instream flow study of the West Branch. Furthermore, the USFWS ABF Policy also states: "Site-specific studies such as the Instream Flow Incremental Method may be appropriate when: complex negotiation processes are involved; the project itself is complex; the waters are allocated or over-allocated; several flow alternatives need to be considered and compared against one or more baselines; complex administrative proceedings are involved; and time and costs are not major constraints." This exactly describes the current relicensing of the Ripogenus and Penobscot Mills Projects.

In order for FERC to conduct an adequate assessment of habitat vs flow in the West Branch of the Penobscot River as part of their NEPA analysis, transects must be established from McKay Station downstream to its confluence with Ambajesus Lake and then from North Twin Dam downstream to the confluence of the East and West Branches of the Penobscot River. Data including substrate, depth, and velocity must be collected over a range of flows to allow habitat vs discharge relationships to be established for various salmon and macro invertrabrate life stages. Absent these data, the Commission will not be able to conduct a thorough NEPA analysis.

Ahmadi-Nedushan, Behrouz, et al. (2006) described factors needed to determine suitable flow regimes. "*Physical habitat structure is of paramount importance in determining both the abundance and species composition of stream fishes (e.g. Allan, 1995; Bovee et al., 1998; Peeters and Gardeniers, 1998; Vadas and Orth, 2001). The most important physical habitat variables include water depth (e.g. Geist et al., 2000; Guay et al., 2000; Beecher et al., 2002; Kynard et al., 2000), water velocity and flow (e.g. Geist et al., 2000; Kynard et al., 2000; Mallet et al., 2000; Peeters and Gardeniers, 1998), cover (e.g. Vadas and Orth, 2001) and substratum composition (e.g. Knapp and Preisler, 1999; Vadas and Orth, 2001). Water velocity and the associated physical forces collectively represent the most important environmental factors affecting the organisms of running waters.".* ABF methods are based on median flows across a given geographical region. Depth and velocity are not part of the equation nor are any of the other critical parameters listed above

The science of flow, habitat and their relationship to aquatic species has changed since 1992 The magnitude and timing of flow change and its relationship to base flow is now part of the equation. Hunter M.A. (1992) reported that a slight flow change of one to two inches an hour was needed to support juvenile salmon West Coast salmon.. Relationships between habitat based minimum and peaking flows have been reported in the literature. These authors evaluated minimum flows and peaking. The general conclusion was that higher minimum/environmental flows at the starting point provided greater protection from peaking events. Bain et al. (1988) reported that high frequencies of flow change reduced both the abundance and number of species. Irving et al. (2014) reported that stranding was reduced when the magnitude of

flow change was lessened and noted that channel configuration and season influenced (pacific coast) salmonid behavior. Greimel et al. (2018) suggested high base flows would reduce the impact of peaking. Travnichek et al (1995) found that an increased minimum flow mitigated, to some degree, the impact of peaking on Tallapoosa River fish populations. Bunn & Arthington, (2002) reported that magnitude, frequency, and timing of flow change determined aquatic impacts and Poff et al. (1997) added rate of change to likely impacts. McKinney **et al (2001) studied rainbow trout populations (stocked and wild fish) in the Colorado River below Glen Canyon Dam. Trout populations responded positively to an increased minimum flow and reduced daily flow fluctuation. Growth and abundance of wild trout improved following the 1991 modification of the flow regime.** Behrouz et al. (2006) provides a detail examination of modeling used in determining flow management options.

**The above paragraphs describe continuing Ripogenus Project impacts resulting from present project operations and the need for immediate action. The structure of fish and aquatic communities described in the EIS was based on an operating minimum of a "two wheel" (turbine) operation. This flow was based on turbine efficiency (maximum McKay Station turbine efficiency was 92-96 % of flow capacity) and resulted in a base flow of 2200-2400 cfs. As an interim measure, FERC should require an operating minimum flow of 2300 cfs beginning at the end of the 2022 snow melt. I thank FERC in advance for considering my recommendations for returning project waters to 1980s and 1990s levels needed to support the world class salmon fishery and healthy aquatic communities. The fish, bugs and anglers need FERC's help**.

TROUT UNLIMITED
MAINE COUNCIL

**Via online submission to: http://www/ferc.gov (cross-filed)**

Subject: **Comments of Maine Council of Trout Unlimited on the Proposed Study Plan for the Ripogenus Project (P-2572) and the Penobscot Mills Project (P-2458)**

Dear Secretary Bose:

On behalf of its six chapters and over 2,000 members, Maine Council of Trout Unlimited (TU) submits these comments on the Proposed Study Plan (PSP) for the Ripogenus Project (P-2572) and the Penobscot Mills Project (P-2458) filed for Great Lakes Hydro America, LLC by Brookfield Renewable ("Brookfield" or "Applicant") dated November 22, 2021.

**General Comments**

The Applicant began the PAD stating that the full suite of studies is not needed.[1] It has gone on to review the 35 study requests submitted by organizations and only proposed conducting 3 without modification, accepted 13 more with modification or included them with other studies, and rejected 19 outright. The Applicant calls the proposed studies a "determination."[2] The study plan determination is a FERC function, not one made by the applicant. The applicant continues to propose acceptance of predominantly 30-to-40-year-old studies. This is confusing and delaying effective progress through the ILP relicensing process.

TU combined with Appalachian Mountain Club ("AMC"), American Whitewater ("AW"), Caribou, Chesuncook Lake Camp Owners Association, Chesuncook Dam Camp Owners Association, the Allagash Gateway Campground, and Andre Emerson Cushing Corporation to submit joint preliminary PSP Comments that addressed our underlying concerns regarding the current status and direction of the relicensings.[3] Please consider the contents of that filing when reading and evaluating the merits of this one.

[1] Brookfield Notices of Intent and Pre-application Documents for the Ripogenus Project (P-2572) and the Penobscot Mills Project (P-2458) dated June 11, 2021, page 1-11. "*GLHA maintains that a full suite of new studies is not needed, that the vast body of information on which today's certifications and licenses are soundly based and should be relied upon for these relicensings. In addition, consistent with the Commission's criteria for study requests, the scope and extent of any new study be focused on addressing specific data gaps necessary to inform the development of license requirements.*"
[2] PSP, page 1-19, Table 1-1 title: "*Stakeholder Study Requests for the Ripogenus and Penobscot Mills Project and GLHA's Determination.*"
[3] TU filing of February 10, 2022, Accession number 20220210-5189.

**Maine TU Council Study Requests:**

**Ripogenus Flow Excursion Study.** TU's PAD Comments[4] requested a study to document the stability of flows from Ripogenus Dam as they compare to the licensed project minimums and to conduct a 400 cfs flow demonstration to determine the impacts of "generator outage flow" on aquatic organisms.

Brookfield rejected the study request explaining that their Historical Operations Data and Assessment Study would document any such deviations from project minimums;[5] **Brookfield ignored the included request to conduct a 400 cfs flow demonstration to evaluate the impacts of these flow levels.**

Brookfield is well aware of this type of study: one was conducted a few years ago in concert with the Penobscot Project, P-4784. Additionally, as Maine TU Council stated in its PAD Comments[6] Brookfield itself had made preparations for demonstration of the effects of flows below licensed minimums for its Wyman Project, P-2329 for the summer of 2021 but never conducted the event.

The effects of 400 cfs below McKay Station on aquatic organisms is currently not known. Projects operations could mitigate the effects of such events if they are truly unavoidable or uncorrectable using technology available. An obvious example would be to continuously release some water through a deep gate lessening the impact of flow reduction to 400 cfs through the turbines. Deep gate releases have been used successfully in the past to maintain flows at Ripogenus Dam.[7]

The following provides the FERC Study Request for a Stranding Evaluation Study.

## Stranding Evaluation Study

***Goals and Objectives***

The study will provide information regarding the potential for fish stranding associated with the Ripogenus Project. The study objective is to determine the extent and degree of danger stranding pools that occur from below the McKay Station discharge to Nesowadnehunk Falls, especially under 400 cfs generator trip events.

***Known Resource Management Goals*** (Under §5.9(b)(3) If the requester is a not a source agency, explain any relevant public Interest.)

The requestor, Maine Council of TU, is a non-governmental organization (NGO).

Maine's rivers, great ponds and wildlife are, by law, public resources. The West Branch of the Penobscot is one of the areas in Maine that TU members most prefer for fishing and other recreational activities, and thus TU has a direct interest in the waters affected by project operations, especially those from Ripogenus Dam to below Nesowadnehunk Falls.

[4] Maine Council of Trout Unlimited letter dated October 9, 2021, Subject: Comments of Maine Council of Trout Unlimited on the Notices of Intent and Pre-application Documents for the Ripogenus Project (P-2572) and the Penobscot Mills Project (P-2458)

[5] PSP, Part 1, page 3-14.

[6] TU PAD Comments dated October 9, 2021, page 19.

[7] Brookfield Letter dated August 24, 2015, page 2.

***Background and Existing Information***

There is no existing information regarding stranding-prone areas or operational scenarios for the Ripogenus Project. This study is needed to quantify project effects on a potential source of fish mortality and injury.

***Project Nexus***

Generator trip events at McKay Station occur with some frequency and it is a matter of record that two such events occurred during the August-September timeframe of 2021 when strandings were photographically documented.[8] It is hard to image aspects of project operations that could have a more direct relationship with the welfare of aquatic organisms than immediate, drastic flow reductions.

***Methodology***

Task 1: Operational Data Review:

> Prior to conducting the field investigation, a desktop literature review will be performed to gather information on the range of flows when generator trip events are likely to occur. We anticipate that since thunderstorms occur during the summer, whitewater flows generally of 2200 – 1800 cfs would generally be in effect when the outages occur.

Task 2: Field Surveys:

> The field survey will consist of a reconnaissance level evaluation where a field crew will examine potential stranding sites in the study area at an appropriate time interval after spilling operations have ceased. Any accessible pools with fish stranding potential will be identified and visited shortly after the spillage event. On-ground surveys will traverse any pools and visually document fish present as well as looking for fish trapped under rocks. Information on the number and location of fish stranded will be recorded. In addition, the conditions of the study area will be photo-documented.

***Consistency with Generally Accepted Scientific Practice***

The proposed survey to document potential stranding areas is an accepted means of documenting species use in the Project area.

***Deliverables and Schedule***

The survey effort will be conducted during the summer/fall of 2022. Data and results will be included in the Initial Study Report to be filed with FERC in 2023.

***Cost and Level of Effort***

The estimated cost for the stranding evaluation is approximately $20,000. This level of effort is consistent with the size of project operations.

The Applicant may be able to combine this study with any testing of equipment and procedures ordered by the FERC Compliance Division as part of its investigation in the low flow events previously referenced, especially generator trip events. This could provide significant cost savings lowering the cost estimate provided above.

[8] TU Letter dated September 21, 2021, Subject: Maine Council of Trout Unlimited Report of Observed Low Flow Events for the Ripogenus Project (P-2572); TU Letter dated January 5, 2022, Subject: Maine Council of Trout Unlimited Amplifying Report for Observed Low Flow Events for the Ripogenus Project (P-2572).

TU supports the study request made by Ed Spear for a "Ramping and the Need to Determine the Appropriate Rate of Flow Change Below McKay Station"[9] as an appropriate and valuable follow on to the stranding study.

**Baseline Fisheries Assemblage Studies.** Ten individual study requests were submitted in TU's PAD Comments that correspond to the reaches where assemblage studies were specified and included in the PAD. Brookfield rejected the study requests in toto without addressing each request specifically. Brookfield says that the fish assemblage data exists but does not provide it in anything resembling an organized manner. In the PSP Teleconference, Brookfield implied that providing this information is a MDIFW responsibility. It is not, and fisheries information is addressed specifically by 18 CFR § 5.6 (d)(3)(iv) as a PAD requirement.

Maine TU Council requests that Brookfield provide all the fish assemblage information as a coherent report. Conducting some of the specific fisheries assemblage studies contained in our prior request may be the only way for that to be ultimately accomplished. Current fisheries assemblage data should have been provided in the PAD, not the information from the last relicensing. Brookfield's actions thus far have served to confuse and delay the provision of information specifically required by 18 CFR § 5.6.

**Other Studies:**

Maine TU Council will continue to support the studies supported in our PAD Comments:

1. MDIFW for these proposed studies that bear directly on their ability to manage resident species:
    1) Exposed Aquatic Habitat Assessment
    2) Landlocked Salmon Habitat Use/Spawning Study—Penobscot Mills Project
    3) Minimum Flow Analysis of Back Channel [West Branch below Stone Dam]
    4) Macroinvertebrates Study Request—Ripogenus Project

2. NMFS for these flow and temperature related studies. **These studies are essential to establishing appropriate terms and conditions for the relicensing.** Without data and analysis of flow and temperature to inform the process, it will be impossible to correct the dewatering and other obvious problems associated with the projects caused by the permissive operating parameters granted under the last relicensing to cater to the Millinocket paper mills. TU fully supports inclusion of these studies for the reasons stated in detail by NMFS in its PSP Comments.[10] While these studies are fully justified on the basis of effects on Atlantic salmon, the information would be invaluable for determining the effects of flows on resident fish species and other aquatic organisms as well:
    1) A Study to Evaluate the Effects of Operating the Penobscot Mills and Ripogenus Dams on the Hydrology of the West Branch and Mainstem Penobscot River Using an Indicators of Hydrologic Alteration Model (IHA)
    2) A Study to Evaluate Project Effects on River Temperature in the West Branch and Mainstem Penobscot River
    3) A Study to Evaluate Future Flow and Water Temperature Scenarios

[9] Ed Spear Letter dated February 12, 20022, Accession number 20220214-5027.
[10] NMFS letter dated February 17, 2022, RE: Comments on Great Lakes Hydro America, LLC (GLHA) Proposed Study Plan for the Ripogenus Hydroelectric Project (FERC No. 2572) and Penobscot Mills Hydroelectric Project (FERC No. 2458).

TU continues to support the NMFS request for operational data that Brookfield has yet to supply.[11]

3. MDMR for studies for American eels and passage alternatives for all historic anadromous species:

1) Three-Dimensional Computational Fluid Dynamics (CFD) Modeling Upstream and Downstream of the Discharge and in the Vicinity of Powerhouse Forebays
2) Upstream Juvenile Eel Assessment
3) Downstream American Eel Passage Assessment
4) Downstream Passage Alternatives Study
5) Upstream Passage Alternatives Study
6) Evaluation of the Size of American Eels and the Timing of their Downstream Migratory Movements

4. USFWS for the following due to their potential positive impact on the ecology of the entire Penobscot Watershed:

1) Upstream American Eel Passage Assessment
2) Downstream American Eel Passage Assessment
3) Downstream Passage Alternatives Study [eels]
4) Evaluation of the Size of American Eels and the Timing of their Downstream Migratory Movements
5) Freshwater Mussel Survey

5. American Rivers and the Appalachian Mountain Club for the following: aesthetics and other uses are also important to TU members. The first study is absolutely essential to identify changes that have occurred since the last license was issued and to identify needs for the next licensing period. Whitewater flows have proven to be highly compatible with fishing-related activities on the West Branch. Care must be taken to assure commensurate minimum flows:

1) Recreation Facility Inventory, Recreation Use and Needs Assessment, Aesthetics and Reservoir Surface Area Assessment Study
2) Controlled-flow Whitewater Boating and Access Study
3) Aesthetics Resources Study

6. The standard MDEP suite of study requests conditioned to provide sampling in the generally dewatered reaches of the main stem of the West Branch of the Penobscot River in upper Ripogenus Gorge and below Stone Dam. While the specific legislation allows major changes to the littoral zone, with the severe changes to impoundment levels that have been extensively documented by numerous photographs and comments, the limnetic and profundal zones have likely been impacted as well. Study is indicated, and this does not represent a conflict with the statutory language

7. TU additionally asks that Brookfield either accept the socioeconomics study request submitted by the Penobscot Indian Nation[12] or acknowledge that there has been a significant change in the economics and demographics of the region since the mills have closed. While the comments submitted by Economics Professor Sharon Klein more than justify the study,[13] it would be

[11] Ibid.
[12] Penobscot Nation letter dated October 12, 2021, RE: Penobscot Mills (P-2458-247) and Ripogenus (P- 2572-133) Notice of Intent, Pre-application document, Scoping document #1 and study requests.
[13] Dr. Sharon Klein Letter dated February 18, 2022, RE: Penobscot Mills (P-2458-247) and Ripogenus (P- 2572-133) Proposed Study Plan.

preferable that the Applicant simply acknowledges the obvious, that the regional economic situation has significantly changed, as a show of good faith going forward in the relicensing process.

8. Maine TU Council will also support the other MDIFW study requests. Ripogenus-Chesuncook water levels are inextricably linked to the general ecology of the region, its wildlife and the fish both in the impoundment and the flowing waters of the West Branch.

9. Brookfield is not complying with FERC requirements regarding recreational facilities information, specifically 18 CFR § 5.6 (d)(3)(vii) and (ix). Studies need to be conducted to identify potential access sites that will need to be created when the reach of the West Branch below Stone Dam is continuously watered.

10. Our final comment in this section involves the Study to Evaluate the Effects of Operating the Penobscot Mills and Ripogenus Dams on the Hydrology of the West Branch and Mainstem Penobscot River Using an Indicators of Hydrologic Alteration Model (IHA) referenced and supported above. Currently Ripogenus Gorge is watered only nine months of the year and then only with 100 cfs. It is important that this study address macroinvertebrate production over a range of flow scenarios. The waters below McKay Station contain as abundant macroinvertebrate populations as anywhere in the state. The project dewaters areas of the gorge upstream of McKay Station that could be just as abundant. Increased abundance would be expected to produce gains in salmonid size quality and abundance downstream. Water in the upper gorge would also provide enhanced aesthetics of the views of Maine's most significant gorge from the trail above. Water in the upper gorge would also buffer the effects of generator outage flows by being additive to the 400 cfs flows through the generators. Accordingly, evaluation of all these factors under a range of flow conditions is essential to maximizing use of the resource that the West Branch of the Penobscot below Ripogenus Dam represents.

**Administrative Comments**

1. All official comments submitted for these relicensings that bear the TU logo were the product of the Maine TU Council FERC Committee, were approved by the then Chair of Maine TU Council C. E. (Mac) McGinley, and are consistent with Maine Council and TU National policy and the TU mission. Further TU comments will have been approved or signed by his successor Matthew Streeter as Maine TU Council Chair.
2. Each page of the PSP contains the annotation "*Copyright © 2021, Great Lakes Hydro America, LLC. All rights reserved.*" Per our prior comments: "*The FERC process is a public one that actively seeks comments from the public. While these notations were appropriate to the documents before they were filed to the FERC dockets, once they were posted, the document became part of the public domain. Accordingly, the notation became incorrect the moment the document was filed. Including it can only serve to confuse those unfamiliar with the process, and discourage use of the filing in the media. The notation should NOT be included in future filings for these relicensings."*[14]
3. TU has still not received studies referenced in the Pre-application Document (PAD) but not included. These were requested multiple times by TU.[15] Brookfield has provided web addresses not

[14] Maine TU Council PAD Comments dated October 9, 2021, page 3.
[15] Id., page 14.

documents. Brookfield has yet to provide a compilation of fisheries information required by 18 CFR §5.6.

Respectfully submitted,

Matthew Streeter
Maine TU Council Chair

RE: Comments on the Proposed Study Plans for the Ripogenus (FERC No. 2572) and Penobscot Mills (FERC No. 2458) Hydroelectric Projects

Dear Secretary Bose:

The Maine Department of Environmental Protection (Department) received and reviewed Proposed Study Plans submitted on November 22, 2021 by Great Lakes Hydro America, LLC (GLHA, or Applicant), a subsidiary of Brookfield Renewable, for the Ripogenus and Penobscot Mills Hydroelectric Projects, located on the West Branch of the Penobscot River. Department staff attended a Proposed Study Plan meeting on December 15 and 16, 2021 and reviewed appropriate Project documents to prepare the following comments, recommendations, and study plans.

As identified in Department comments on the Pre-Application Documents for these projects, the proposed relicensing of the Ripogenus and the Penobscot Mills Projects are subject to water quality certification provisions under Section 401 of the Federal Water Pollution Control Act (a.k.a. Clean Water Act or CWA). By Executive Order of the Governor of the State of Maine, the Department is the certifying agency for water quality certifications.

Comments on the Relicensing Study Plans

The Department appreciates the effort of the Applicant to prepare the Relicensing Study Plans. Project study plans must be designed to evaluate the impact of project operations with respect to all of Maine's applicable water quality standards, including designated uses and both narrative and numeric criteria. Water quality classification in the West Branch Penobscot River has been proposed for upgrade and so may change in the near term from information around water quality classification and standards that was provided to project proponents in the Department's PAD comments; we will do our best to keep everyone informed of the Legislature's decisions as we move forward.

In addition, the Ripogenus Project was the subject of a use attainability analysis (UAA) at its last relicensing. The UAA found …"it is not possible, feasible or desirable to operate the Ripogenus impoundment in such a way that would maintain the natural standard." EPA, in its approval of the UAA clarified that meeting a natural standard was not at issue but that the UAA needed to demonstrate that the Ripogenus Project precludes the attainment of the criteria in the Class C habitat and aquatic life use, and it is not feasible to operate the dam in a way that will result in the attainment of that use, in part because the aquatic community that has evolved in the impoundment and downstream waters constitute an important fishery resource that would be at risk should the project's operation be significantly altered…".

The UAA resulted in revisions to Maine's Water Classification Program[1] regarding aquatic life and habitat criteria in the impoundment associated with the Ripogenus Development that requires the existing impounded waters (collectively known as Chesuncook Lake but including Ripogenus Lake, Caribou Lake, Brandy Pond, Black Pond, and Moose Pond) remain classified under Section 465-A[2]. Because those impounded waters are subject to water level fluctuations that have an effect on the habitat and aquatic life in the littoral zone so that the habitat and aquatic life differ significantly from that found in an unimpounded great pond and so may be unable to meet GPA criteria for habitat and aquatic life, the project proponent must demonstrate that those waters are able to support all indigenous species of fish and must also demonstrate that the structure and function of the resident biological community in the impounded waters is maintained.

In order to evaluate whether the impounded waters support all species of fish indigenous to those waters, the Applicant must conduct a fish assemblage study in order to draw a comparison to the fish assemblage indigenous to those waters. Typically, such studies are proposed by Maine's Department of Inland Fisheries and Wildlife; although DIFW didn't request such a study Trout Unlimited's fish assemblage study request was declined and so the Department supports TU's request here and has attached its supporting study request.

Additionally, the Applicant must demonstrate that all designated uses are met in Project waters, including navigation. The designated use of navigation has been questioned by property owners and users of the Ripogenus impoundment, who indicate that access to the impounded waters is not sufficient at all times, particularly when the water is drawn down. The Applicant must demonstrate that access to Project water is available throughout the recreational season.

Water Quality Monitoring Studies - Department Study Requests

Impoundment Aquatic Habitat and Aquatic Life. The Proposed Study Plan indicates the Applicant intends to use standard macroinvertebrate sampling techniques to evaluate attainment of aquatic life criteria in the Ripogenus impoundment, however macroinvertebrate sampling in lakes and impoundments requires different methodologies than typically used in rivers. Therefore, the Department requests the Applicant identify the percentage of wetted littoral zone to be maintained and recommends that the Applicant consult directly with Department staff to establish sample locations and methodologies to sample impoundment macroinvertebrates so that data collected is sufficient for the Department to make its determination regarding attainment of applicable aquatic life criteria. The Proposed study plan indicates that the Applicant does not propose to complete an impoundment aquatic habitat assessment for Millinocket (Quakish Lake and Ferguson Pond), Dolby and East Millinocket developments because they are operated as run-of-river facilities. The Applicant must demonstrate that applicable water quality standards, including aquatic life criteria, are met in all Project waters in order to be certified that the Project meets water quality standards. The responsibility to make that demonstration lies with the Applicant and so reliance on operational mode means that submission of flow and water level data at each of those impoundments will be required to demonstrate whether the Project adheres to the run-of-river operations at all times.

[1] See 38 M.R.S. § 464(9-A)(A).
[2] 38 M.R.S. § 465-A provides classification standards for great ponds and natural lakes and ponds less than 10 acres in size, and includes impoundments of rivers that are defined as great ponds pursuant to section 480-B because they are greater than 30 acres in size.

Riverine Aquatic Habitat. The Proposed Study Plan indicates the Applicant intends to study riverine aquatic habitat at the Ripogenus Development only in the upper gorge, and will collect measurements of water depth, water velocity, wetted width, substrate types and zone of passage conditions. The Department does not oppose collection of those metrics, but requires that the Applicant analyze the data to determine the flow at which at least 75% of the bankfull cross-sectional **area** is continuously watered. Further, the Department does not agree that data collected in previous relicensing efforts demonstrates the impacts of Project operations on the resource and reiterates here that the riverine aquatic habitat below McKay Station must be studied to demonstrate that proposed Project operations meet the applicable habitat criteria, particularly whether 75% of the cross-sectional area remains watered at all times, compared to bankfull conditons. Reliance on studies conducted during prior relicensing efforts do not demonstrate attainment of applicable aquatic habitat or aquatic life criteria under the operating regime conditioned by that license. A demonstration of attainment is necessary for a fully informed water quality certification. Further, the highly variable flows downstream of the Project dam can affect habitat, including the potential for fish and other aquatic life to become stranded in ledge pools as water levels rise and fall as a result of flow variations. Of particular concern to Trout Unlimited are the station trip flows (400 cfs) and whether such flows adequately maintain 75% of the wetted area downstream of the Project, and whether sudden reduction in flows to 400 cfs cause fish to become stranded. The Department supports TU's study request as it relates to Project operational flows on the riverine habitats affected by the Project.

With respect to the Penobscot Mills Project, the Department reiterates here that GLHA must demonstrate that at least 75% of the cross-sectional area of the outlet streams (including Millinocket Stream and the West Branch of the Penobscot River) are wetted at all times. The proposed study plan is not specific as to how the Applicant will make that demonstration but indicates it will collaborate with the Department on its re-evaluation.

Thank you for the opportunity to review and comment on proposed studies for the Ripogenus and the Penobscot Mills Hydroelectric Projects. In addition to the attached Study Request for a fish assemblage study to demonstrate attainment of habitat criteria in the Ripogenus impoundment, the Department supports the study requests of other agencies and non-governmental organizations.

Sincerely,

Kathy Davis Howatt
Hydropower Coordinator
Department of Environmental Protection

Maine Department of Environmental Protection

Study Request

Ripogenus Hydropower Project (FERC No. 2572)

**Impoundment Fish Assemblage Study**

1. **Describe the goals and objectives of each study proposal and the information to the obtained.**
   Fish assemblage within the Ripogenus impoundment is an important metric to establishing that Project operations meet water quality standards, including a special law enacted by Maine Legislature for this impoundment. Assessment of this criteria provides information to evaluate the aquatic habitat of the Ripogenus impoundment, including the waters of Ripogenus Lake, Caribou Lake, Brandy Pond, Black Pond, and Chesuncook Lake and the impact of the dam structure and operation on those habitats and on the fish assemblage in the West Branch of the Penobscot River that drop out of the lake and into the river. The objective of this study proposal is to determine if the project impoundment meets Maine Water Quality Standards, including that the existing impounded waters are able to support all species of fish indigenous to those waters, and demonstrating, in part, attainment of the designated use of habitat for fish and other aquatic organisms.

2. **If applicable, explain the relevant resource management goals of the agencies or Indian tribes with jurisdiction over the resource to be studied.**
   The resource management goal is to ensure attainment of Maine Water Quality Standards pursuant to the provisions of the ***Water Classification Program***, 38 M.R.S. Sections 464-468 and to certify attainment of such, with any necessary conditions, under Section 401 of the Federal Water Pollution Control Act (a.k.a. Clean Water Act).

3. **If the requestor is not a resource agency, explain any relevant public interest considerations in regard to the proposed study.**
   Requestor is a resource agency.

4. **Describe existing information concerning the subject of the study proposal, and the need for additional information.**
   The Proposed Study Plan presents studies planned by the Applicant to investigate the impacts of operations and proposed operations of the Ripogenus Hydroelectric Project, however the applicant does not propose to conduct a Fish Assemblage Study to demonstrate whether the Project meets the requirements of Maine Law related to aquatic habitat in the Ripogenus impoundment. The Applicant will need to demonstrate that the project operation supports all species of fish indigenous to those impounded waters.

5. **Explain any nexus between project operations and effects (direct, indirect, and/or cumulative) on the resource to be studied, and how the study results would inform the development of license requirements.**
   Data collected will identify the presence and relative abundance of fish species present and will be used to demonstrate effects of Project drawdowns on the resident fish. Information will be used to evaluate whether the project meets Maine designated use of the Project waters' habitat and aquatic life criteria, which will inform the water quality certification process.

6. **Explain how any proposed study methodology (including any preferred data collection and analysis techniques, or objectively quantified information, and a schedule including appropriate filed season(s) and duration) is consistent with generally accepted practice in the scientific community or, as appropriate, considers relevant tribal values and knowledge.**
   The Department does not regularly request fish assemblage studies and so will rely on established study protocols used successfully throughout the State by the Applicant and others.

7. **Describe considerations of level of effort and cost, as applicable, and why proposed alternative studies would not be sufficient to meet the stated information needs.**
   A survey of resident and stocked fish should be made during open water season and should include each basin that comprises the Ripogenus impoundment. A fish assemblage study can be completed in one field season. Costs are considered reasonable given that this study is required for Maine water quality certification and is routinely completed at hydropower projects being relicensed in the State. No alternatives to this study are proposed.

**Subject: Comments of the Atlantic Salmon Federation on the Proposed Study Plan for the Ripogenus Project (P-2572) and the Penobscot Mills Project (P-2458)**

Dear Secretary Bose:

The Atlantic Salmon Federation ("ASF") hereby submits the following comments on the Proposed Study Plan (PSP) for the Ripogenus Project (P-2572) and the Penobscot Mills Project (P-2458) filed for Great Lakes Hydro America, LLC by Brookfield Renewable ("Brookfield" or "Applicant") dated November 22, 2021.

ASF is an international non-profit organization dedicated to the conservation and restoration of the wild Atlantic salmon and its environment. ASF represents more than 8,000 members in the United States. We also represent more than a dozen affiliated local conservation and watershed groups across the State of Maine via our Maine Council, representing more than 2,000 additional volunteers and supporters. ASF has a long history of advocating for the restoration of the Penobscot River ecosystem and its native fisheries, and has also invested (and is continuing to invest) substantial time and funding to open-up significant quantities of historic habitat in all corners of the watershed through myriad on-the-ground habitat restoration and connectivity projects.

**General Comments**

The Applicant stated in the Pre-application Document (PAD) that "…*the Projects operate under an array of highly beneficial and effective PM&E measures that enhance aquatic and terrestrial habitats throughout the Project areas, while serving as a critical component for the seasonal management of water flows throughout the Penobscot River Basin. These PM&E measures comprehensively address resource interests specific to the Project areas as well as the larger river basin.* ". [PAD, Vol I, Part 1, page 1-8] This is clearly far from the truth as the multiple pictures submitted by camp owners on the Ripogenus-Chesuncook Impoundment showing severe dewatering of the impoundment clearly demonstrate. This assertion taints the Applicant's assessment of the need for current

studies. For this and other reasons outlined in the joint filing by Maine Council of Trout Unlimited, Appalachian Mountain Club, American Whitewater, Caribou, Chesuncook Lake Camp Owners Association, Chesuncook Dam Camp Owners Association, the Allagash Gateway Campground, and Andre Emerson Cushing Corporation dated February 21, 2022, ASF supports that filing and asks that FERC require Brookfield inform the process using current study data, not studies from the last relicensing. Using this as a basis, Brookfield only accepted three of the more than thirty study requests submitted.

Finally, if Brookfield will not acknowledge that the socioeconomic context of the projects has changed and cease basing its positions on a situation that no longer exists, ASF requests that Brookfield undertake the socioeconomics study request submitted by the Penobscot Indian Nation [Penobscot Nation letter dated October 12, 2021, RE: Penobscot Mills (P-2458-247) and Ripogenus (P-2572-133) Notice of Intent, Pre-application document, Scoping document #1 and study requests.]

**Specific Comments**

The operation of the six dams associated with the Ripogenus and Penobscot Mills Projects dictates the quality, quantity, and timing of water entering the Penobscot River from the West Branch, thus impacting the entire river ecosystem below the Projects. In addition, the presence of these Projects prevents sea-run fish from accessing large quantities of historic habitat within and above the Projects, both impacting the natural ecology of the waters of the West Branch and substantially decreasing the abundance of these species in the Penobscot, further impacting the ecosystem from its headwaters to Penobscot Bay. These Projects directly affect the recovery of endangered Atlantic salmon and impact the species' designated critical habitat and its constituent elements. The scale and magnitude of these impacts is unknown at this point, so it is imperative that the studies associated with relicensing these Projects provide the information requisite to understanding the effects of the Projects. A full understanding of the impacts is the only way to inform the actions necessary to eliminate, avoid, minimize, or mitigate the impacts and thus improve the health and quality of the environment in the West Branch and mainstem Penobscot. As such, ASF supports the following study requests:

1. The requests from the National Marine Fisheries Service for the following key flow-related studies. These studies are justified based on effects downstream on endangered Atlantic salmon:

    1) A Study to Evaluate the Effects of Operating the Penobscot Mills and Ripogenus Dams on the Hydrology of the West Branch and Mainstem Penobscot River Using an Indicators of Hydrologic Alteration Model (IHA)

2) A Study to Evaluate Project Effects on River Temperature in the West Branch and Mainstem Penobscot River

3) A Study to Evaluate Future Flow and Water Temperature Scenarios

2. The requests from the Maine DMR for studies for American eel and passage alternatives for all historic anadromous species:

    1) Three-Dimensional Computational Fluid Dynamics (CFD) Modeling Upstream and Downstream of the Discharge and in the Vicinity of Powerhouse Forebays

    2) Upstream Juvenile Eel Assessment

    3) Downstream American Eel Passage Assessment

    4) Downstream Passage Alternatives Study

    5) Upstream Passage Alternatives Study

    6) Evaluation of the Size of American Eels and the Timing of their Downstream Migratory Movements

3. The requests from U.S. Fish & Wildlife Service for the following studies on American eel and freshwater mussels to inform decisions that will benefit the ecology of the Penobscot Watershed:

    1) Upstream American Eel Passage Assessment

    2) Downstream American Eel Passage Assessment

    3) Downstream Passage Alternatives Study [eels]

    4) Evaluation of the Size of American Eels and the Timing of their Downstream Migratory Movements

    5) Freshwater Mussel Survey

4. The request from the Maine Department of Environmental Protection for its standard suite of water quality studies.

5. The request from Trout Unlimited for fish assemblage studies. The information provided will bear on future efforts to restore Atlantic salmon and co-evolved native species to waters included in the Penobscot Mills Project. Information provided in the PAD was outdated, the applicant has yet to provide the fisheries data required by 18 CFR §5.6 in a coherent manner.

ASF appreciates the opportunity to comment on the PSP for this proceeding. We believe that the study requests referenced above are essential to understand the current project impacts on native fisheries, water quality and flows, instream aquatic habitat, and overall river ecosystem health. The results of these studies will greatly assist the Commission in conducting a meaningful NEPA analysis of the Projects, resulting in a substantially more informed relicensing decision that truly balances the costs and benefits of these Projects.

Respectfully submitted,

John R.J. Burrows
Executive Director of U.S. Operations
Atlantic Salmon Federation

**RE: Comment on PSP, Ripogenus Project (FERC No. 2572) and Penobscot Mills Project (FERC No. 2458)**

Dear Secretary Bose,

On June 11, 2021, with the submittal of the Pre-Application Document (PAD) Great Lakes Hydro America, LLC (GLHA), a subsidiary of Brookfield Renewable, initiated the Integrated Licensing Process (ILP) for the Ripogenus Hydroelectric Project (FERC No. 2572) and the Penobscot Mills Hydroelectric Project (FERC No. 2458) (the Projects). On October 9, 2021, the Bureau of Parks and Lands submitted comments on the PAD, including comments on proposed studies and study requests. GLHA submitted the Proposed Study Plan (PSP) on November 22, 2021.

As stated in our previous comments, the Bureau of Parks and Lands (BPL) is a division of the Maine Department of Agriculture, Conservation and Forestry (MDACF), a cabinet level agency of the State of Maine. As authorized under Section 10 of the Federal Power Act, BPL reviews hydropower projects and provides recommendation to licensees with a focus on the adequacy of existing public recreation facilities and access to meet public needs, the adequacy of flow releases to provide for downstream boating opportunities, and the effect, if any, on public lands and private lands if available for public recreation.

Based on these responsibilities we have prepared the following comments on the PSP:

GLHA Responses to BPL comments on PAD Section 5.8: Recreation and Land Management
BPL commented on five individual topics within this section of the PAD, seeking clarification or correction of the information provided. However, GLHA has not provided substantive responses to the Bureau's comments. Instead, in PSP Appendix J, pages 9-10, GLHA provided the

following response to all five comments, referring to the future Recreation Study: "GLHA is proposing to conduct a Recreation Study (Appendix F of this PSP). Study results will be included in the study report to be filed with FERC in April 2023."

Rather than assume the Recreation Study will provide the necessary information, the Bureau requests that complete and accurate information on Project recreation sites and related topics be provided before the Recreation Study Plan is finalized. We consider accurate and complete information related to these topics essential to the success of the Recreation Study.

1.2.2 GLHA's Proposed Study Plan – Recreation Study

*Assessment of Boat Access to Impoundments*

In Table 1-1, page 1-20, GLHA provide a summary of their responses to BPL's study requests for assessment of boat access to Ripogenus Impoundment, North Twin Impoundment and Millinocket Lake with Drawdown, indicating that the requests were "Not adopted as requested. Portions of Requested Study adopted into other studies." The Recreation Study Plan, found in Appendix F of the PSP, provides the specific responses to our requests, both those that were adopted and not adopted.

The Bureau appreciates GLHA's decision to include assessment of boat access to Ripogenus Impoundment in the Recreation Study, as indicated on page F-1. However, BPL is disappointed that GLHA, as stated in the Recreation Study Plan, Section 10.0 - Deviations from Requested Study, is not proposing to similarly assess boat access to the North Twin Impoundment and Millinocket Lake as BPL also requested. GLHA's justification for this determination is "they are held close to full pond level throughout the normal recreation season."

Based on the data GLHA has provided to-date within the ILP, we are not able to discern the accuracy of this statement and thus the validity of the justification to not conduct the requested study. We therefore remain reliant on the FERC-permitted drawdown limits (10 feet at Millinocket Lake year-round; 3.5 ft drawdown at North Twin until October 15). Note also that the Bureau is interested in verifying boat access on these water bodies through the ice-free season (generally May through November), six weeks beyond the end of the North Twin drawdown limit and perhaps beyond the undefined "normal recreation season" cited by GLHA. Due to the lack of operational data and the lack of data on the range of impoundment levels that each boat access facility is fully functional, as mentioned in our study request, public boat access to these water bodies through the ice-free season remains unverified.

In closing, the Bureau reiterates the importance that the ILP ensure public access to North Twin impoundment and Millinocket Lake throughout the ice-free season.

*Assessment of Boat Access to the "Back Channel" (Penobscot Mills Project)*

In response to requests from the Maine Department of Inland Fisheries and Wildlife (MDIFW) and other stakeholders, GLHA has proposed to conduct a Back Channel Instream Flow and Habitat Assessment Study. As described in the Study Plan, provided in PSP Appendix B, the methodology of the study includes evaluation of flows in the range of 3 to 2,000 cfs. Although the purpose of the study is to evaluate a minimum flow regime most suitable to establish a seasonal put-and-take adult brook trout fishery, the potential exists for such flows to also provide

a recreational boating opportunity on the Back Channel. Under the current license, Back Channel flows are limited to spillage from Stone Dam at most times, therefore no boating opportunity exists.

BPL requests, in the event that the Back Channel Instream Flow and Habitat Assessment Study results in boatable flows on the Back Channel, that the Recreation Study include:

- assessment of public road access to the channel (presumably, access to a newly established fishery would also be required; therefore, this request may coincide with fishery-related requests and not require additional effort);
- assessment of potential put-in and take-out locations on the channel for paddle-craft, and
- assessment of a portage route around Great Falls.

1.2.2 GLHA's Proposed Study Plan – Aesthetics Study and Recreation Study (Aesthetic Component)

GLHA has not adopted the Aesthetic Resources Study requested by American Whitewater (AW) and Appalachian Mountain Club (AMC), as recorded in PSP Table 1-1, page 1-21. The justification given is the lack of a substantiated problem with substantial light or glare, and the lack of adverse aesthetic impacts of Project infrastructure in their remote and largely undeveloped setting. However, these justifications do not address the aesthetic impact of impoundment drawdown, in particular at the Ripogenus Impoundment (Chesuncook Lake).

AW and AMC also requested that an aesthetic assessment be included as a component of the Recreation Study. GLHA has not adopted the aesthetic component, with the justification that it is overly expansive in both geographic and regulatory scope.

However, FERC, in Scoping Document 2 (SD2, released November 22, 2021), section 4.1.5 Recreation, Land Use, and Aesthetics, in response to numerous stakeholder comments identifies the following resource issue to be analyzed in the NEPA document:

- Effects of continuing to operate and maintain the Projects, including the effects of the drawdowns and low lake levels, on aesthetic resources in the Projects' areas.

Concerns about adverse effects of drawdown on aesthetic resources at Chesuncook Lake, as well as boat navigation and water access to camps and public campsites, has been substantiated by comments from Chesuncook Lake campowners and others (see PSP Appendix I, comments submitted by J. Lepage, 9/28/21; L. Paone, 9/29/21; K. Houston, 10/2/21; O. Genest, 10/5/21; and others). In light of the above, BPL requests that an analysis of the effects of drawdown and low lake levels on aesthetic resources at Chesuncook Lake be incorporated into the Recreation Study. This analysis should address views of the lake and surroundings from FERC-approved recreation sites (as GLHA intends to do as described in the Recreation Study, page F-11) as well as from the lake surface by boaters.

Requested Operations Data

In PSP Appendix J, page 2, GLHA states in response to requests from BPL and others that 10 years of operations data "will be provided with the RSP or before". It is our belief that this data

should be provided well before the RSP is submitted, because it is essential in determining study needs for the ILP.

Thank you for the opportunity to submit these comments. Please feel free to contact me at (207) 287-2163 or via email at Jim.Vogel@maine.gov if you have any questions regarding these comments and study requests.

Sincerely,

James Vogel, FERC Coordinator

**Re: MDIFW Comments on the Proposed Study Plan for the Ripogenus Hydroelectric Project (FERC No. 2572) and Penobscot Mills Hydroelectric Project (FERC No. 2458)**

Dear Secretary Bose:

On November 23, 2021, Great Lakes Hydro America, LLC (GLHA), a subsidiary of Brookfield Renewable (Brookfield, Licensee), submitted their Proposed Study Plan (PSP) for both the Ripogenus Hydroelectric Project (FERC No. 2572) and Penobscot Mills Hydroelectric Project (FERC No. 2458). The Projects are located on the West Branch of the Penobscot River and Millinocket Stream, and span both Piscataquis and Penobscot Counties, Maine.

On December 15 and 16, 2021, GLHA held their PSP meeting, which MDIFW staff attended. GLHA reached out to MDIFW regarding several of our Agency's wildlife Study Requests and subsequently hosted a virtual meeting with MDIFW staff on February 9, 2022. We appreciate the Licensee's willingness to confer with MDIFW regarding our proposed wildlife studies in addition to the PSP meetings, and MDIFW and GLHA have made some important strides in resolving some of the disparities between our original wildlife Study Requests and the PSP. However, we remain concerned that the requested operational data for these Projects are still not available, and the perceived changes in Project operations from when the Millinocket and East Millinocket Mills were operational are currently making it difficult to adequately assess environmental impacts during this relicensing period.

*Except as described below*, we respectfully request that FERC adopt the study and information requests made in our MDIFW Comments and Study Requests filed on October 8, 2021. To be clear, our Agency is utilizing this limited period of time between 30- to 50-year Federal licenses to become better informed on how current Project operations are affecting inland fisheries and wildlife resources and their respective habitats in the Project areas. MDIFW believes that the only way to better understand these complex interactions is through the Study Requests we have proposed.

PHONE: (207) 287-5254 FISH AND WILDLIFE ON THE WEB: www.maine.gov/ifw EMAIL ADDRESS: IFWEnvironmentalreview@maine.gov

## Section 3 Requested Studies Not Adopted

In their PSP, multiple study requests were not adopted by GLHA, including several wildlife studies recommended by MDIFW. Subsequent to the December PSP meetings, however, GLHA met virtually with MDIFW to discuss alternatives to the proposed wildlife studies. Our comments below reflect our understanding of the current status of each study.

So that MDIFW can be kept abreast of the ongoing field efforts for these significant, complicated, and extremely remote Projects, MDIFW is willing to partner with GHLA in some of the wildlife surveys, as staff time allows and with adequate notification and planning.

### 3.13 Study to Assess Presence of Wood Turtles and Project Effects on Nesting Habitat, Nesting Success, and Overwintering Habitat

MDIFW requested a study to assess the presence of wood turtles and Project effects on their nesting habitat, nesting success, and overwintering habitat.

Current status: This study request was originally denied in GLHA's PSP. However, as discussed during the February 9 virtual meeting between GLHA and MDIFW, it is our understanding that GLHA will contact MDIFW's reptile expert to discuss suitable survey locations, based off aerial imagery interpretation. Onsite assessments of these survey locations will consist of documentation of available wood turtle nesting habitat along with a description of the habitat relative to the West Branch of the Penobscot River and surrounding environs within the floodplain. Suitable overwintering habitat will be similarly recorded. GLHA will also assess how the magnitude and timing of flow releases may be affecting these habitats, both through field measurements and information gleaned from the Historical Operations Data and Assessment Study. Any wood turtles that are observed will be documented, their location recorded via GPS, sexed, aged, photographed, and be marked by shell notching using the Ernst et al. (1974) scheme. This information will be reported to MDIFW at the end of the season, including a discussion on the effects of Project operations on these resources and nesting success. The results of this Phase 1 Study may necessitate a more robust Phase 2 Study, including the use of telemetry. These study details, including methodology, goals, and anticipated reporting requirements, should be clearly explained in the Revised Study Plan.

### 3.14 Marsh Bird Surveys

MDIFW requested a Marsh Bird Survey to determine if any rare marsh-nesting birds (least bittern, sedge wren, black tern, common gallinule, or American coot) occur in the Ripogenus and Penobscot Mills Project areas, and if operations of the Projects are potentially affecting their productivity.

Current status: This study request was originally denied in GLHA's PSP. However, as discussed during the February 9 virtual meeting between GLHA and MDIFW, it is our understanding that GLHA will contact MDIFW's marsh bird expert, who will provide any existing data as well as discuss suitable survey locations, based off aerial imagery interpretation, in support of GLHA conducting a marsh bird survey in a subset of wetlands within the

boundaries of the Projects. Surveys will follow approved MDIFW marsh bird survey methodology. This information will be reported to MDIFW at the end of the season, including a discussion on the effects of Project operations on these resources. These study details, including methodology, goals, and anticipated reporting requirements, should be clearly explained in the Revised Study Plan.

**3.15 Furbearer Survey**

MDIFW requested a Furbearer Survey at the Ripogenus impoundment to assess the relative abundance of muskrats and beavers by comparing their abundance with a natural reference (control) location of comparable size and shoreline characteristics (wetlands), and to 1) assess muskrat food availability throughout the year, 2) determine overwinter survival and cause-specific mortality rates of muskrats and beavers, 3) measure hydrology characteristics (water flows and depths) in areas of suitable habitat, and 4) determine use and movements of muskrats and beavers.

Current status: This study request was originally denied in GLHA's PSP. However, as discussed during the February 9 virtual meeting between GLHA and MDIFW, it is our understanding that GLHA will document muskrat and beaver activity, including the locations of any houses, lodges, and caches, during the course of the 2022 field season, including into the late fall season. All muskrat and beaver activity will be documented via GPS and photographs, with a description of their status (i.e., active, inactive, abandoned, etc.) as well as their location relative to changing water levels during the course of the season. This information will be reported to MDIFW at the end of the season, including a discussion on the effects of Project operations on these resources. These study details, including methodology, goals, and anticipated reporting requirements, should be clearly explained in the Revised Study Plan.

**3.17 Common Loon Productivity Assessment**

MDIFW requested a Common Loon Productivity Assessment for the Millinocket Lake Storage Impoundment and the North Twin Impoundment to evaluate common loon nesting success, determine if operations of the Project are affecting loon productivity, and assess causes of nest failure to determine if these failures are influenced by Project operations.

Current status: This study request was originally denied in GLHA's PSP. However, as discussed during the February 9 virtual meeting between GLHA and MDIFW, MDIFW reiterated our need for clarification regarding actual headpond water level fluctuations during the common loon breeding season (May 15 – July 31). As described in the PAD:

- Millinocket Lake: current and proposed Project operations maintain the Millinocket Lake reservoir level between elevations 470 and 480 feet at the Millinocket Lake Storage Development while providing water to maintain North Twin impoundment levels.
- North Twin: the Licensee maintains the North Twin impoundment at a relatively stable level from May 1 - August 22 annually ("relatively stable level" is not defined).

GLHA stated that they understood our confusion and will assess annual historic water levels at both Millinocket Lake and North Twin Impoundment during the loon breeding season using information gleaned from the Historical Operations Data and Assessment Study. Any deviations from 0.5 vertical feet up or 1 vertical foot down occurring within a 28-day period during the loon nesting season (May 15 – July 31) will be reported to MDIFW, including a discussion on the effects of Project operations on common loon productivity at these locations. These study details, including methodology, goals, and anticipated reporting requirements, should be clearly explained in the Revised Study Plan.

**3.18 Common Loon Management Plan Assessment**

MDIFW requested a Common Loon Management Plan Assessment for the Ripogenus Project to evaluate the existing Common Loon Management Plan for the Ripogenus Project. The goals of the study would be to assess use of the artificial nest platforms deployed at the Ripogenus impoundment, evaluate loon productivity, and determine if Project operations, particularly during low water years, are impacting loon productivity and if new strategies need to be incorporated.

Current status: This study request was originally denied in GLHA's PSP. However, as discussed during the February 9 virtual meeting between GLHA and MDIFW, MDIFW is requesting additional information on the existing Plan for the Design and Implementation of Artificial Nesting Structures for Common Loons, including but not limited to how well the Plan has been adhered to; annual maintenance and deployment of nesting structures; the status of rafts during periods of drawdowns; and how frequently raft locations are adjusted during drawdown periods. GLHA will investigate and provide this information to MDIFW, at which time an assessment of the effectiveness or need to revisit the Plan will be determined. The goals and anticipated outcome of these investigations should be clearly explained in the Revised Study Plan.

**Appendix B: Back Channel Instream Flow and Habitat Assessment Study Plan**

Regarding the West Branch below Stone Dam ("Back Channel") Instream Flow and Habitat Assessment Study Plan, MDIFW requests that in addition to brook trout, the species list be expanded to include landlocked salmon habitat.

**Appendix C: North Twin Impoundment Tributary Access Survey Study Plan**

As detailed in Table 1-1, the Licensee adopted this study request, but with modifications. However, the significant modifications being proposed do not include the MDIFW requested radio telemetry study to track salmonid movement, in part, because:

*"GLHA believes that radio telemetry is not the appropriate methodology to evaluate tributary access for landlocked salmon."*

Instead, GLHA proposes the North Twin Impoundment Tributary Access Study Plan. MDIFW supports this new study proposal with the following goals and objectives:

- *"Identify tributaries to the North Twin impoundment that are used by landlocked salmon for spawning or that have habitat suitable for spawning;*

- *Survey the identified tributary streams and identify potential fish passage barriers both natural and Project-related near their confluence with the North Twin impoundment; and*

- *Evaluate the effects of the typical seasonal impoundment fluctuation on tributary access by landlocked salmon during critical life stages."*

However, the proposed North Twin Impoundment Tributary Access Study Plan does not address the management focus of the initial MDIFW proposed Comprehensive Impoundment Landlocked Salmon Habitat Use/Spawning Study, including several goals and objectives:

- *Track seasonal movements and behaviors of landlocked salmon (within and between the five connected lakes) via radio telemetry;*

- *Determine the effects of annual Project drawdowns on the movement and behaviors of landlocked salmon within the North Twin impoundment; and*

- *Identify landlocked salmon spawning areas within the North Twin impoundment.*

As previously indicated in the PSP, landlocked salmon were historically stocked periodically in the North Twin impoundment by MDIFW for 17 of the 36 years between 1937 and 1973, then annually from 1976 to 2010, and 2014-2017. A continuously decreasing number of landlocked salmon were stocked during the 2014-2017 timeframe. Stocking of landlocked salmon ended in 2017 after MDIFW gill net surveys at the time indicated a large percentage of captured salmon were of naturally reared origin. Presently, landlocked salmon in the North Twin impoundment consist of a self-sustaining naturally reproducing population relying on adequate and accessible spawning habitats. The Department is continuously striving to improve the landlocked salmon fishery to a healthy balance, and with that maintain an equally healthy population of rainbow smelt, the primary prey species of landlocked salmon. As outlined in the PAD, under the current operating license issued in 1996, Article 408 required GLHA to maintain the North Twin impoundment at a minimum target level of 488.42 feet for the period August 22 through October 15 to accommodate lake trout spawning and incubation in October. However, after periodic lake trout monitoring during the early 2000's it was determined wild lake trout reproduction was not occurring in the impoundment. Therefore, Article 408 was amended in 2012 to remove the minimum target lake elevation level during the period August 22 through October 15. With the minimum target lake elevation now removed, MDIFW believes that the Project's seasonal drawdown cycles could have a negative impact on wild landlocked salmon movement, spawning, and incubation within the impoundment and its tributaries.

MDIFW fisheries management objectives have changed in the North Twin impoundment since the last relicensing of Penobscot Mills. Where historically the landlocked salmon fishery relied on annual stocking of hatchery-reared fish, presently (since 2018) the salmon population has

consisted of 100% naturally reared landlocked salmon. In the past, when the focus was on Project operation effects as they related to attempting to establish a naturally reared lake trout population, little thought was given to location, timing, or even success of landlocked salmon spawning since the fishery was of stocked origin. Today, there is virtually no information on what effects Project operations and seasonal water level fluctuations may have on landlocked salmon life histories, most importantly spawning and rearing potential. Tracking landlocked salmon movements through the use of radio telemetry within the North Twin impoundment will help document potential effects of Project operations on spawning behavior as well as help document timing and spawning locations of naturally reared salmon.

**Comment on Diadromous Species**

Any planned reintroduction of diadromous species into the Penobscot Mills Project should be coordinated with MDIFW based on the outcomes of discussions and research being undertaken within the joint Federal and State partnership of the Alewife Interaction Committee to reach a balanced approach to comanaging resident inland and diadromous species in this and other waters around the State. Density-dependent interactions between anadromous alewives and managed inland fisheries remain an ongoing concern of our Agency. Additional concerns relate to preventing invasive species from being introduced above said licensed Project in the advancement of diadromous fish restoration. We believe there are options that would support both restoration of diadromous species and prevent the spread of invasives at the Penobscot Mills Project. We want to clarify that MDIFW remains committed to working with our State and Federal partners on studying restoration of diadromous species at the Penobscot Mills Project should fish passage be considered during the term of the new license, and MDIFW should be party to any future discussions pertaining to fish passage. Therefore, our comments should not be interpreted as conflicting with the other State and Federal resource agencies that are stakeholders to this relicensing.

The natural resources and other concerns associated with these Projects are very complex, and we appreciate the Licensee's ongoing commitment to work through these issues. We also look forward to our review of the Revised Study Plan as well as partnering with GLHA with any studies as our staff time allows. Please feel free to contact my office if you have any questions regarding this information, or if I can be of any further assistance.

Best regards,

John Perry
Environmental Review Coordinator

**RE: Proposed Study Plan Comments for the Ripogenus (FERC No. 2572-133) and Penobscot Mills (FERC No. 2458-247) Hydroelectric Projects**

Dear Secretary Bose:

The Maine Department of Marine Resources (MDMR) is writing in response to the Proposed Study Plan (PSP), dated November 23, 2021, for the Ripogenus and Penobscot Mills Hydroelectric Projects (collectively referred to as Projects), located on the West Branch of the Penobscot River and Millinocket Stream in Piscataquis and Penobscot Counties, Maine. The projects are operated by Great Lakes Hydro America, LLC (GLHA; Applicant). GLHA held virtual meetings to discuss the PSP and solicit feedback from stakeholders on December 15, 2021 and December 16, 2021. The comments of MDMR are provided in the following document.

Please contact Casey Clark at casey.clark@maine.gov or at 207-624-6594 if you have any questions.

Sincerely,

Patrick C. Keliher, Commissioner

## General

On October 8, 2021, the Federal Energy Regulatory Commission (Commission; FERC) issued an Additional Information Request for detailed operations data needed to clarify how the projects are operated on a daily basis. Specifically, the Commission requested GLHA include as an appendix to the Proposed Study Plan, 10 years of operations data (in excel format) for each project, or each individual development, in the case of the Penobscot Mills Project, including: (1) daily impoundment elevations; and (2) daily outflows (minimum, maximum, and average discharges). This request is consistent with the information requested by several stakeholders in comments on the Pre-Application Document (PAD) and study requests for Projects. MDMR supports this as a request for additional information that is critical for project scoping. Given that this is data that is readily available to GLHA, MDMR requests that the data be provided to stakeholders within 14 days of this letter.

In the PSP, GLHA states, "GLHA is proposing the studies that meets the criteria and are believed to be required for FERC to perform its environmental analysis for MDEP to issue the Projects' Section 401 Water Quality Certificates, and for FERC to develop the license requirements under which the Projects will operate for the term of the Projects' New Licenses." In our study requests, MDMR included only studies that have been approved by the Commission during relicensing at similar projects in Maine and other New England states. Thus, these studies have been determined by the Commission to be required to inform the Commission's development and analysis in their NEPA document for environmental analysis and for MDEP to issue the Projects' Section 401 Water Quality Certificates. If the studies that MDMR proposed are not performed as requested during relicensing, it is our determination there will be significant gaps in information and the Applicant will not be able to prepare a complete and adequate Draft License Application.

In our October 12, 2021 PAD comments and study requests[1] MDMR requested the following six studies:

1. Three-Dimensional Computational Fluid Dynamics (CFD) Modeling Upstream and Downstream of the Discharge and in the Vicinity of Powerhouse Forebays
2. Upstream Juvenile Eel Assessment
3. Downstream American Eel Passage Assessment
4. Downstream Passage Alternatives Study
5. Upstream Passage Alternatives Study
6. Evaluation of the Size of American Eels and the Timing of their Downstream Migratory Movements

A recuring theme in the PSP was an inaccurate interpretation of the comments filed by Maine Department of Inland Fisheries and Wildlife (MDIFW) on October 8, 2021.[2] GLHP states, "The Ripogenus and Penobscot Mills Projects are located on the West Branch, and Project waters are currently managed by MDIFW as a resident coldwater sport fishery for landlocked salmon and brook trout. MDIFW has stated that it wants no change to the current upstream fish passage at the Projects to combat the continued spread of invasive species, which are a serious threat to Maine's wild and native

[1] Accession Number: 20211012-5681
[2] Accession Number: 20211008-5293

fisheries. As a result, there are no current plans to create fish passage for anadromous species at the Projects." This conclusion is an intentional misinterpretation of the statements of MDIFW, which MDIFW clarified at the PSP meetings on December 15, 2021 and December 16, 2021.

The 2009 comprehensive management plan states, "American eel, American shad, and Atlantic salmon historically utilized portions of the West Branch Penobscot, but the 10 hydropower and water storage dams on the West Branch Penobscot do not pass diadromous fish and no passage is planned in the near term."[3] While the historic habitat for these species and alewife was identified in the plan, no passaged was planned and no passage measures were supported by the licensee for the Projects. Therefore, there was no path at the time of writing of the 2009 comprehensive plan for restoration of diadromous species to the habitat in the West Branch Penobscot. The absence of upstream passage facilities at the Projects prevents upstream passage for most diadromous species, including sea-lamprey not explicitly mentioned in the plan, and inhibits the passage of American eels. In addition, the lack of downstream passage facilities at the Projects likely have impacts on the survival and injury of American eel and would likely have impacts on other diadromous species.[4] As the Projects are currently undergoing relicensing, MDMR has submitted study requests that will adequately evaluate the effects of the Projects on resources of concern and provide the critical information needed to develop license conditions; including fish passage facilities.

In addition, the comments and study requests of MDMR should not be interpreted as in conflict with the invasive species concerns expressed in MDIFW's comments. Invasive species control will need be a primary goal for the continued operation of the Projects and maintenance of the Project impoundments regardless of fish passage structures at the Projects. While the Project Facilities have created large impoundments that provide foraging habitat for landlocked salmon, impoundments like these are well documented as facilitating the spread of invasive species into the impoundments themselves as well as into connected natural lakes.[5] This invasive species spread includes both flora and fauna. The most common pathway of spread of invasive species is not through fishways but from recreational boat bilges and the most effective approach to prevent invasive species spread is sustained outreach and education.[6] If supported by MDIFW, MDMR would recommend the Projects' licenses include annual support for outreach and monitoring at recreational facilities to prevent the spread of invasive species. Additionally, invasive species control is a common component of operation of fishways. In fact, BREG in their final license application for the Mattaceunk Project (P-2520) stated, "The fishway (with the supplemental attraction water) is typically operated from May through mid-November, and it is voluntarily monitored (through use of the fish trap) on a daily basis for successful Atlantic salmon passage and *to ensure that undesirable species (such as northern pike) are not passed upstream*." (Emphasis added). Similar measures would be expected for any fishways at the Projects to ensure invasive species are not passed upstream into the West Branch Penobscot.

**Requested Studies Not Adopted**

*Three-Dimensional Computational Fluid Dynamics (CFD) Modeling Upstream and Downstream of the Discharge and in the Vicinity of Powerhouse Forebays*

MDMR is amenable to delaying this study but disagrees with the timeframe assertions made by GLHA. American eels are present in the West Branch today and will pass the projects each and every season. Defining the specific impacts to eels during their migrations is the explicit purpose of our other study requests. This CFD study would add detail to project specific conditions (I.e. flow velocities in the vicinity of Project facilities) and aide in identifying project areas that likely have impacts (E.g. potential for impingement, potential route of passage based on flow velocities, etc.). In addition, this CFD study would provide information that will be necessary in the development of mitigation measures.

The FERC ILP process specifically outlines the timeline for completion of studies to inform relicensing of projects. GLHA did not include any description of "potential changes in operations or infrastructure, which could occur at one of more of the Projects' developments over the next 15 years" in the PAD. If any such developments are proposed as part of the relicensing process, this study should be delayed incorporating changes at the project, but it should still be completed in time to be available to resources agencies and FERC during their review of the draft license. Any changes to the Projects that take place outside of relicensing would be part of proposed amendments to any future license and should be viewed as separate from this relicensing process with separate review and study requirements.

Pursuant to the National Environmental Policy Act (NEPA) of 1969, as amended, Commission staff will prepare an environmental document (NEPA document) which will be used by the Commission to determine whether, and under what conditions, to issue a new license for the Projects. This study request will provide critical information to support and assist the Commission in their environmental review in the NEPA document of the following issues identified in section 4.1.2 Water and Aquatic Resources of Scoping Document 2 (SD2)[7]:

- "Effects of continuing to operate the Projects on aquatic (littoral) habitat for resident and migratory fish and freshwater mussel species (as appropriate) in the project impoundments and project-affected reaches downstream from project dams and powerhouses (e.g., the Upper Gorge, Holbrook Side Channel, West Branch downstream from Stone Dam, and Millinocket Stream)."
- "Effects of project flow diversion and dewatering of the river channel downstream from Ripogenus Dam and Stone Dam on fish populations and movement, aquatic habitat, and river connectivity."
- "Effects of continuing to operate the Projects on upstream and downstream passage of American eels in the West Branch."
- "Effects of continuing to operate the Projects on the movement of sea-run Atlantic salmon and alosines (American shad and river herring) in the West Branch and mainstem Penobscot River."
- "Effects of continuing to operate the Projects on fish impingement, entrainment, and survival at the Projects' developments."

[7] Accession Number: 20211122-3054

- "Effects of continuing to operate the Projects on state-protected aquatic species (e.g., brook floater, yellow lampmussel, and tidewater mucket).[8]"

In addition, this study request will provide critical supporting information to the following issues identified in section 4.1.4 Threatened and Endangered Species of SD2:

- "Effects of continuing to operate and maintain the Projects on: (1) the federally threatened Canada lynx and its designated habitat and northern long-eared bat; and (2) the federally endangered Gulf of Maine Distinct Population Segment Atlantic salmon and its designated critical habitat, including movement, restoration/recovery, and passage."

*Evaluation of the Size of American Eels and the Timing of their Downstream Migratory Movements*

As GLHA stated in the PSP, "Since neither of the two study methodologies outlined above are suitable for the Projects, and since there is already existing information on eel size and timing of out-migration in Maine, GLHA proposes to rely on the existing knowledge base of the timing and sizes of adult eels during downstream migration."

MDMR requests the Commission approve this study as submitted in our October 12, 2021 PAD comments and study requests. The two sources that GLHA references do not provide recent data, un-biased by fishing gear and effort, and inclusive of higher watershed projects. Shepard (2015) does not assess eel migration timing upstream of the West Enfield Project and thus the migration window will need to be modified to adequately project eels migrating from higher watershed projects. Migration must start earlier at projects higher in the watershed to allow time for eels to reach the lower watershed projects, where timing has been documented. As no information has been collected at projects this high in any watersheds in Maine for the purpose of documenting the eel migration window, we have no information to inform how early in the season eels begin their downstream migration or late they continue to into the winter.

In addition, there has been substantial change in conditions since the data used in Shepard (2015) and Haro (2003). The data utilized for both papers was collected prior to the Penobscot Restoration Project, which saw the removal to two dams on the lower river. The Penobscot Restoration Project also saw increasing of flashboard heights and implementation of fish passage measures at several projects including eel fishways. Those eel fishways would affect both the timing and abundance of yellow eels as they migrate upstream. The best available count of the upstream migration of eels after the Penobscot Restoration Project is at the West Enfield Project. Counts of juvenile eels at the West Enfield Project increased from 28 in 2012 to 218,755 in 2020.[9] This information is critical as it will be used to define the timing of protection and mitigation measures for adult eels.

[8] The Maine State Wildlife Action plan identifies: American Eel as Special Concern Species and Tier 2 priority Species of Greatest Conservation Need; Blueback Herring, American Shad, and Atlantic Salmon as Tier 1 priority Species of Greatest Conservation Need; Alewife as Tier 2 Species of Greatest Conservation Need.

[9] Accession Number: 20210401-5539; In addition, thousands of juvenile eels are also known to use the vertical slot fishway at the West Enfield Project in given year but are not included in the estimate.

OFFICES AT 32 BLOSSOM LANE, MARQUARDT BUILDING, AUGUSTA, MAINE
http://www.Maine.gov/dmr
PHONE: (207) 624-6550 FAX: (207) 624-6024

GLHA also states that American eel are thought to occur in limited numbers due to the Project's relative location high in the watershed. This statement is intentionally misleading as it does not acknowledge that upstream migration is impacted heavily by the presence of dams in a watershed. On the contrary, Hitt et al. (2012) found that eel density in a headwater stream increased dramatically following dam removal. As is well documented by the counts of eels at West Enfield, eel specific upstream passage dramatically increased the number of eels migrating higher in the watershed. In addition, while eels have been caught incidental to sampling for other species, no studies have been carried out that target eels specifically, so the density of eels is not known at this time. MDMR requests that GLHA conduct the study as we requested.

GLHA also expressed their concern over the study methodologies but they should note that similar methodologies have been used at other hydroelectric projects in the Northeast. To further bolster the traditional field approach we requested in our October 12, 2021 filing, MDMR has developed an additional eDNA study component that will ensure that study efforts result in data that is reflective of the resource and can be used to address issues raised by the Commission. To that end, MDMR requests that GLHA carryout an eel eDNA study that would require collection of water samples at designated sites, agreed upon by the resource agencies, in the impoundment and tailwater of each dam within the Projects. Recent studies have identified eDNA as a very effective tool in eel assessment.[10] Water samples should be collected after dark, daily, for the duration of the downstream migration season. Additional samples should be taken at a reference site where adult eel presence is known and well documented. Finally, additional eDNA samples will need to be collected periodically outside of the adult eel migration season defined in Shepard (2015) at the designated sites. These out-of-season samples will inform background eel eDNA levels and will allow in-season samples to be compared against a benchmark for each sampling location. It is important to note that an eDNA approach would provide timing and abundance (relative, not population abundance) information, but would not document the size of eels. Therefore, we are not recommending eDNA as a standalone approach.

This information is critical as it will be used to define timing of type of protection and mitigation measures for downstream migrating adult eels. As indicated by GLHA in the PAD and at the PSP meeting, eels are present upstream of the Project facilities. None of the Project facilities currently have structures or operations to protect downstream migrating adult eels. This study, as requested and unmodified, will result in critical information that will be used to 1) assess any potential impacts to project operations; and 2) develop adequate protection measures.

Pursuant to the NEPA of 1969, as amended, Commission staff will prepare a NEPA document which will be used by the Commission to determine whether, and under what conditions, to issue a new license for the Projects. This study request will provide critical information to support and assist the Commission in their environmental review in the NEPA document of the following issues identified in section 4.1.2 Water and Aquatic Resources of SD2:

- "Effects of continuing to operate the Projects on aquatic (littoral) habitat for resident and migratory fish and freshwater mussel species (as appropriate) in the project impoundments and

[10] Itakura et al. (2019); Cardás et al. (2019); Chin et al (2021)

project-affected reaches downstream from project dams and powerhouses (e.g., the Upper Gorge, Holbrook Side Channel, West Branch downstream from Stone Dam, and Millinocket Stream)."

- "Effects of project flow diversion and dewatering of the river channel downstream from Ripogenus Dam and Stone Dam on fish populations and movement, aquatic habitat, and river connectivity."
- "Effects of continuing to operate the Projects on upstream and downstream passage of American eels in the West Branch."
- "Effects of continuing to operate the Projects on the movement of sea-run Atlantic salmon and alosines (American shad and river herring) in the West Branch and mainstem Penobscot River."
- "Effects of continuing to operate the Projects on fish impingement, entrainment, and survival at the Projects' developments."
- "Effects of continuing to operate the Projects on state-protected aquatic species (e.g., brook floater, yellow lampmussel, and tidewater mucket).[11]"

*Downstream Passage Alternatives Study*

Note, GLHA separated the study request of MDMR for Downstream Passage alternatives into two study requests in the PSP, one for American Eels and a second for all other diadromous species, and rejected both. GLHA includes many false statements and conclusions in their rejection of these studies, which GLHA included in the rejection of other studies requested by MDMR. Please refer to our general comments in this filing for corrections of these false statements and conclusions. Regarding the Downstream Passage Alternatives Study, MDMR provides no additional comments.

*Upstream Passage Alternatives Study*

GLHA includes many false statements and conclusions in their rejection of these studies, which GLHA included in the rejection of other studies requested by MDMR. Please refer to our general comments in this filing for corrections of these false statements and conclusions. Regarding the Upstream Passage Alternatives Study, MDMR provides no additional comments.

**Study Requests Adopted With Modification**

*Upstream Juvenile Eel Assessment*

MDMR requests the Commission approve this study as submitted in our October 12, 2021 PAD comments and study requests. GLHA proposes in the PSP to conduct the study at the East Millinocket development, but not conduct the study at the remaining Projects' developments. In addition, GLHA has modified the goal of the study to, "assess **whether** American eel are found in or near the East Millinocket tailwater area, congregate at or near the base of the East Millinocket dam, or attempt to migrate upstream over the East Millinocket dam. GLHA will collect information regarding the timing of

[11] The Maine State Wildlife Action plan identifies: American Eel as Special Concern Species and Tier 2 priority Species of Greatest Conservation Need; Blueback Herring, American Shad, and Atlantic Salmon as Tier 1 priority Species of Greatest Conservation Need; Alewife as Tier 2 Species of Greatest Conservation Need.

movements, behavior, and the approximate size of juvenile American eel if they are present at the East Millinocket development."

As indicated in the PAD, "American eel have been found in each of the Project impoundments." In fact, American eel were documented as part of the fish assemblage catches from the previous relicensing of the Project.[12] Dams, such as East Millinocket Development, Dolby Development, Millinocket Development, North Twin Development, Millinocket Lake Storage Development, and the Ripogenus dam, are known to impair migration success for catadromous species such as American eel.[13] However, in the intervening years there have been no upstream or downstream passage facilities or operational measures installed or implemented at any of the Project facilities.

As noted in the 2009 Strategic Plan[14], the first project in Maine with a fish passage requirement for American eel was the Medway Project. The Medway Project (P-2666) is the first dam on the West Branch Penobscot. At the time of writing, the 2009 Strategic Plan included the following text related to eel passage in the Penobscot River, "Construction of upstream eel passage and implementation of downstream passage measures at Penobscot River projects should enhance eel abundance in the Penobscot basin, and increase escapement of pre-spawning adults to the ocean."

As MDMR stated in our October 12, 2021 PAD comments and study requests, the goal of this study is to assess the locations for dedicated upstream passage for American eel. The study has two objectives:

1. Conduct systematic surveys of eel presence/abundance below the East Millinocket Development, Dolby Development, Millinocket Development, North Twin Development, Millinocket Lake Storage Development, and the Ripogenus dam to identify areas of concentration of eels staging in pools or attempting to ascend wetted structures that would potentially establish the most effective location to place upstream eel passage facilities.
2. Collect eels with temporary trap/pass devices at areas identified from surveys as potential location of eel concentrations to assess whether eels can be collected/passed in substantial numbers, and whether locations are viable sites for permanent eel trap/pass structures.

Pursuant to the NEPA of 1969, as amended, Commission staff will prepare a NEPA document which will be used by the Commission to determine whether, and under what conditions, to issue a new license for the Projects. This study request will provide critical information to support and assist the Commission in their environmental review in the NEPA document of the following issues identified in section 4.1.2 Water and Aquatic Resources of SD2:

- "Effects of continuing to operate the Projects on aquatic (littoral) habitat for resident and migratory fish and freshwater mussel species (as appropriate) in the project impoundments and project-affected reaches downstream from project dams and powerhouses (e.g., the Upper Gorge, Holbrook Side Channel, West Branch downstream from Stone Dam, and Millinocket Stream)."

[12] Federal Energy Regulatory Commission (FERC). 1996. Final Environmental Impact Statement Upper Penobscot River Basin Maine, Ripogenus Hydroelectric Project (FERC No. 2572) and Penobscot Mills Hydroelectric Project (FERC No. 2458). Federal Energy Regulatory Commission, Public Reference and Files Maintenance Branch, Washington, DC.
[13] ASMFC (2014)
[14] MDMR and MDIFW (2009)

- "Effects of project flow diversion and dewatering of the river channel downstream from Ripogenus Dam and Stone Dam on fish populations and movement, aquatic habitat, and river connectivity."
- "Effects of continuing to operate the Projects on upstream and downstream passage of American eels in the West Branch."
- "Effects of continuing to operate the Projects on the movement of sea-run Atlantic salmon and alosines (American shad and river herring) in the West Branch and mainstem Penobscot River."
- "Effects of continuing to operate the Projects on fish impingement, entrainment, and survival at the Projects' developments."
- "Effects of continuing to operate the Projects on state-protected aquatic species (e.g., brook floater, yellow lampmussel, and tidewater mucket).[15]"

Finally, MDMR disagrees with GLHA's statement, "Such passive measures have a low chance of being successful given the expected low density of juvenile American eel in the Project area." Passive methods that are applied in tandem with active survey methods compliment the active surveys, which by design sub-sample temporally and therefore have the potential to miss eels. The two types of assessment together represent a methodology that ensures appropriate temporal and geographic coverage. In contrast the methods proposed by GLHA, specifically electrofishing for one night in June and one night in August, are an inadequate approach that will likely not provide useful information for the licensing process.

At the PSP meeting, a member of the Commission asked about the effectiveness of using traps/pots as a sampling method for American eel. MDMR currently conducts a fishery independent life cycle survey covering glass, yellow, and silver eels each year.[16] This survey relies on the use of a ramp and pot capture system for glass and yellow eels migrating upstream and a separate pot only approach for yellow eels in a pond. This approach is similar to those described by Turner et al. (2018).

*Downstream American Eel Passage Assessment*

MDMR requests the Commission approve this study as submitted in our October 12, 2021 PAD comments and study requests. A desktop study approach is an inappropriate modification because a desktop study approach will only provide a minimum estimate of mortality and is highly reliant on project specific inputs. In the PSP GLHA states, "In lieu of conducting a large-scale, comprehensive field assessment, GLHA proposes to examine the question regarding potential effects of downstream passage on adult American eel at each of the Projects' developments through a desktop assessment." A desktop study approach will not provide any information about route of passage related to Protect operations, injury, delay, or cumulative impacts of passing the four dams and the Millinocket Development Gatehouse that comprise the Projects' facilities. The Applicant has not provided any information, and none is publicly available, to address these data gaps. In addition, a desktop study will

[15] The Maine State Wildlife Action plan identifies: American Eel as Special Concern Species and Tier 2 priority Species of Greatest Conservation Need; Blueback Herring, American Shad, and Atlantic Salmon as Tier 1 priority Species of Greatest Conservation Need; Alewife as Tier 2 Species of Greatest Conservation Need.
[16] ASMFC (2021)

not identify project specific infrastructure (E.g. weirs, gates, routes clogged with debris, etc.) with high impacts on American eels. Given that the project facilities have wide spaced trash racks and no fish guidance structures, we assume that most eels in the watershed pass the project dams through the turbines and have the potential to high injury and mortality rates by current operations and infrastructure at the project facilities. Some of the projects also have concrete curtains below their spillways, which could also injure or kill downstream migrating eels.

High survival for downstream migrating eels is critical for the species. Recent studies have shown that poor downstream passage can be detrimental to an eel population and serve as an ecological trap.[17] MDMR requests that GLHA perform the Downstream American Eel Passage Assessment as requested. This information is necessary to determine the effects of Project operations on the American eel within the West Branch Penobscot and the subsequent development of any terms and conditions for this licensing proceeding. In addition, Pursuant to the NEPA of 1969, as amended, Commission staff will prepare a NEPA document which will be used by the Commission to determine whether, and under what conditions, to issue a new license for the Projects. This study request will provide critical information to support and assist the Commission in their environmental review in the NEPA document of the following issues identified in section 4.1.2 Water and Aquatic Resources of SD2:

- "Effects of project flow diversion and dewatering of the river channel downstream from Ripogenus Dam and Stone Dam on fish populations and movement, aquatic habitat, and river connectivity."
- "Effects of continuing to operate the Projects on upstream and downstream passage of American eels in the West Branch."

If a Turbine Blade Strike Analysis (TBSA) is included as part of this assessment, MDMR requests that all inputs for the TBSA be reviewed and approved by MDMR and other resource stakeholders before the studies are performed.

**RE: Penobscot Mills (P-2458-247) and Ripogenus (P- 2572-133) Proposed Study Plan**

Dear Secretary Bose,

The Proposed Study Plan (PSP) for the Ripogenus Hydroelectric Project (FERC NO. 2572) and the Penobscot Mills Hydroelectric Project (FERC NO. 2458), drafted by Great Lakes Hydro America, LLC (licensee) on November 22, 2021 has been reviewed by the Penobscot Indian Nation (PIN). The PIN has been an active participant for these important relicensing events and looks forward to continued consultation with the Federal Energy Regulatory Commission (FERC) and the licensee for purposes of minimizing the negative social, economic and environmental impacts of these private projects on the public resources in the West Branch of the Penobscot River.

**Background:**

The Penobscot Nation has inhabited the Penobscot River, including the West and East Branches, from time immemorial. This is the Nation's aboriginal domain. The Nation has never ceded its related aboriginal title to the River and its branches in any treaty and Congress has never extinguished that aboriginal title**.** It is the Nation's position that the Ripogenus and the Penobscot Mills Projects, located on the West Branch of the Penobscot River, occupy federal lands, the Penobscot Reservation.

**Socioeconomics Study Request:**

The PIN drafted and submitted comments on the Pre-Application Document (PAD) on October 12th, 2021, complete with a Socioeconomics Study request. Within these comments, the PIN identified the significant data gaps in Section 5.1 of that document. The socioeconomic conditions in the region were not adequately addressed and large portions of the history of the projects, their integral role in the papermaking industry and the extreme changes to employment in the region since the last relicensing, were not addressed. Great Northern Paper, (GNP) former owner and builder of the dams, was not even mentioned in the PAD. The PIN provided much of this history in its' PAD comments and outlined the need for a more robust analysis of the socioeconomic conditions in the region and how the potential relicensing of these projects could affect the regional socioeconomic conditions. The PIN drafted a study request to meet this unmet need.

Scoping Document #2 (SD2), released by the FERC in November of 2021, outlines the information required to complete their analysis according to the National Environmental Policy Act of 1969 (NEPA document). In line with the Electric

Consumers Protection Act (ECPA) of 1986, the FERC is required to give equal consideration of both power and non-power uses of the resource, in this case, the West Branch of the Penobscot River. The NEPA requires that the FERC independently evaluate the social, economic and environmental effects of relicensing the projects as proposed and consider reasonable alternatives to the proposed actions. The FERC's Scoping process helps to determine the required level of analysis and satisfy the NEPA scoping requirements.

The licensee conducted a PSP Public meeting on December 12th, 2021. During that meeting, the licensee outlined its reasons for not adopting the Socioeconomic Study as proposed by the PIN. At that time, attorney Allison Economy, representing camp owners within the projects area, vocalized support for such a study and requested it include addressing the needs of the camp owners she represents. This sentiment was echoed by other Non-Governmental Organizations (NGO). ***Additionally, FERC Outdoor Recreation Planner, Dustin Wilson, expressed support for a robust socioeconomic study in order that FERC have complete information to conduct their NEPA analysis.***

The PIN has attached an updated Socioeconomics Study request to fulfill the needs of the FERC study proposal guidelines. The study request, complete with additions asked for by the licensee, is attached at the end of this document.

**The FERC's Additional Information Request (AIR)**

The FERC made an AIR on October 8th, 2021. The FERC letter states:

> "*Therefore, please include, as an appendix to the Proposed Study Plan, 10 years of operations data (in excel format) for each project, or each individual development, in the case of the Penobscot Mills Project, including: (1) daily impoundment elevations; and (2) daily outflows (minimum, maximum, and average discharges).*"

This request is similar to request made by numerous stakeholders during the Scoping process. The PIN requested the exact information in its letter dated September 13th, 2021. As stated by the FERC in their letter dated September 28th, 2021,

> "*Following the scoping meetings, several stakeholders filed letters requesting: (1) additional information from Great Lakes Hydro America (GLHA) and Commission staff; (2) an extension of time to file comments on the Preliminary Application Document (PAD) and study requests; and (3) an additional public scoping meeting. These stakeholders included the* ***National Marine Fisheries Service*** *(NMFS; September 13, 2021); the* ***U.S. Fish and Wildlife Service*** *(FWS; September 14, 2021); the* ***Penobscot Indian Nation*** *(PIN) and the Maine Council of Trout Unlimited (Maine Council TU), both on September 16, 2021; and the Maine* ***Department of Marine Resources*** *(Maine DMR) and* ***Maine Department of Inland Fisheries and Wildlife*** *(Maine DIFW), both on September 17, 2021*".

The FERC denied the extension requests in order to keep the relicensing on schedule, and submitted their AIR in order to ensure adherence to the proposed schedule. The FERC stated in their letter dated September 28th, 2021 that,

> "*Because the established milestones are designed to prevent undue delay in the relicensing process, and the timing of the field seasons would be negatively affected by a 90-day delay in the process, the stakeholders' request for a 90-day extension of time to file comments on the PAD and study requests is denied*".

To date, the licensee has only supplied **e**xcuses for why this information is not being made available to the FERC and stakeholders and stated in the PSP that the information would be gathered as part of a study, to be made available at the end of the first year of studies. The Historical Operations Data and Assessment Study Plan is proposed in the PSP to be completed in 2022, with the report being made available in April of 2023.

> "*GLHA proposes to perform this study in 2022, with study results provided in the Initial Study Report to be filed with FERC in April 2023*".

The PIN finds this schedule to be extremely problematic. The information requested by the agencies, numerous NGO stakeholders and the FERC is critical in understanding the operations and impact of such operations on the public resources of the West Branch of the Penobscot River.

The PIN is confused as to why this data is challenging to provide. As an operator of these facilities for over decade, operational data for past and present operations should be part of the normal management of these facilities by the licensee/operators. The narrative created by the licensee, where multiple contractors and licensee staff is incapable of assembling such data in a timely manner, is absurd and disrespectful to the process and the stakeholders. The PAD was filed in June of 2021. The licensee has had adequate time to assemble and distribute the required information.

The PIN respectfully requests that the FERC intervene in this process and amend the relicensing schedule to reflect the licensee's unwillingness to provide this essential, baseline information. The shifting of the information request into a Study Proposal is unacceptable to the PIN and is undermining the relicensing designed to include stakeholder input into the Scoping process. The PIN is confused as to how the Scoping process can be completed, when the most basic and necessary of information is still being withheld from all stakeholders, to include the FERC.

The PIN is hopeful that the FERC will demand this information be supplied to stakeholders immediately and that the intentional game of obfuscate and delay being practiced by the licensee can come to a much needed end.

**Comments on Studies Proposed in the PSP—**

1) The licensee identifies the accuracy of handheld YSI ProSolo dissolved oxygen meters that are being used for studies of trophic status. However, there is very little information provided about the continuous monitoring sondes that will be used for the downstream temperature and dissolved oxygen assessment work, other than indicating an Onset HOBO data logger (or similar) will be used.

   *The* licensee *should state the accuracy of the loggers that they will use to ensure that they meet Maine DEP's accuracy requirement of 0.2 mg/L.*

2) *We recommend that the DO/Temperature loggers be equipped with sensor wipers to prevent biofouling of the probe, which is likely to occur during the deployment periods*.

3) Table 3 of Appendix A-10 provides the detection limits for impoundment trophic sampling. The detection limits listed from the HETL laboratory for several parameters are higher than the required Maine DEP reporting level/detection limits.

   *The* licensee *should work with their selected laboratory or select a different laboratory that will provide them with detection limits that meet those of Maine DEP.*

4) *Based on PIN experiences at Dolby Pond, we believe that the licensee should use at least 2 sites within the Dolby Impoundment for the trophic status study. In addition to the site displayed on map in Figure 5 of Appendix A-25, immediately upstream of the Dolby Dam, the applicant should also sample in the deep hole located in the North East portion of the impoundment. Water quality conditions between these two deep water areas can vary substantially and both are affected by the operation of the Dolby Dam.*

5) PIN disagrees with the licensee's assertion that riverine aquatic habitat cross-sectional flow studies are not needed below the McKay Station, Millinocket powerhouse, Dolby Dam, or the East Millinocket dams.

   *These studies are indeed needed to demonstrate that the projects attain aquatic habitat for fish and aquatic life within these areas. While the licensee claims studying these areas is unnecessary, the PIN is unable to evaluate whether water quality standards will be attained without the information from conducting these studies.*

6) PIN disagrees with the licensee's decision to not adopt proposed studies by NMFS including 1) Study to Evaluate the Effects of Operating the Penobscot Mills and Ripogenus Dams on the Hydrology of the West Branch and Mainsteam Penobscot River Using Indicators of Hydrologic Alteration Model; 2) Study to Evaluate Project River Temperature in West Branch and Mainstem Penobscot River; 3) Study to Evaluate Future Flow and Water Temperature Scenarios.

   *The PIN believes that these are important studies that are needed to evaluate how the proposed operation of these dams affects the flows and water temperature within and downstream of the project areas. These large projects must be evaluated in the context of the watershed which they exist and effect.*

**USFWS comments on the PSP:**

The PIN would like to express its support and concurrence for the USFWS comments submitted on February 22, 2022. The PIN has worked collaboratively with the USFWS throughout this relicensing and will continue to support the goals of the USFWS for this important relicensing.

Please reach out at any time if there are questions or any clarification needed for these comments.

Sincerely,

Daniel McCaw

Fisheries Program Manager
Penobscot Indian Nation
Indian Island, Maine

**Appendix 1. Penobscot Indian Nations' Socioeconomics Study proposal**

**Socioeconomics Study**

*§5.9(b)(1) –* ***Describe the goals and objectives of each study proposal and the information to be obtained.***

The goals of the study would be to describe the existing socioeconomic environment in the study area, including population, housing, economic development, public services, local energy production, State of Maine statues for energy production in the future, fiscal conditions, and infrastructure. The effects of project relicensing on the local and regional socioeconomic conditions will need to be evaluated in order for the FERC to adequately understand project effects on local resources, to include water quality, fish and wildlife, cultural, recreation, aesthetics, land use, and tribal resources.

The study would describe socioeconomic resource trends under the existing condition, summarize the existing condition of the recreation resources in the study area and describe the current Project and social and environmental measures as they relate to the socioeconomic factors. The study should also include extensive input from stakeholders to determine the priorities for future use of the resources described previously.

The study would also describe changes in employment or income associated with modifications to recreational potential for the river in existing and no-dam conditions. The study would describe the current socioeconomic condition of the Maine Tribes and identify socioeconomic issues and concerns.

The study would also serve as a source of information in considering other options for the projects, to include altered operational regimes to better suit recreational activities such as fishing, guiding and whitewater rafting. License orders could be based on the needs of local stakeholders, as operation of the projects is no longer tied to the defunct papermaking industry for which the dams were first built and last relicensed. Decommissioning and removal of some or all of the projects, for instance, may better suit a local economy based on tourism and multiple uses.

To understand incremental Project effects on socioeconomic resources, it is important first to characterize the existing population demographics, local human resources and public services, the local and tribal economy, as well as pertinent trends in such factors. It will be necessary to identify the study area in terms of the geographic extent of the potential incremental Project's sphere of influence on the socioeconomic condition as well as to identify likely differences across regions in the types of socioeconomic factor effects. The existing information is used to identify current socioeconomic conditions and expected trends in the study area. This is one of many reasons a Working group should be established: to define these parameters for the study.

The results of this study will provide information to satisfy FERC license application requirements specific to Project-related effects on the socioeconomic environment as specified in the applicable sections of 18 CFR Parts 4 and 16.

*§5.9(b)(2) –* ***If applicable, explain the relevant resource management goals of the agencies or Indian tribes with jurisdiction over the resource to be studied.***

The PIN has concerns that the West Branch of the Penobscot River, a public resource of the highest value to the Tribe is being negatively impacted by the continued operation of the projects. Ecological integrity of the system is impossible in a river where the majority high-gradient habitat is flooded by the projects and the riverine stretches in between the projects are impaired by peaking operations. Traditional cultural practices are unable to be exercised because of the extreme modification and industrialization of this public resource called the West Branch of the Penobscot River. The PIN believes that a large scale, comprehensive socioeconomics study is needed to understand these issues and the effects of projects operations on these resources concerns. This information will be needed by the FERC in order complete their analysis of project effects and would inform the development of license conditions needed to protect and enhance resources identified by local stakeholders.

Specific issues of concerns for the PIN include:

a) Lack of fish passage and turbine exclusion measures for diadromous and native species in their historic range. Numerous species remain extirpated from the West Branch due to the lack of structures and are unavailable for Tribal sustenance and regional recreational opportunities.

b) Access to historically important sites for cultural and sustenance uses, many of which are unavailable due to the project impoundments and operations. Cultural and recreational opportunities are unavailable in the project areas due to the presence of the projects, their impoundments and peaking operations.

c) Recreational activities such as fishing, boating, camping, birding, and ecotourism, to name but a few, are greatly hindered by the projects and their operations. The local economy is negatively affected by the continued negative projects effects and no longer receive any positive gain from the projects. The local economy will be based on ecotourism and outdoor adventures as the region adapts to the loss of the GNP paper mills once powered by these projects.

d) The negative effects of peaking flow manipulation on the social, economic, cultural and recreational opportunities on the West Branch of the Penobscot River.

*§5.9(b)(3) –* ***If the requester is not a resource agency, explain any relevant public interest considerations in regard to the proposed study.***

The requestor is a Federally-Recognized Indian Tribe, the Penobscot Indian Nation.

*§5.9(b)(4) –* ***Describe the existing information concerning the subject of the study proposal, and the need for additional information.***

The PIN knows of no such study or data available, with the exception of the population and census data contained within the PAD. The current socioeconomic conditions of the region are dramatically different when compared to the last licensing period. The local papermaking mills have all been closed and the power from the projects does not support the entire region through its connection to the mills. The potential for multiple uses of the West Branch of the Penobscot River exists. Historically, the local community and the State of Maine government let the public resources of the West Branch of the Penobscot River be utilized for the benefit of the local mills which supported the entire local economy. The local communities no longer receive any public benefit from the projects and the needs of the local economies are no longer supported by the projects. However, no information exists on the cultural, economic and recreational activities that are affected by the projects, or the opportunities that could be realized if some or all of the projects were decommissioned and removed. Alternative operations and protective structures at the projects need to be evaluated against the local socioeconomic conditions and needs. The information gathered by an extensive socioeconomics study will be needed by the FERC to complete their analysis of project effects and will help determine future license conditions needed to protect and enhance the local socioeconomic conditions, if the projects are relicensed.

§5.9(b)(5) ***Explain any nexus between project operations and effects (direct, indirect, and/or cumulative) on the resource to be studied, and how the study results would inform the development of license requirements.***

The connections between the project, project operations and the socioeconomic conditions in the local region are extensive. The Great Northern Paper (GNP) Company was founded in the late 1800's. The company created the "Magic City" in the north Maine woods where no organized town had been before. GNP contracted for homes, tenements and even a hotel to be built in the city to supply housing for workers at the mills. (http://greatnorthernpaperhistory.com/the-paper-giant/millinocket-grows.html) GNP built and maintained the Penobscot Mills and Ripogenus projects specifically to provide energy to their mills and to provide an economic advantage over its competitors. It was the first paper mill to have an electrical generation and distribution facility built into the plant. (https://en.wikipedia.org/wiki/Great_Northern_Paper_Company) In the 1940's the timberland owned by GNP had grown to over 5 million acres. In 1977 GNP was still Maine's second largest private employer after Bath Iron Works. At one time GNP's was the nation's largest industrial hydro-electric system, producing enough power to electrify a city of 450,000 or, comparably, almost half the homes in Maine. (https://damnyankee.com/great-northern-paper)

The projects have multiple connections to the local socioeconomics. Cultural, outdoor and economic opportunities are linked to the management of the West Branch of the Penobscot River. The West Branch of the Penobscot River is highly modified by the projects and flows are managed in a peaking mode in order to maximize profits for the licensee. The River is affected by the projects and project operation not only in the projects areas, but also throughout the region and Penobscot River drainage. Fish populations are diminished to historically low numbers, riverine reaches have been flooded and highly managed for flows, and Tribal cultural traditions, to include sustenance fishing, are all negatively

impacted by the projects and project operations. Future license orders should be based on the extensive information this study will provide.

*§5.9(b)(6)* ***Explain how any proposed study methodology (including any preferred data collection and analysis techniques, or objectively quantified information, and a schedule including appropriate field season(s) and the duration) is consistent with generally accepted practice in the scientific community or, as appropriate, considers relevant tribal values and knowledge.***

There are many methodologies used by professionals and researchers to describe socioeconomic conditions in a region. Regional economic modelling can be accomplished using economic input-output models (i.e., IMPLAN, JEDI) or through computable general equilibrium (CGE) models.

IMPLAN is a proprietary software that is the industry standard for economic impact assessment and regional economic modeling. CGE is becoming more popular in academic literature. IMPLAN was originally developed and is now maintained by the Minnesota IMPLAN Group (MIG). It models monetary flows through major sectors of the specific region's economy through a set of extensive economic databases, region-specific multipliers (local, state, national), demographic statistics, and highly refined quantitative analysis. IMPLAN allows the user to develop local-level input-output models that can estimate the economic impact (local spending, jobs, tax revenue, etc.) of new firms moving into an area as well as the impacts of professional sports teams, recreation and tourism, and residential development. The model accomplishes this by identifying direct impacts by sector, then developing a set of indirect and induced impacts by sector through the use of industry-specific multipliers, local purchase coefficients, income-to-output ratios, and other factors and relationships. IMPLAN has been used by numerous entities, to include, the U.S. Dept. of Interior, the United States Fish and Wildlife service (USFWS), the State of Maine, and countless others.

The Jobs and Economic Development Impact (JEDI) models developed by the National Renewable Energy Laboratory (NREL) includes a freely available hydropower-specific economic impact model that uses a similar "input-output" modeling approach as IMPLAN but with hydropower-specific inputs and characteristics. In addition to these industry standards in economic impact assessment, other types of socio-economic modeling can be accomplished via hedonic pricing, contingent valuation, willingness-to-pay, and social cost of carbon studies that are very common in economic research and practice.

The PIN recommends a working group be formed to help identify the specific socio-economic parameters that should be included in the study (i.e., jobs, local spending, tax revenue, property values, greenhouse gas emissions reduction, etc.) and the specific methodologies most appropriate to each parameter. There are several professors of economics at the University of Maine who could help advise a working group like this on the most appropriate methodologies depending on the output sought. At a minimum, the socio-economic analysis could begin by replicating with updated data the analysis that was completed for the previous relicensing.

*§5.9(b)(7) –* ***Describe considerations of level of effort and cost, as applicable, and why any proposed alternative studies would not be sufficient to meet the stated information needs.***

Cost and effort would depend on the number of alternatives included in the analysis and the amount of existing information. We anticipate that most or all of the information needed for this analysis already exists, however the information would need to be analyzed and findings to be drafted. A potential cost of $20,000 to $80,000 may be reasonable for such an extensive analysis. This study will require several months to two years of effort to complete. The licensee did not propose any alternative studies.

**RE: Proposed Study Plan Comments for the Ripogenus (FERC No. 2572-133) and Penobscot Mills (FERC No. 2458-247) Hydroelectric Projects**

Dear Secretary Bose:

This is the United States Fish and Wildlife Service's (Service) response to the Proposed Study Plan (PSP) for the Ripogenus and Penobscot Mills Hydroelectric Projects (collectively referred to as Projects), located on the West Branch of the Penobscot River and Millinocket Stream in Piscataquis and Penobscot Counties, Maine. The PSP was submitted by Great Lakes Hydro America, LLC (GLHA; Applicant) on November 23, 2021. Subsequently, on December 15, 2021, and December 16, 2021, GLHA held virtual meetings to discuss the contents of the PSP and solicit stakeholder feedback during which the Service, and other parties, provided verbal comments and recommendations. After reviewing the PSP further, and attending the December meetings, the Service has the following comments.

## COMMENTS

General

On October 7, 2021, the Service submitted Pre-Application Document (PAD) comments and study requests for the Projects. In our PAD comment letter, the Service requested GLHA provide stakeholders with operational data (daily minimum, maximum, and average) for the last ten years, at all six developments, to understand how each facility is operated and how operations might affect the hydrology in the West Branch and mainstem Penobscot River. On October 8, 2021, the Federal Energy Regulatory Commission (Commission) issued staff comments on the PAD as well as an Additional Information Request (AIR) for detailed operations data to clarify

how the Projects are operated daily.[1] Specifically, the Commission requested GLHA include, as an appendix to the PSP, 10 years of operations data for each project, or each individual development, in the case of the Penobscot Mills Project, including (1) daily impoundment elevations; and (2) daily outflows (minimum, maximum, and average discharges). However, the requested data has not been provided to date.

> **Service recommendation:** During the PSP meetings, GLHA informed stakeholders, and the Commission, that it will provide the requested operations data as part of the proposed *Historic Operations Data and Assessment* study. However, said data are needed to understand current operations of the Projects, to inform the proposed studies, and the data should have informed stakeholders' responses to the PSP. Therefore, the Service requests GLHA provide the operations data for the Projects, as required in the Commission's October AIR, within 14 days of this correspondence.

GLHA states, "In regard to the Commission's fourth study criteria (i.e., §5.9(b)(4)), there is an extensive amount of information that was collected as part of the previous relicensing proceedings, which was a significant undertaking that studied and modified many aspects of the Projects' original licenses." However, the last relicensing proceeding, and associated studies, occurred when the operating regime was entirely different than it is currently, most notably the loss of the two paper mills for which the previous operating regime was designed to power.[2] Therefore, information, using the best and most updated methodology is needed to understand (1) the current operating regime at all six projects; (2) and how that operating regime might be affecting fish and wildlife within each project area.[3]

Additionally, GLHA states, "GLHA is proposing the studies that meets the criteria and are believed to be required for FERC to perform its environmental analysis for MDEP to issue the Projects' Section 401 Water Quality Certificates, and for FERC to develop the license requirements under which the Projects will operate for the term of the Projects' New Licenses." The Service notes, each study we submitted for this proceeding has been previously approved by the Commission during other hydroelectric dam relicensings in our region, which spans 14 states. Therefore, it is inaccurate to say that any of our studies do not meet the study criteria as outlined by the Commission. Additionally, it is important to note that the studies being proposed by the Applicant will not fully address several environmental issues that the Commission clearly identified in its November 22, 2021, Scoping Document 2 (SD2) as described throughout this letter, below.[4]

---

[1] Accession No. 20211008-3060

[2] As indicated in Volume 1 of the PAD, and the National Marine Fisheries Service's October 8, 2021 PAD comment letter (Accession No. 20211008-5254), during the previous relicensings of the Projects, a Water Use Plan (WUP) was developed which identified proposed operations of the Projects that intended to balance and manage multiple competing water uses (e.g., power generation, recreation, fisheries, minimum flows, flood control). Inherent to the WUP model was the goal to maximize energy production for two, now defunct, paper mills in the towns of Millinocket and East Millinocket. These paper mills closed in the mid 2000's. Since power generated at the Penobscot Mills and Ripogenus is no longer used exclusively by the Millinocket and East Millinocket paper mills but is instead used to maximize generation output, past assumptions on water use at the Projects are no longer relevant to current operations.

[3] This is more thoroughly described in the Maine Council Trout Unlimited's February 10, 2022, filing (Accession No. 20220210-5189).

[4] See pages 41 to 45 of SD2.

Studies Not Adopted

*3D Computational Fluid Dynamics Modeling Upstream and Downstream of the Discharge and in Vicinity of Powerhouse Forebays*

GLHA states, "GLHA believes that such a study is unnecessary and contrary to the MDIFW position of no change to the current upstream fish passage at the Projects to combat the continued spread of invasive species, which are a serious threat to Maine's wild and native species." However, during the PSP meetings, the Maine Department of Inland Fisheries and Wildlife (MDIFW) stated that it wasn't its intention to preclude diadromous fish from the West Branch but rather that invasive species management should be included in any fishway that may be implemented as a result of this licensing proceeding.

Further, GLHA states, "The requested CFD study would be best utilized as a tool to support the design phase of any upstream or downstream fish passage facility designs at the Penobscot Mills and Ripogenus Projects at a point in time when passage of anadromous fish species into the West Branch is occurring and reasonable management goals for anadromous fish species in the West Branch have been defined and agreed to among the state and federal resource agencies. Given this uncertainty, as well as potential changes in operations or infrastructure, which could occur at one of more of the Projects' developments over the next 15 years, the development of CFD models as requested are premature at this time."

> **Service recommendation:** The Service is amendable to delaying this modeling effort until the second study season; however, in the first study season GLHA should collect bathymetry data in each headpond (information necessary to develop the model). The requested CFD study will aid in the decision-making process related to mitigation measures at each development. For example, if the requested downstream eel studies show eels predominantly emigrate past one of the dams via the turbines and those eels have a high rate of mortality, the CFD will allow the Service to determine the angle of downstream racks that will achieve the optimal sweeping velocity to ensure safe, timely, and effective passage. Therefore, the Service recommends the Commission require the CFD study as part of this licensing proceeding.

*Evaluation of American Eel Size and Timing of Downstream Migratory Movements*

GLHA states, "Based on the expected low densities of American eel upstream of the Projects, it is unlikely that a sub-sample of nights during the anticipated downstream migration period would yield an adequate sample size from which to inform on timing and population size distribution. The use of an active sampling approach would need to be robust, requiring a significant amount of labor and incurring a large study cost for likely minimal information about eels at the Projects. Nor is an acoustic approach to sampling likely to be effective. GLHA evaluated the potential use of an acoustic approach to evaluate eel size and migratory movement at the Projects. Haro et al. (1999) noted several challenges with acoustic enumeration…"

Further, GLHA states, "Since neither of the two study methodologies outlined above are suitable for the Projects, and since there is already existing information on eel size and timing of out-migration in Maine, GLHA proposes to rely on the existing knowledge base of the timing and sizes of adult eels during downstream migration. Haro et al. (2003) characterizes the run timing of out-migrating American eels in Maine as occurring from early September to early November, with the peak occurring during September 15 and October 15. Shepard (2015), the most recent USFWS status review for the species, stated that eel migration in Maine occurs from August through October with peak passage in response to high river flows."

**Service recommendation:** While GLHA states that this study would be difficult to perform due to the methodologies proposed by stakeholders, said methodologies have been used by other applicants at hydroelectric dams throughout our region, which spans 14 states. Additionally, as stated during the PSP meetings, updated information regarding eel emigration timing in Maine is needed. The dates of emigration of silver-phase American eel (*Anguilla rostrata*) presented in Haro (2003) were compiled (1) from historic literature published prior to 1989; and (2) from a survey of management agencies for reported run timing dates from commercial weir catches prior to 2003. We note, weir catch data can be biased. For example, most silver eel fishing in New England began in September and stopped in November due to cold river temperatures. Additionally, the 2015 USFWS status review GLHA references in the PSP does not assess eel timing at dams above West Enfield (FERC No. 2600) or include the site-specific movement data needed to inform protection measures on the West Branch of the Penobscot River. Moreover, the data included in the status review, related to yellow eels, was data collected prior to the Penobscot Restoration Project which resulted in the removal of two dams on the river and saw the increase of flashboard heights at multiple projects.

As stated in our study request

> *The timing of downstream migration of adult eels is not defined for the West Branch of the Penobscot River and there is not information about the size of the eels attempting to move downstream past the six projects that comprise Ripogenus and Penobscot Mills. Therefore, the general effects of hydroelectric project operations on eel survival to the ocean are unknown. Although separate study requests have been submitted to address project-specific downstream passage route selection, delays, and mortality of eels, general characteristics (size) of eels moving downstream and of river flow and environmental conditions may have significant relationships with project operation and eel migratory success and survival. For example, eels may tend to move immediately before or during periods of significant precipitation (or consequently river flow), times at which projects may be generating at maximum capacity or spilling, which may, or may not, present a higher passage risk to eels. Conversely, periods of low flow may be associated with a significant proportion of total river flow passing through turbine units, which present additional, or different, passage risk to eels. If discrete conditions which promote eel downstream migration are known, it may be possible to take actions with respect to project operations which reduce or minimize passage risk (i.e., operation of a bypass, reduction of intake approach*

*velocities, directed spillage through a particular route at a project, etc). These studies should provide baseline information on river-specific downstream migration to predict when silver-phase eels are expected to migrate downstream in the West Branch, from which project operations could be modified to minimize passage risks.*

The Service notes, for the Commission's awareness, that we will be requesting this evaluation at hydroelectric dam relicensings throughout Maine moving forward (where timing information is based on trapping information or existing data is not suitable to inform downstream passage protection measures). While nighttime movement and migration is commonly reported in peer-reviewed, published, studies, daytime movement also occurs, as demonstrated in the Susquehanna River (Eyler et al. 2016; Travade 2010). If night-time (or periodic) shutdowns or other protective measures for eels are to be seriously considered at hydroelectric projects, site-specific movement data are needed. Without site-specific data, the dates used historically in Maine as defined by GLHA above are highly generalized, and potential mitigation measures implemented during this period, like nighttime shutdowns, may or may not be effective at protecting emigrating eels. Additionally, the Service notes that eel surveys conducted during subsets of days or seasons will only detect individuals present during those intervals and will not detect the actual movement patterns and abundance of eels at projects. Knowing that eels potentially move at all times of the year and throughout the day, more robust studies outside of previously defined windows of time are needed at hydroelectric projects to better define project impacts and identify appropriate, site-specific mitigation measures.

Ultimately, eels are migrating past the Projects that are part of this licensing proceeding, as indicated by the Applicant in the PAD and at the PSP meetings. Therefore, GLHA is obligated to protect eels as they attempt to emigrate downstream past each development. By performing this study as requested, the resource agencies and the Penobscot Indian Nation (PIN) can (1) assess any potential impacts related to project operations; and (2) develop adequate protection measures needed to meet management goals and objectives.

*Downstream American Eel Passage Alternatives Study*

No comment.

*Freshwater Mussel Survey*

The Service respectfully requests that the Commission approves this study as submitted in our October 7, 2021, PAD comment and study request letter. The PAD provided limited information on the distribution and abundance of freshwater mussels within the West Branch of the Penobscot River and within the vicinity of the Ripogenus and Penobscot Mills projects. As stated at the PSP meeting, the last freshwater mussels survey to be performed in limited sections of the West Branch River was in 2009 by MDIFW. Water manipulations and drawdowns from hydropower generation can decrease the amount of habitat available to mussels and can cause mortality to any mussels that might be exposed due to generation. The need for this information, a nexus, and appropriate methodology are explained further in our PAD comment letter.

Ultimately, the Service requests that GLHA conduct a mussel survey (1) in each project impoundment and bypass reach; and (2) in Project-affected reaches downstream from dams and powerhouses (e.g., Upper Gorge, Holbrook Side Channel, what GLHA is referring to as the "Back Channel", Millinocket Stream, etc.) to determine the species composition, distributions, and abundance of freshwater mussels, including the State-listed brook floater (*Alasmidonta varicosa*), yellow lampmussel (*Lampsilis cariosa*), and tidewater mucket (*Leptodea ochracea*).[5]

We note, the study submitted for this proceeding has been submitted at a number of proceedings throughout the Northeast and has either been adopted without issue by the hydropower owner or has been approved by the Commission.[6]

*Terrestrial Wildlife and Botanical Resources Study*

The Service respectfully requests that the Commission approves this study as submitted in our October 7, 2021, PAD comment and study request letter. The Project area contains habitat suitable for the Federally Threatened Northern Long-Eared Bat and may contain habitat suitable for the Federally Threatened Canada lynx and its designated Critical Habitat and, according to the PAD, multiple State-listed species may occur in the vicinity of the Projects (at all six developments). GLHA states it is not proposing any new construction, changes to current land management practices, or new land management activities as part of this licensing proceeding. However, the PAD provides no descriptions of the types of land management practices that GLHA currently employs. At the PSP meeting, GLHA stated they did not manage the land in any way but when asked by Commission staff if there was forest management occurring within the Projects boundaries, GLHA stated there was. Therefore, the Service reiterates its request for this study as originally written.

Without knowing what terrestrial resources currently exist and what wildlife occurs in the project areas (or what types of land management and/or maintenance activities GLHA routinely undertakes) the Service is unable to determine if impacts are currently occurring or if they may occur under any new conditions that could be imposed via a new license (e.g., additional recreational amenities such as trails). These information gaps need to be filled so that stakeholders can assess any potential impacts related to project operations and develop adequate protection measures to meet management goals and objectives. Plants and wildlife occurring in habitats in the project areas may benefit from protection, mitigation, and enhancement measures, given the potential effects of current and future operations and maintenance activities. Additionally, this information will help the Commission in forming a factual basis for a complete analysis of GLHA's application under the National Environmental Protection Act (NEPA).[7]

*Northern Long-eared Bat Acoustic Study*

[5] The brook floater is also a priority at-risk species for the Service.

[6] Fiske Mill (FERC No. 8615), Turners Falls (FERC No. 1889), Vernon (FERC No. 1904), Bellow Falls (FERC No. 1885), Wilder (FERC No. 1892), Cavendish (FERC No. 2489), Taftville (FERC No. 2662), Mine Falls (P-3422), etc.

[7] In SD2, the Commission lists the following as a preliminary environmental issue to be addressed in the NEPA, "Effects of continuing to operate the Projects on state-protected wildlife and plant species (e.g., little brown bat, eastern small-footed bat, wood turtle, etc.), including Species of Special Concern and Significant Wildlife Habitat listed under Maine's Natural Resources Protection Act and potentially in the project area."

No comment.

Studies Adopted with Modification

*Impacts of Water Level Fluctuations on Riparian and Aquatic Vegetation, including Invasive Species, Associated Wildlife, and their Habitats in the Ripogenus and Penobscot Mills Impoundments*

GLHA states, in the PSP, that this study was adopted with modifications and is addressed in the *Water Quality Study*. However, the goals of the *Water Quality Study*, as described in the PSP, is "…to collect contemporary water quality data, determine the composition of the Project's benthic macroinvertebrate community, and collect aquatic habitat data at the Ripogenus Project." Therefore, the proposed study does not address the goals and objectives outlined in our study request which are:

1. collect data on how water surface elevation changes hourly over the course of three years;
2. quantitatively describe and map wetland types within 250 feet of the shoreline, and describe associated wildlife;
3. delineate, quantitatively describe, and map all wetland types, including invasive species and wildlife observed (e.g., bald eagle nesting, waterfowl nesting, etc.) within 200 feet of the shoreline, and the extent of this habitat if it extends beyond 200 feet; and
4. quantitatively describe (e.g., substrate composition, vegetation type and abundance) and map shallow water aquatic habitat types subject to project operation inundation and exposure, noting and describing additional areas where water depths at the lowest operational range(s) are wetted to a depth less than one foot (flats, near shore areas, gravel bars, with very slight bathymetric change).

Consequently, the Service respectfully requests that the Commission approves the *Impacts of Water Level Fluctuations on Riparian and Aquatic Vegetation, including Invasive Species, Associated Wildlife, and their Habitats in the Ripogenus and Penobscot Mills Impoundments* study as submitted in our October 7, 2021, PAD comment and study request letter. The information that would be collected for this study is needed to determine whether existing operations affect plants, habitats, and wildlife in the project areas, whether aquatic vegetation and its habitats can be enhanced by modifications to project operations, or other mitigative measures, and whether there is any unique or important shoreline or aquatic habitats that should be protected. This information will also help the Commission in forming a factual basis for a complete analysis of GLHA's application under NEPA.[8]

*Upstream American Eel Passage Assessment*

[8] In SD2, the Commission lists the following as a preliminary environmental issue to be addressed in the NEPA, "Effects of continuing to operate the Projects on state-protected wildlife and plant species (e.g., little brown bat, eastern small-footed bat, wood turtle, etc.), including Species of Special Concern and Significant Wildlife Habitat listed under Maine's Natural Resources Protection Act and potentially in the project area."

The Service respectfully requests that the Commission approves this study as submitted in our October 7, 2021, PAD comment and study request letter. Performing an upstream eel passage assessment at just one of the six developments being relicensed is insufficient to inform potential protection, mitigation, and enhancement measures related to upstream eel passage at each dam. As stated in GLHA's PAD, and at the PSP meetings, eels are located in each of the impoundments associated with the Projects. Therefore, the Applicant is obligated to provide safe, timely, and effective passage to eels as they attempt to move upstream past each development. Additionally, while we appreciate GLHA's modifications to our study request, the Service does not support the methodology being proposed as it will not identify areas where juvenile eels are congregating at each dam. For example, bright spotlights are known to be ineffective at observing eels at night as these animals tend to shy away from bright lights; red headlamps should be used instead. Additionally, while binoculars have been used in relicensing studies in the past, this methodology is unreliable if the Applicant is unable to get close to the dams. The study, as requested by the Service in our October letter has successfully been performed at a number of hydroelectric projects in our 14-state region. The results of these studies have informed the implementation of upstream eelways and therefore the safe, timely, and effective passage of these animals.

While the Applicant states that they are not adopting our request for trap/pass collection to evaluate permanent eel passage at any of the six developments because "…given the likely low number of American eel at the site; passive methods are typically ineffective at sites with low American eel density", there is no information to support this statement as studies, to date, have not been performed at these projects to inform the density of eels. Moreover, the applicant gives no substantiated reason to reject a sampling timeframe that would accurately detect eel abundance and movement (i.e., April 1 to November 30, once per week). As stated in the *Evaluation of American Eel Size and Timing of Downstream Migratory Movements* section above, if we are only looking for eels during a certain period of time, or during certain times of the day, that will be the only times during which we observe eels. Knowing that eels potentially move at all times of the year, and throughout the day, more robust studies outside of previously defined windows of time are needed at hydroelectric projects in Maine, including the six developments that comprise Ripogenus and Penobscot Mills, to ensure safe, timely, and effective passage is provided during the duration of any newly issued license.

*Downstream American Eel Passage Assessment*

In the PSP GLHA states, "In lieu of conducting a large-scale, comprehensive field assessment, GLHA proposes to examine the question regarding potential effects of downstream passage on adult American eel at each of the Projects' developments through a desktop assessment." However, a desktop assessment will not provide information like route of passage, latent mortality, level of injury experienced by an eel as it attempts to pass the Projects, delay, how eels interact with each development as they move downstream, or the cumulative effects of passing the six developments that are part of this relicensing (Mensinger et al. 2021). This information is necessary to determine the effects of Project operations on the Service's trust species within the West Branch and the subsequent development of any mandatory terms and conditions for this licensing proceeding. This information will also help the Commission in forming a factual basis

for a complete analysis of GLHA's application under the NEPA.[9] Therefore, the Service respectfully requests that the Commission approves this study as submitted in our October 7, 2021, PAD comment and study request letter.

In addition to the above comments, the Service supports the study requests submitted by the National Marine Fisheries Service, the PIN, the Department of Marine Resources, MDIFW, Trout Unlimited, Ed Spear, and the other Non-Governmental Organizations (NGO's) participating in this proceeding.

Thank you for this opportunity to comment. Please direct any questions to Julianne Rosset at julianne_rosset@fws.gov.

Sincerely,

RE: Comments in Support of the February 22, 2022 Maine Department of Environmental Protection Study Request, Ripogenus Hydropower Project (FERC No. 2572) Impoundment Fish Assemblage Study. Accession No. 20220222-5171

On February 22, 2022 the Maine Department of Environmental Protection (MeDEP) filed a much needed Fish Assemblage Study Request. I fully support this request and its goals. However, understandably, MeDEP was reluctant to define precise methods and goals, the request as it stands is open ended. While the study request mentioned "the river" (West Branch) it was silent on the need for fish assemblage collections in the many tailwater reaches below specific project facilities. In the paragraphs below, I highlight data gaps to be filled and suggest other goals for the study.

Ripogenus Impoundment; The Maine Department of Inland Fisheries and Wildlife (MeDIFW) in its October 8, 2021 filing (page 6) referenced poor growth of Ripogenus Impoundment adult landlocked salmon (salmon) resulting from the lack of juvenile (Age 0+) smelt available as prey to the impoundment and downriver West Branch salmon populations. Other than the apparent scarcity of juvenile smelt, there is no quantifiable smelt data available e.g., age structure and abundance, spawning success, availability of food (zooplankton). It is

absolutely clear that MeDEP fish assemblage study includes smelt. Sampling of the impoundment smelt populations (ages 0-III+), at a minimum in the Caribou and Chesuncook basins, should be included in field study plans. These data are desperately needed to describe population dynamics.

MeDIFW has expressed the very reasonable concerns with the use of gill nets in project waters. Ripogenus Impoundment adult salmon are at perilous low levels and conventional gill netting should be avoided. There are a number of commonly used collection methods that target the relatively small sized smelt while avoiding by-catches of salmonid species. Lackey (1970) used fine mesh (1/4-1/2 inch) vertical nets in Echo Lake in coastal Maine. Gorman, O. (1984) used 0.5-m plankton nets ( of 0.355-, 0.450-, 0.560-, and 0.750-mm mesh). Trawls were used to collect Great Lakes smelt by Kirn and Labar (1996) and while studying Lake Champlain, they used night time trawling to collect Age I and older alewives and smelt. Simonin et al. (2012) used hydroacoustics, trawls, and gill nets to document vertical fish, including smelt, distribution. Hrabik and Magnuson (1999) collected rainbow smelt during the summer using “single mesh, 4-m-wide vertical gill nets of 19-, 25-, 32-, 51-, and 64-mm stretch mesh that extended from the surface to the bottom”. Olson et al. used slightly larger vertical nets (25 and 50 mm mesh size) in Lake Ontario to collect smelt and other prey species. The use of the vertical gill nets or some combination of the above referenced methods should provide the necessary insight into the smelt community while protecting the presently improvised Ripogenus Impoundment adult salmon population.

Downriver Tailwater areas: It appears that fish assemblage studies of the riverine reaches below project facilities were included in the MeDEP study request. In order for FERC staff to undertake the balancing act required in FERC licensing, the status of riverine salmonid fish need to be described in some

detail e.g., abundance, growth and seasonal habitat. It is extremely likely that night time boat electrofishing in areas such as Little A Deadwater (aka The Salmon Hole, drift boat take out), and just below e.g. a few hundred yards, North Twin, Millinocket (the Grinder Room) and Dolby Dams can accomplish these goals in a relatively short time frame (one night).

Thank you for the opportunity to comment on this critical study.

**RE: Tribal Concerns Regarding Dam Operations and Relicensing in Maine**

Dear Secretary Bose:

At an EPA Region 1 Tribal Leaders Summit held in October 2021, two Tribal Nations in Maine, the Penobscot Indian Nation and the Houlton Band of Maliseet Indians, raised concerns related to relicensing and fish passage operations of certain dams in Maine.

The Tribal Nations shared these concerns with EPA in the context of our statutory authority under the Clean Water Act, which establishes the national goal that water quality should provide for the protection and propagation of fish, shellfish, wildlife, and recreation in and on the waters of the United States. EPA coordinates closely with states and tribes to establish water quality standards for waters that protect these goals, including designated uses and water quality criteria to protect those uses.

The Penobscot Nation voiced concerns regarding the adequacy of fish passage on dams that impact waters where tribal members fish for sustenance in the west branch of the Penobscot River, including the Penobscot Mills Project dams, Ripogenus Dam and Stone Dam. In particular, the Penobscot Nation is troubled with the lack of flow over Stone Dam and the resultant dewatering of the west branch of the Penobscot River below Stone Dam. As a result of the Penobscot River Restoration Project, anadromous fish that have long been absent in the Penobscot River are now returning for the first time in over 100 years. It is for this reason that the Penobscot Nation is keenly interested in current relicensing efforts of a number of these dams to ensure adequate passage of key tribal cultural fish species, so that Penobscot tribal members can practice their cultural lifeways and reserved rights associated with sustenance fishing in waters within the west branch of the Penobscot River.

The Houlton Band of Maliseet Indians (the Band) expressed concern regarding adequacy of fish passage at dams on all rivers that flow into the Gulf of Maine. These dams impact fisheries in their watershed (St. John River) and the Band's related habitat restoration efforts. The Band identified

the Lockwood and Shawmut dams on the Kennebec River and dams in the Mousam River and Union River as particular areas of concern.

Consistent with the federal government's trust responsibility and EPA's authority under the Clean Water Act, in June 2020, EPA approved the State of Maine's submission of water quality standards that protect tribal sustenance fishing as a designated use for certain waters in Maine where tribal members fish for sustenance. To the extent that current dam relicensing efforts and issues associated with fish passage operations at existing dams impact the respective river watersheds that support sustenance fishing, EPA remains interested and supportive of protecting these interests.

While appreciating the need for developing and maintaining renewable energy resources, EPA strongly advocates for unfettered fish passage where possible, and for adequate fish passage where warranted. This is of particular importance for waters upstream of dams where tribal members fish for sustenance and where adequate fish habitat and presence is required to meet Maine's federally-approved water quality standards for waters classified as Class A and AA and accompanied by a standard that "aquatic life shall be as naturally occurs." [1] These include a number of tributaries in the west branch of the Penobscot River upstream of the dams listed above.

In past correspondence, EPA has commented on issues surrounding river restoration and the fate of legacy river flow impediments such as dams. By virtue of this letter, EPA is not commenting on any specific FERC-related dam relicensing efforts. However, EPA believes that restoration of aquatic habitat and unfettered, natural, self-sustaining runs of anadromous fish will greatly benefit the ecological function and health of these rivers and their respective watersheds in Maine, as well as protecting the health and cultural values of the tribal communities and others that depend upon these important natural resources.

As you know, EPA has various roles in the FERC relicensing process, including review of National Environmental Policy Act (NEPA) documents, oversight of the State of Maine's CWA 401 certification program, and requisite consultation under FERC's regulations at 18 C.F.R. § 5.1. EPA looks forward to ensuring the concerns raised in this letter are addressed through these various mechanisms.

Please contact CAPT Michael Stover, EPA Region 1 Indian Program Manager, at (617) 918-1123 or stover.michael@epa.gov should you have any questions.

Sincerely,

David W. Cash
Regional Administrator

Elbridge G Cleaves, Weston, ME.
COMMENTS TO FERC REGARDING WEST BRANCH PROJECT P-2572

While my wife and I have been avid fly fishers for years we had not fished the West Branch extensively until the past six years or so as seasonal campers at Big Eddy Campground. However, during my professional career as a manager and forester one of the firm's major clients owned the E2 of T3R12 around Ripogenus Lake and the southern part of Chesuncook - thus I am no stranger to issues relating to impoundments, FERC, flowage rights and the operators of dams, including Rip.

Therefore, my comments are based on observations about the apparent changes in the approach to the management of a public resource from the past owners to current, and the recent heavy manipulation of flows as it impacts anglers, fisheries, and the natural world in general.

1) Direct involvement in the angling community seemed to be a priority of prior owners, which meant "we are concerned and responsive to how we manage a public resource." Now current ownership does not seem to share that same approach. Was the approach of the prior owner an anomaly, or is a lack of direction and assignment of priority by FERC to the new?
2) it is understandable that the current management of water would be governed primarily by mitigating the effects of climate change but is that decision-making so focused on the bottom line it comes at the undue expense of anglers and the natural world. There must be a better way to address climate change than the huge fluctuations in flow demonstrated over the past few years especially during the drought of 2021. We fear something must change or what is at stake may soon become moot.
3) Many evenings after 5:00PM (when rafters are off the river) the flow dramatically dropped to the point where boat and/or canoe access to the river was severely impeded, if not rendered impossible. While these developments may be seen only an inconvenience, to us it is a disregard of anglers and a lack of understanding of fishing on the west branch. We believe the fish react accordingly by changing feeding habits and location and thus are in a constant state of stress with resulting negative impacts on health and numbers.
4) There have also been severe drops in water levels/flows (well below required minimums) caused by some combination of a computer glitch and/or lack of an override to the automated system. While I am far from an expert in understanding all the inputs and modelling used to regulate water flows and hydro dams, there must be an override to an automated system given the current vulnerability of infrastructure world-wide and the potential for devastating impacts on natural resources.
5) Lastly, the impact of low water especially if dropped precipitously and regularly heavily impacts the entomological and ecological balance of the river system. For us, the West Branch has demonstrated it is one of the most complex and prolific producer of "bugs" and a "challenge to fish" anywhere in Maine. This rich resource is the reason fishing the West Branch is revered by new and old alike. More people are coming to its banks than ever before and are leaving a portion of their resources to the economic betterment of the Katahdin region.

I recognize my comments above are more anecdotal than scientific but nonetheless are reflective of the sentiment of anglers I know that fish the river. If there is a lack of scientific evidence to support or refute these comments, then that gap needs fixing – not ignored or buried under the rug. Anglers and the fisheries need to have a stronger say in the affairs of the West Branch right along with the other benefactors including the rafters, kayakers and the millions of consumers who live in the down State megalopolis. Thank you,

Elbridge & Judy Cleaves

My history

My name is Edward Spear. Beginning in 1977 and continuing into the early 2000s I worked for (then) Great Northern Paper (GNP) as a fisheries biologist with my primary responsibility being the West Branch of the Penobscot River (WB) drainage (from the Quebec boundary to the Medway Dam). During this period, I collected and analyzed data and co-authored FERC applications for Big A, Ripogenus, Penobscot Mills, and the Storage Projects. During that time, I participated in numerous agencies, stakeholder, and Non Government Organizations workshops and meetings as well as overseeing mitigation and enhancement measures. I believe I qualify as an expert of the West Branch of the Penobscot River drainage. The following comments are a continuation of verbal testimony made on the evening of September 9, 2021 and should be regarded as expert testimony.

**Ripogenus Hydroelectric Project (FERC No. 2572), Yet Another West Branch of the Penobscot River Flow Violation Below McKay Station**

Recently, March 5th or 6th, 2022, West Branch of the Penobscot Rivers flows below McKay Station (West Branch) were reduced to 860 CFS. This flow violates a license minimum flow requirement of 1000 cfs as well as violating a spawning and incubation flow requirement of 1300 cfs. While the severity of environmental impacts of this dramatic flow reduction are unknown at this time, landlocked salmon (salmon) spawning success is threatened and aquatic communities' abundance further reduced. This most recent minimum flow violation by Great Lakes Hydro America is the most ecologically dramatic of the many 2021-2022 West Branch flow transgressions.

The Licensee's Pre-Application Document (PAD) proudly makes frequent reference to protection, mitigation, and enhancement (PM&E) measures. These measures were implemented by Great Northern Paper as part of the 1996 FERC license and for the most part have not been reevaluated in 20 plus years. The exceptions are lake level and flow management, so called, PM&E measures. The 2021 draining of the Ripogenus Impoundment and the dewatering of the West Branch, with the March 5, 2022 event being the most lethal, were obvious to all project visitors e.g., anglers, boaters, camp owners, campers, sightseers, etc. As the Licensee takes full credit for PM&E measures in the PAD, they must assume full responsibility for their actions when PM&E measures fail resulting in catastrophic biological loses e.g., loss/alteration of impoundment littoral zones,

the failure to provide suitable McKay Station flows resulting in the loss of flow into the Holbrook Bypass channel that was designed to support salmon spawning, incubation, and nursery life stages (Article 406), serious flow reduction and loss of downstream salmon spawning, incubation and nursey areas, and the loss of macro invertebrates communities abundance, function and diversity.

The Ripogenus license states*; Article 402 of the existing license requires minimum flows downstream of McKay Station into the West Branch as specified in Table 4.4-1. These flows may be temporarily modified if required by operating emergencies beyond the control of the Licensee and for short periods upon agreement between the Licensee and the Maine Department of Environmental Protection (MDEP) and Land Use Planning Commission (LUPC). Minimum flows may also be modified (to outflow approximates inflow) if required by hydrologic conditions beyond the control of the Licensee upon mutual agreement between the Licensee, USFWS, MDEP, LUPC, and MDIFW. Consistent with the August 19, 1997 FERC order approving and modifying the Water Management Plan, changes in flows below McKay Station are accomplished through the turbines; however, if necessary, GLHA will open a gate at Ripogenus Dam to augment flows.*

The key component of the above Article is: *hydrologic conditions beyond the control of the* licensee. Beginning in May 2021, the licensee had total control of Ripogenus storage as well as upstream storage in the Licensee's storage Project (P-2634). The Licensee's computer monitoring surely demonstrated falling lake levels with reduced inflow and weather forecasts provided little hope of significant precipitation. In managing storage, the licensee also chose to ignore Great Northern Paper's Water Management Plan. The use of 38 plus Billion Cubic Feet of useable storage including tributary inflow was a business decision designed to maximize energy production and profit. The licensee did so and depleted storage with total disregard of environmental needs. Fish, aquatic communities as

well as recreationalist paid the price and will continue to pay the price (in lost salmon reproduction) in 2022 and beyond.

The 1996 FERC Ripogenus License was based in part on the value of West Branch salmon fishery and “relatively stable base flows”. These conditions no longer exist. The 1996 license also provides some flow modification flexibility, however the licensee is required to consult with the resource agencies e.g., Maine Department of Inland Fisheries and Wildlife, the US fish and Wildlife Service and Maine Department of Environmental Protection. There are no FERC E-library filings that suggest possible consultations occurred. Another in a series of Ripogenus Project license violations that resulted in continuing environmental degradation.

If license conditions are to be meaningful, FERC needs to respond to the licensee’s continued disregard for conditions, guidelines and goals set forth in the 1996 FERC License. FERC must hold the licensee responsible for operational decisions, e.g., peaking, and high base flows, made when it was clear that no storage would be available to meet fall and winter environmental goals. FERC can not allow the Licensee to act as it pleases, the environmental communities will not survive, or survive in the manner described in the 1996 Environmental Impact Statement. Fish, aquatic communities and anglers need to be considered.

Thank you for the opportunity to comment.

Kimberly D. Bose,
Secretary Federal Energy Regulatory Commission First Street, N.E.
Washington, D.C. 20426

Subject: Ripogenus Project (FERC No. 2572); Minimum Flow Reductions Comments

Dear Secretary Bose:

I am writing in response to the letter submitted March 9, 2022 by Kevin Bernier of GLHA regarding minimum flow reductions in the Ripogenus Project. I greatly appreciate GLHA evaluating snowpack and recognizing the amount of water released from Ripogenus dam needed to be modified to support future water releases. In their letter, GLHA presents the drought as the sole cause of the current problem.

They claim, " *licensee for the Ripogenus (FERC No. 2572) and Penobscot Mills (FERC No. 2458) Projects, has been implementing water conservation measures on the Upper Penobscot since the current drought intensified beginning in 2020*," and provide the following as evidence of water conservation efforts:

> *1. The Canada Falls, Seboomook, Caucomgomoc, and Ragged Lake Developments have been largely operating at minimum flow, or at a reduced minimum flow developed through agency consultation, since the current drought began in 2020.*
>
> *2. Through agency consultation, the Ripogenus spawning and incubation flows (which are required from October 15th – June 7th) have been set at 1,300 and 1,100 cfs in 2020 and 2021 respectively, much lower than the 1,700 cfs flow that had been set annually the previous 7 years. GLHA has not deviated from the current 1,100 cfs minimum flow since it was set in October.*
>
> *3. Ripogenus flows have been routinely reduced during non-rafting hours (i.e., from 5:00 p.m. to 8:30 a.m.) to conserve water storage in the Ripogenus impoundment.*

I applaud these efforts, although I question the claim of reduced releases during non-rafting hours. Our experience on the lake and rivers has not reflected "routinely reduced flows during non-rafting hours." Throughout July and August of 2020 and 2021 we often saw releases above the minimum required and well beyond hours required. An example of daily releases is represented in the chart below, which is a screen shot from Brookfield's Water Flow site in August of 2021:

AS OF SAT AUGUST 14 11:41AM EDT

Total Flow 3100 cfs

## SHORT-TERM SCHEDULE

| START DATE | START TIME | END DATE | END TIME | CFS |
|---|---|---|---|---|
| 8/11/2021 | 8:00 AM | 8/11/2021 | 9:00 PM | 3,000 |
| | 9:00 PM | 8/12/2021 | 8:00 AM | 1,800 |
| 8/12/2021 | 8:00 AM | 8/12/2021 | 5:00 PM | 2,200 |
| | 5:00 PM | 8/12/2021 | 9:00 PM | 3,400 |
| | 9:00 PM | 8/13/2021 | 8:00 AM | 1,800 |
| 8/13/2021 | 8:00 AM | 8/13/2021 | 12:00 PM | 2,000 |
| | 12:00 PM | 8/13/2021 | 5:00 PM | 3,000 |
| | 5:00 PM | 8/13/2021 | 9:00 PM | 3,400 |
| | 9:00 PM | 8/14/2021 | 8:00 AM | 1,800 |
| 8/14/2021 | 8:00 AM | 8/14/2021 | 5:00 PM | 2,200 |
| | 5:00 PM | 8/15/2021 | 8:00 AM | 1,800 |
| 8/15/2021 | 8:00 AM | 8/15/2021 | 5:00 PM | 2,200 |

As the Short-Term Schedule indicates, water was generously released during non-rafting hours far exceeding minimum requirements. Rafting releases were also beyond minimum license requirements as explained by GLHA, "*Project license requires that minimum whitewater recreation flows of between 2,000 and 2,300 cfs be released from the Project between 0830 and 1700 hrs. on a daily basis.* ***In a "dry" hydrologic year (such as 2021), the required minimum flows are 2,200 cfs on Saturdays and Sundays, 2,000 cfs on Mondays and Fridays, and 1,800 cfs on Tuesdays through Thursdays.*** *During other hours of the day* ***outside of the whitewater release time period (i.e., 1700 to 0830 hrs), requires a minimum flow of 1,000 cfs*** *from June 8th through October 14th.*

Analysis of the Scheduled Flow Chart clearly demonstrates releases exceeding minimum requirements by as much as 2400 cfs. Releases between 1700 to 0830 hours exceed minimum flows by at least 800 cfs. If flows *"set at 1,300 and 1,100 cfs in 2020 and 2021 respectively,"* are *"much lower than the 1,700 cfs flow that had been set annually the previous 7 years"* are recognized as an important water conservation effort, certainly flows of 800 -2400 cfs beyond minimum requirements are recognized as significantly excessive.

There is no question lake levels are low and dramatically impacted by the drought. It is important GLHA and all of the stakeholders recognize the low water levels are also the result of project operations. GLHA states, *"Recent surveys in the upper Penobscot drainage have shown average*

*water content in the snow to be about 20% below the long-term average. In addition, water levels are currently much lower than normal in both the Ripogenus (almost 22 feet below full pond) and North Twin (almost 8 feet below full pond) impoundments.*" Twenty percent below average snowpack does not result in Ripogenus Impoundment being 22 feet below full lake – excessive water releases in a time of drought does.

In their letter, GLHA explains the reduced flows, "*are the same minimum flows implemented as the result of the most recent (2001 – 2003) extended severe drought in Maine."* We purchased our camp in 2003, and spent a large amount of time in the fall of 2002 on the lake deciding to make the purchase. At that time, despite a severe drought, the lake levels were not nearly as low as they are now, as evidenced by the fact that we were able to park our boat on the first mooring, something that has quickly become impossible in recent early summers. Family pictures show the lake in the fall of 2002 and spring of 2003 much higher than lake levels in recent years.

The purpose of this letter is to provide both anecdotal and empirical evidence that the low lake levels are not only the result of the drought, but that the problem has been exacerbated by operational practices. My hope is that this will provide the Commission with a clearer understanding of what is truly happening on the waterways. I also hope GLHA will acknowledge how operations have contributed to the problem so mistakes can be corrected, and future operations can be modified and improved.

Ten years of historical operations data has been requested by nearly all NGOs and government agencies involved in this process. The data exists. Within this data lies the facts necessary to make informed, accurate decisions, as recent events illustrate.

Relicensing these dams is a colossal undertaking that can only be done with an honest, accurate understanding of the realities of the situation, and with all parties involved engaged in good faith, cooperative efforts. FERC has the immense responsibility to balance the needs of all stakeholders involved. This can only be done with a complete and accurate picture of what dam operations have been over the current owners tenure, and the impacts of those operations on the rivers and lakes, fish and wildlife, and recreational users.

Thank you for your time and consideration.

Sincerely,
Kathleen K Houston

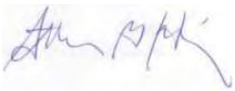
TROUT UNLIMITED
MAINE COUNCIL

**Via online submission to: http://www/ferc.gov**



Subject: **Comments of Maine Council of Trout Unlimited for the Ripogenus Project (P-2572)**

Dear Secretary Bose:

This responds to emails from Donna Burnett of FERC DocOps & Records Management transmitted March 17, 2022. We had posted a FERC issuance directly to two subdockets to ensure that FERC Compliance and FERC Relicensing staff were mutually aware of the issuance. We were informed that this is not allowed but that "You can submit the FERC Issuances as an attachment or as supporting documentation."

The FERC issuance is germane to both subdockets. Please file this document in its entirety to the subdockets. Its relevance is self-explanatory.

Respectfully,

Stephen G. Heinz

Maine TU Council FERC Coordinator

Attachment A – FERC Issuance of March 1, 2022; Subject: Allegation of Minimum Flow Deviations

**Office of Energy Projects**

Project No. 2572-134—Maine
Ripogenus Hydroelectric Project
Great Lakes Hydro America, LLC

March 1, 2022

VIA FERC Service

Kelly Maloney
Great Lakes Hydro America, LLC
150 Main Street
Lewiston, ME 04240-1398

Subject: Allegation of Minimum Flow Deviations

Dear Ms. Maloney:

This letter is in reference to September 21, 2021, January 5, 2022, and February 22, 2022 filings with the Federal Energy Regulatory Commission (Commission) alleging deviations from the minimum flow requirements at the Ripogenus Hydroelectric Project No. 2572. Minimum flow requirements are established by Article 402 of the project license.[1] Flow requirements vary based on date, time, and hydrologic year type, in order to facilitate the operations of the Penobscot Mills Hydroelectric Project No. 2458, salmon spawning, and whitewater recreation. Article 402 also stipulates that during generating unit failures at McKay Station, the minimum flow becomes 400 cubic feet per second (cfs), until the other flows required by Article 402 can be restored. Article 402 states that this should occur as quickly as possible, but outage-induced low flow events must be resolved within 3 days of the initial outage.

Trout Unlimited's September 21, 2021 allegation, which was supplemented on January 5, 2022, described potential deviations beginning around 1200 hours on August 30, 2021 and 0800 hours on September 16, 2021 and provided documentation of fish and macroinvertebrate strandings as a result of rapid declines in flows. We requested that

[1] Order Issuing License (77 FERC ¶ 61,066), issued October 22, 1996.

you respond to the allegation by letter dated September 21, 2021, and you filed your response with the Commission on October 14, 2021. The February 22, 2022 letter, from Mr. Ed Spear, broadly alleges that you have not adhered to the salmon spawning flows required by Article 402. The January 5 and February 22, 2022 letters also provide recommendations for the relicensing of the Ripogenus Project, which will be considered by the Commission's Division of Hydropower Licensing as part of the project's licensing proceeding; subdocket P-2572-133.

Regarding the allegations of noncompliance with your current license, you indicated that the August 30, 2021 and September 16, 2021 low flow events occurred as a result of unit outages. As such, you were required to provide 400 cfs, as measured using an hourly average, for a maximum of 3 days while resolving the outage.

**August 30, 2021 Low Flow Event**

On August 30, 2021, you were required to provide a minimum flow of 2,000 cfs for whitewater recreation during a dry hydrologic year. At 1205 hours, a unit tripped due to thunderstorms in the area, activating the 400 cfs minimum flow requirement. You report that you experienced an instantaneous low flow of 109 cfs immediately following the unit outage, but you were able to restore flows above 400 cfs within 13 minutes, resulting in an hourly average flow that remained in compliance with Article 402. You were able to restore the whitewater boating flows of 2,000 cfs by 1530 hours the same day. You note that you did not notify the Commission of the event, as it was not a deviation from the Article 402 requirements; however, you provided a courtesy notification to the U.S. Fish and Wildlife Service, Maine Department of Environmental Protection, and Maine Department of Inland Fish and Wildlife. No agencies provided comments.

**September 16, 2021 Low Flow Event**

On September 16, 2021, you were required to provide flows of 1,000 cfs for the protection of spawning salmon. A non-project transmission line disturbance caused a unit trip at McKay Station at 0731 hours, causing an instantaneous drop in flow to as low as 118 cfs. You were able to restore flows to 400 cfs within 5 minutes, maintaining a compliant hourly average, and to 1,000 cfs by 0958 hours. As with the August 30, 2021, low flow event, you did not report it to the Commission, as it was not a deviation from license Article 402; however, you did provide a courtesy notification to the resource agencies but received no comments in return.

**February 22, 2022 Filing**

On February 22, 2022, Mr. Ed Spear filed an additional allegation, broadly stating that you have not complied with the salmon spawning protection flows required by Article 402 and in doing so, not complied with the salmon habitat improvements required by Article 406.[2] The filing alleges that the fall low flow events were preventable, as ample water was available, and that any flows below 1,000 cfs should be considered a violation of your license. As discussed above, Article 402 of the license allows for flows as low as 400 cfs in the event of a unit outage, but salmon protection and whitewater boating flows should be restored as soon as possible.

Based on our review of the available information, it appears that the alleged deviations were permissible low flow events which occurred after unit outages. You acted quickly to maintain 400 cfs baseflows and to restore whitewater rafting and salmon spawning protection flows. We understand that sharp declines in flow are difficult to avoid following unit trips, that the redistribution of flows after a unit trip requires time to safely open gates or start other units, and that you have been able to restore flows reasonably quickly during such events. However, Trout Unlimited's and Mr. Ed Spear's concerns with the resulting environmental effects are valid. Therefore, after filing the requested operational data with the Commission in the relicensing proceeding,[3] we encourage you to work with Trout Unlimited, the resource agencies, and Commission staff to develop a proposal to address strandings and include it in the final license application you file by September 30, 2024. In the meantime, we also encourage you to conduct aquatic habitat surveys immediately following any future unit outages, if time allows prior to restoration of flows. Surveys should determine if any adverse environmental effects are occurring, and if so, you should consult with the resource agencies to determine any appropriate actions needed during those low flows.

[2] Order Approving Recommendations of Habitat Improvement Plan Under Article 406 (102 FERC ¶ 62,116), issued February 20, 2003.

[3] See Commission staff's October 8, 2021 letter.

Thank you for your cooperation. If you have any questions regarding this letter, please contact Alicia Burtner at (202) 502-8038 or alicia.burtner@ferc.gov.

Sincerely,

Andrea Claros
Chief, Aquatic Resources Branch
Division of Hydropower Administration
and Compliance

Greg Labonte, Gorham, ME.
For over a decade I have watched the native salmon of the west branch decline due to poor water regulations. The economic stimulus of excellent fishing is an absolute must for an already economically deprived area. Excellent fishing is dependent on regular flows. Last fall, September 30th, the water was so low, I could have walked across the river at any point. Class 5 rapids had become class 1. This time of year is critical for salmon spawning success. There may have even been salmon stranded in side pools the water was so low. Trout Unlimited is trying to conduct a study to determine how many salmon get stranded at a critically low water level. If this study reveals even a handful of salmon, there must be safe guards put in place to stop this from happening. The west branch is a unique resource, very few places on earth have such a resource. If we squander it with poor dam management, we will be repeating history, not learning from it.

Brookfield Renewable

March 23, 2022

***Via Electronic Filing***

Kimberly D. Bose, Secretary
Federal Energy Regulatory Commission
888 First Street, NE
Washington, DC 20426

**Subject:** **Ripogenus Hydroelectric Project (FERC No. 2572-133)**
**Penobscot Mills Hydroelectric Project (FERC No. 2458-247)**
**Revised Study Plan**

Dear Secretary Bose:

Great Lakes Hydro America, LLC (GLHA), a subsidiary of Brookfield Renewable and Licensee of the Ripogenus Hydroelectric Project (FERC No. 2572) and Penobscot Mills Hydroelectric Project (FERC No. 2458) (collectively referred to as the "Projects"), herein files with the Federal Energy Regulatory Commission (FERC or Commission) the Revised Study Plan (RSP) for the relicensing of the Projects. The Projects are located on the West Branch of the Penobscot River and Millinocket Stream in Piscataquis and Penobscot Counties, Maine.

On June 11, 2021, GLHA filed the Notices of Intent and Pre-Application Document (PAD), which initiated the formal relicensing proceeding to obtain two separate new licenses for the continued operation of the Projects through the Commission's Integrated Licensing Process (ILP). Subsequently, FERC issued Scoping Document 1 (SD1) on August 10, 2021 and held daytime and evening virtual scoping meetings on September 9, 2021.[1] Additionally, on the afternoon of September 9, 2021, GLHA hosted a virtual environmental site review.

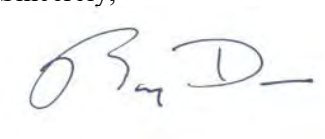
Between June 11, 2021 and October 13, 2021, a total of approximately 50 stakeholders filed written correspondence with FERC providing general comments, comments regarding the PAD, comments regarding SD1, and/or study requests. On November 22, 2021, FERC issued Scoping Document 2 (SD2). Also on November 22, 2021, GLHA filed a single Proposed Study Plan (PSP) for the Projects. GLHA hosted a two-day virtual PSP meeting on December 15 and 16, 2021 to provide stakeholders the opportunity to review, comment, and ask questions related to the PSP. Between October 14, 2021 and March 7, 2022, a total of approximately 31 stakeholders filed written correspondence with FERC providing general comments, comments regarding SD2, and/or study requests. In total, approximately 38 study requests were filed with FERC.

GLHA has carefully evaluated and considered all comments and study requests filed in response to the PAD, SD1, SD2, and PSP, and has incorporated, or otherwise addressed, these comments and study

[1] As specified in SD1, the Commission did not conduct in-person public scoping meetings or in-person environmental site reviews due to concerns with COVID-19.

Great Lakes Hydro America, LLC
1024 Central Street
Millinocket, ME 04462
www.brookfieldrenewable.com
Tel: 207.723.4341
Fax: 207.723.3948

requests in this RSP. As listed below, GLHA is proposing to conduct 16 studies, which wholly or partially address more than 20 study requests.



1. Water Quality Study consisting of the following components:
    a. Impoundment Trophic State Study (Ripogenus & Penobscot Mills Projects)
    b. Impoundment Aquatic Habitat Assessment (Ripogenus & Penobscot Mills Projects)
    c. Downstream Temperature and Dissolved Oxygen Study (Ripogenus & Penobscot Mills Projects)
    d. Riverine Aquatic Habitat Assessment (Ripogenus & Penobscot Mills Projects)
    e. Benthic Macroinvertebrate Assessment (Ripogenus & Penobscot Mills Projects)
2. Instream Flow and Habitat Assessment of West Branch downstream of Stone Dam Study (Penobscot Mills Project)
3. North Twin Impoundment Tributary Access Survey (Penobscot Mills Project)
4. Upstream American Eel Passage Assessment Study – Presence, Distribution, and Relative Abundance of Juvenile Eel (Penobscot Mills Project)
5. Desktop Downstream Eel Passage Route and Survival Study (Ripogenus & Penobscot Mills Projects)
6. Recreation Study (Ripogenus and Penobscot Mills Projects)
7. Whitewater Boating Assessment Study (Ripogenus and Penobscot Mills Projects)
8. Aesthetic Study (Ripogenus and Penobscot Mills Projects)
9. Historic Architectural Survey (Ripogenus & Penobscot Mills Projects)
10. Historical Operations Data and Assessment Study (Ripogenus & Penobscot Mills Projects)
11. Operations Model Study (Ripogenus & Penobscot Mills Projects)
12. Wood Turtle Habitat and Presence Evaluation Study (Ripogenus & Penobscot Mills Projects)
13. Marsh Bird Survey Study (Ripogenus Project)
14. Furbearer Survey Study (Ripogenus Project)
15. Common Loon Management Plan Assessment Study (Ripogenus Project)
16. Riparian and Littoral Habitat Assessment Study (Ripogenus & Penobscot Mills Projects)

Additionally, as requested by FERC and various stakeholders, GLHA is providing daily operations data from 2010-2021 for each development associated with the Projects. The information can be found in Appendix S of the RSP.

Concurrent with this filing, GLHA is providing a copy of this letter to all parties listed in the attached distribution list. Parties with interest in the upcoming relicensing can download an electronic copy of the RSP from FERC's eLibrary system at https://www.ferc.gov/docs-filing/elibrary.asp by conducting a search using the docket numbers p-2458 and/or p-2572.

If you have any questions regarding the RSP, please contact me by phone at (207) 775-5605 or by email at randy.dorman@brookfieldrenewable.com.

Sincerely,

Randall Dorman
Licensing Manager
Brookfield Renewable

Washington, D.C. 20426

**RE: Comments on the Revised Study Plan for the Ripogenus (FERC No. 2572) and Penobscot Mills (FERC No. 2458) Hydroelectric Projects**

Dear Secretary Bose:

On March 23, 2022, Great Lakes Hydro America, LLC (GLHA) filed its revised study plan for the Ripogenus (FERC No. 2572) and Penobscot Mills (FERC No. 2458) hydroelectric projects on the Penobscot River in Maine. Despite our comments filed on February 7, 2022, the revised study plan indicates that GLHA does not intend to adopt our recommended studies at the project. We continue to disagree with GLHA's decision and stand by our request for the following studies at the projects: 1) Indicators of Hydrologic Alteration Model; 2) Project Effects on River Temperature in the West Branch; and 3) Future Flow and Water Temperature Study.

On October 8, 2021, the Commission issued an Additional Information Request for detailed operations data needed to clarify how the projects are operated on a daily basis. Specifically, the Commission requested GLHA include 10 years of operations data (in excel format) for each project, and that this information be filed with GLHA's proposed study plan on, or before November 23, 2021. None of the requested data were provided by GLHA by the Commission's November 23 deadline. In response, NMFS filed a comment letter on GLHA's proposed study plan, dated February 17, 2022, where we once again asked that GLHA provide this data as well as hourly outflow data for McKay Station, North Twin, Dolby, Millinocket, and East Millinocket Projects for the last 10 years; these data are critical to inform the development of proposed studies for the Ripogenus and Penobscot Mills projects. It wasn't until March 23, 2022 concurrent with issuance of GLHA's revised study plan (four months after the Commission's deadline) that some of the data that were requested were provided, leaving only 15 days for the agencies and stakeholders to review and comment on ten years of data. Given that GLHA failed to provide this data in accordance with the timeframe set forth by the Commission, or on a timeframe that would allow for this data to be considered in any proposed study plan, we are requesting that the Commission grant the agencies and stakeholders an additional 60 days on the deadline to file comments on the revised study plan. This time is necessary to allow the agencies and stakeholders sufficient time to review this information and incorporate it into our responses to GLHA's revised study plan.

In addition, we are reiterating our request for hourly flow data downstream of each generation facility in the Penobscot Mills and Ripogenus projects. While we specifically requested this data in our February 17, 2022, comment letter on the Proposed Study Plan for the projects, GLHA did not provide the data with the Revised Study Plan. This data is readily available to GLHA as evidenced by the March 10, 2022 letter to FERC where GLHA submitted hourly flow data at McKay Station for September 7, 2021. We are asking that this data be provided by April 15, 2022. The April 15 deadline and 60 day extension on the review will allow the agencies and stakeholders sufficient time for the review of ten years of operations data in order to provide comprehensive comments on the RSP. All parties to this relicensing must have a precise understanding of the mode of operating the Ripogenus and Penobscot Mills projects to identify potential effects to environmental resources in the project areas. We will use the additional 60 days to analyze project outflows and impoundment elevations to provide FERC with well-informed comments on the RSP which will ultimately benefit the environmental assessment for this relicensing.

If you have any questions or need additional information, please contact Dan Kircheis (Dan.Kircheis@noaa.gov) or 207-866-7320.

Sincerely,

Julia E. Crocker

Julie Crocker
Chief, ESA Fish, Ecosystems, and Energy Branch

Ripogenus Hydroelectric Project
FERC No. 2572

Penobscot Mills Hydroelectric Project
FERC No. 2458

# AMERICAN WHITEWATER AND APPALACHIAN MOUNTAIN CLUB COMMENTS ON REVISED STUDY PLAN REGARDING THE RIPOGENUS HYDROELECTRIC PROJECT (P-2572) AND PENOBSCOT MILLS HYDROELECTRIC PROJECT (P-2458)

American Whitewater ("AW") and Appalachian Mountain Club ("AMC") submit the following Comments in response to the filing of the Revised Study Plan ("RSP") for the Ripogenus Hydroelectric Project and Penobscot Mills Hydroelectric Project (FERC Project Nos. P-2572, P-2458) by Great Lakes Hydro America, LLC ("GLHA" or "licensee"), to inform FERC's development of the Study Plan Determination.

AW and AMC have long been involved with the FERC licensed hydropower projects in Maine, including hydropower projects located on the Penobscot, Kennebec, Rapid, and Magalloway rivers, and are party to settlement agreements that provide for whitewater boating opportunities that partially mitigate for project impacts at many of these projects. Our organizations participated in the initial scoping meeting and filed comments; submitted PAD and scoping comments, as well as study requests for these Ripogenus and Penobscot Mills projects; and commented on the licensee's Proposed Study Plan. We file these comments to address remaining deficiencies in GLHA's Revised Study Plan ("RSP") in relation to study requests by our organizations and other stakeholder in the FERC relicensing to adequately understand the aesthetic, ecological and recreational impacts of project operations in, below and in proximity to the project boundary. We request that FERC consider these comments along with those filed by resource agencies, and other stakeholder groups in developing a Study Plan Determination that will provide the necessary information to will inform the environmental analysis of project effects on non-developmental resources.

American Whitewater is a national non-profit 501(c)(3) river conservation and recreation organization founded in 1954. With approximately 6,000 members and 100 affiliate clubs, representing tens of thousands of whitewater paddlers across the nation, American Whitewater's mission is to protect and restore our nation's whitewater resources and to enhance opportunities to enjoy them safely. Our members are primarily conservation-oriented kayakers and canoeists, many of whom live and/or engage in recreational boating in the New England region within easy proximity of the Penobscot River. American Whitewater has long been involved with the FERC licensed hydropower projects in the Maine, including hydropower projects located on the Penobscot, Kennebec, Rapid, and Magalloway rivers, and are party to settlement agreements that provide for whitewater boating opportunities that partially mitigate for project impacts.

Since 1876, the Appalachian Mountain Club has promoted the protection, enjoyment, and understanding of the mountains, forests, waters, and trails of the Appalachian region. AMC is the largest conservation and recreation organization in the Northeast with more than 90,000 members, supporters, and advocates, many of whom visit the lands and waters upstream and downstream of the projects for recreation.

## Comments

Comments on Appendix F – Recreation Study Plan

The RSP only slightly expands the scope and methodology of the licensee's proposed Recreation Study Plan to include an assessment of boat access to the project impoundments, a recreation user survey, and to include winter use in the assessment. AW and AMC appreciate the inclusion of these items in the study scope but reiterate our request that the scope of the study also include all formal and informal recreation sites as well as those recreation sites located near and adjacent to the projects, which would also expand the scope of the assessment as outlined in 4.1.5 of Scoping Document 2 ("SD2").

Though AMC and AW appreciate the inclusion of a recreation user intercept surveys in the study methodology, we request that the study methodology also include an online survey, input from a stakeholder working group, and key person interviews with organizational representatives from user groups, representatives of camp owners and other recreation related interests, such as outfitters. It is not practical for our organizations or, for example, a camp owner on one of the lakes, rivers, or upland areas to be expected to travel to a FERC approved recreation site to complete the survey, nor does the survey instrument speak to the feedback of these audiences as a broader representation of the needs, opportunities and issues that would be brought forward by these audiences. Expanding the study methodology to include these engagement methods will ensure that the interests of recreational users are well captured and not based solely on the opinions of the intercept survey respondents, which may or may not reflect the broader feedback and needs of that user group. Expanding the study geography to also include informal access sites and recreation areas near and adjacent to the projects will ensure a better understanding of recreational uses, preferences and related issues and should be included in the study methodology. We acknowledge that some of this information may be better captured though an online survey, stakeholder working group, and key person interviews, than collected by intercept as informal recreation areas are hard to identify and staff for a traditional intercept survey.

Comments on Appendix G – Whitewater Boating Assessment Study Plan

The licensee has proposed a Whitewater Boating Assessment Study in the RSP, which AW and AMC requested, and which FERC acknowledged in SD2 as resources to be evaluated in the NEPA document. AW and AMC welcome the licensee's addition of this study in the RSP but wish to ensure that the study is conducted in accordance with the industry standard methodology and is inclusive enough in scope to adequately assess whitewater boating opportunities impacted by the projects using data, information and methodologies that are current.

Specifically, the licensee, in Section 10.0, Deviations from Requested Study, proposed a "Whitaker-type study" and further explains that "the requested flow study is unnecessary…". AW and AMC disagree with this deviation and the notion that the outcome and findings of assessment conducted can be pre-judged as the licensee has done here. Whitaker 2005 provides an industry standard methodology that is incremental, such that Level 1 is used to determine if a Level 2 or 3 analysis is needed. FERC should correct this misunderstanding in issuing a Study Plan Determination that follows Whiteaker 2005 and requires that a Level 2 and/or 3 study will be included in the study methodology if deemed necessary during Level 1 on each of the four river reaches identified in our study request and reflected in the study scope.

In Section 2.0, the licensee describes the goals of the study, which misrepresent the needs of the study to inform the FERC NEPA process as described in SD2. The goals of the study should be to evaluate flows for paddlers on four reaches of the river (Upper Gorge, below McKay Station, below Stone Dam, and Millinocket Stream), and not to solely "use existing information and paddler knowledge", as proposed by the licensee. It is inappropriate to list the goals of the study to discount the potential need to conduct a Whitaker Level 2 or 3 study if deemed appropriate. The objectives of the study are also inadequate as they follow the language of the goals and do not indicate that a Level 1 Whittaker study may indicate that a Level 2 or 3 study is needed.

In section 5.0, the licensee describes Background and Existing Information. Regarding the Upper Gorge Below Ripogenus Dam, we believe that the licensee inaccurately describes this reach as "unsafe" and with difficult access, neither or which are correct characterizations. The licensee is unqualified to make determinations of boating safety. The licensee cites numerous examples online of publicly available videos of kayaks, canoes and rafts using this reach, demonstrating both that this reach is safe to navigate at certain levels by experienced boaters, and that access is currently possible. This language should not be included in the FERC Study Plan Determination.

Specific to the West Branch Below Stone Dam, SD2 and the comments of AW, AMC and Maine Department of Conservation, Division of Parks and Public Lands on the PSP requested that the West Branch below Stone Dam be assessed to adequately evaluate the needs and opportunities related to this resource for whitewater boating and other recreation. In the RSP, related to Stone Dam in section 5.0, AW and AMC believe the licensee is seeking to justify their lack of interest in following the Whitaker 2005 methodology by arguing that flows needed for such an analysis cannot be provided. AW and AMC find this assertion to be unclear and inconsistent with other publicly available information related to the operating parameters of the Stone Dam.

Though the licensee claims that the inflatable flashboards that have replaced the old gate structures at Stone Dam prevent the licensee from conducting a controlled flow study in this reach, AW and AMC find this contradictory to filings on this project to the Low Impact Hydropower Institute in their application and the reviewer's report in that docket (https://lowimpacthydro.org/lihi-certificate-167-millinocket-dolby-hydroelectric-project-maine/). Regarding the Stone Dam inflatable structure, the LIHI docket notes that Stone Dam may be used to attain the 2,000 cfs minimum flow downstream of the Millinocket Project when the Millinocket project is offline. The LIHI docket notes that, "During periods of high seasonal flows or whenever abnormal conditions occur such that turbine flow [at the Millinocket Project] cannot be passed to achieve the 2,000 CFS minimum flow, the pneumatic rubber flashboard

system [at Stone Dam] is deflated to release flows in an expeditious effort. When this occurs, a two-minute siren warning is initiated and a safe flow of 200 CFS is released for fifteen minutes. Increases of 400 CFS per hour are made until either the required downstream flow is met, the elevation at Stone Dam falls to 459.45 FTMSL or the pneumatic rubber flashboard system is fully deflated. The ramping down of flows in the Back Channel is initiated once turbine hydraulic capacity is restored or seasonal flows start returning to normal." Provided that this information is accurate, it appears that Stone Dam can be operated in such a manner to assess whitewater paddling with an on-water component as part of the study if deemed necessary after Whitaker Level 1 study through single flow or multiple flow on-water study. This should be corrected in the Study Plan Determination.

Though we appreciate that the licensee will "redouble" its efforts to locate available information on this reach below Stone Dam, absent data being available that was collected consistent with the Level 1 Whitaker methodology, AW and AMC reiterate our request to follow the Whitaker methodology to assess whitewater in this reach through all three study levels as appropriate. It is inappropriate for the licensee to argue that "sufficient information exists" as articulated in section 10.0 when that information has not been located and may not be located during this licensing proceeding for this reach.

In section 7.0, the licensee proposes components of the methodology for the Whitewater Boating Assessment Study. In section 7.3, the licensee proposes Paddler Interviews and Surveys. AW and AMC believe that this is an important component of a Whitaker 2005 Level 1 study, though we wish to collaborate with the licensee to help identify boaters and other paddling related organizations that can assist in identifying potential respondents. No information is provided on the number of respondents sought, and we propose that a small sample size may not provide adequate information. In 7.4, Report Preparation, AW and AMC agree with the licensee that the report should "include recommendations regarding the need for further evaluation of whitewater boating conditions in the four study reaches," though we are troubled that the licensee is not proposing any next steps, if deemed necessary, as articulated in 2.0, Goals and Objectives. This inconsistency should be corrected by adjusting the language of the study Goals and Objectives to ensure that, if appropriate, the licensee will proceed to a Whitaker Level 2 or 3 analysis for one more of the four study reaches.

The licensee includes a Whitewater Boating Assessment Study – Interview Survey Form in the RSP. AW and AMC appreciate reviewing and commenting on the draft survey instrument. We also request that all surveys conducted be included in their entirety in the Initial Study Report, as scanned or photographed copies, and that the licensee not simply digitize or aggregate this valuable data. First, it is unclear how surveys will be completed "In person" as shown on the survey instrument. We welcome the licensee visiting local rafting outfitters, river access points and engaging directly with paddlers in-person, and we suggest that the recreation survey intercepts planned also have the whitewater survey on hand for whitewater padders to complete if found at a recreation site. We suggest expanding the survey to include an online opportunity for respondents and a kiosk style take and drop methodology, which will be able to reach a much larger audience. Specifically on question number 9, AW and AMC prefer that the survey instrument not just project a yes or no response to whether a reach is boatable and a suggested classification range, but also an opportunity for a narrative description of the experience, either

categorized as too high, high, medium, low, too low and/or a 1-5 scale of the quality and enjoyment of the experience at the identified flow as was included in question 5. The goal of the study is not just to assess what flows can be navigated, but to understand user flow preferences and enjoyment. Gathering the data from question number 5 and 9 are the best opportunities to fully capture user satisfaction and preferences. Though question 15 provides an opportunity for a respondent to note how they become aware of river flows, we know that at least three of the four reaches in the study area do not have any available information online or provided by the licensee and rely solely on visual confirmation made on site by paddlers. An addition question should be added that asks, "How would you prefer to find out about river flows occurring in this reach in the future?" to provide recommendations for how best to share this information with the public.

In summary, AW and AMC look forward to working with the licensee on the Whitewater Boating Assessment Study. We request that FERC issue a Study Plan Determination with a methodology following Whitaker 2005, not a "Whitaker-like" study, which has is not the industry standard. AW and AMC also believe that the licensee identifies much existing literature and data that will help inform this study and should help ensure that the Whitaker Level 1 component can and will be completed, informing the need or lack thereof to continue to a Whitaker Level 2 or 3 study.

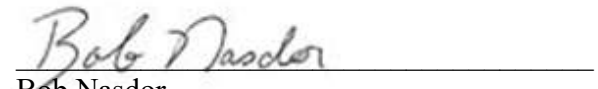
Comments on Appendix H – Aesthetics Study Plan

AW/AMC requested that the licensee conduct an aesthetics study. We appreciate and acknowledge that the licensee is proposing to conduct an aesthetics resources study focused on the use of Key Observation Points at FERC-approved Project recreation sites and from other KOPs frequently used by the public, which are identified in Table 1 and 2, though we are concerned that the proposed study will rely exclusively on "photo and video documentation" and will not solicit or incorporate feedback from the public related to the documentation collected and may also lack an analysis of the documentation which would be needed to inform the NEPA analysis and future license conditions.

We recommend that the licensee form an aesthetics study working group to further identify KOP's in the project boundary and in areas affected by project operations. This working group can also work with the Licensee to further refine survey instruments and data collection methods such as intercept and online surveys, as well as to engage with the licensee in reviewing the study data to assist in analyzing this data to be included in the Initial Study Report. We recommend that the working group include our organizations, resource agencies, and other interested stakeholders. The licensee should also further specify that the aesthetic evaluation will be conducted by the working group and other stakeholders on-site rather than solely relying on a review of photographic documentation of its facilities and operations.

Comments on the Socioeconomic Study as Proposed but Not Adopted in the RSP

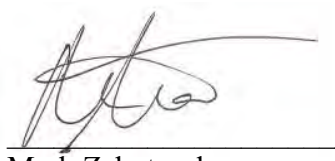
The licensee did not adopt the Penobscot Indian Nation's proposed socioeconomic study, to which AW and AMC respond by requesting that FERC require this study in the Study Plan Determination. AW and AMC commented in our PSP filing that significant changes in the



region have occurred due to the closure of the Great Northern mill, previously tied to the projects, which requires that FERC evaluate the current socioeconomic conditions to ensure that non-developmental values are balanced appropriately and support the outdoor recreation economy, that the licensee acknowledges is significant and the primary driver in the region. The licensee, furthermore, agrees that significant changes have occurred in the region since the last licensing proceeding, as articulated in the RSP. Specifically, regarding nexus, the licensee notes that the projects were previously connected directly to the paper mills that are now defunct and the licensee acknowledges that the projects provide whitewater releases below McKay Station that support a noteworthy commercial outfitting business, which alone should demonstrate that the projects have nexus to socioeconomic issues in the region and that these impacts should be evaluated in this licensing proceeding, as they have changed significantly since the last licensing proceeding and would inform FERC's NEPA analysis and possible license conditions.

AW and AMC request that FERC require a socioeconomic study as a component of the Study Plan Determination. The licensee's responses to the study request in the RSP fail to demonstrate that the requested study lacks nexus, as the licensee acknowledges the significant socioeconomic changes in the region since the last licensing proceeding, and the licensee provides a boilerplate response to nexus issues that is neither relevant, credible, or specific to the study request of the Penobscot Indian Nation. Furthermore, the licensee argues that the Penobscot Indian Nation's study request lacked a recommended methodology for this study. AW and AMC recommend that the licensee follow the methodology conducted in the Klamath relicensing socioeconomic study, FERC Project P-2082, in which the licensee provides a study that characterizes the current socioeconomic condition and future trends, including population, housing, economic development, local and tribal government budgets, public service, recreational resources, and transportation and utility infrastructure. A stakeholder working group should be established to advise the licensee on the full scope of the socioeconomic study and to provide additional guidance on the study goals, methodology, techniques, and analysis. AW and AMC disagree that these components would be addressed in other studies to be performed. Finally, AW and AMC believe that the findings of this study will inform FERC's NEPA analysis and will inform the development of licensing conditions that will better balance developmental and non-developmental values appropriate to the current and future trends of the region socioeconomically.

## Conclusion



Thank you for considering these comments.
