Comments on Appendix G – Whitewater Boating Assessment Study Plan
The licensee has proposed a Whitewater Boating Assessment Study in the RSP, which FERC acknowledged in SD2 as resources to be evaluated in the NEPA document. I welcome the licensee's addition of this study in the RSP but wish to ensure that the study is conducted in accordance with the industry standard methodology and is inclusive enough in scope to adequately assess whitewater boating opportunities impacted by the projects using data, information and methodologies that are current.
3
Specifically, the licensee, in Section 10.0, Deviations from Requested Study, proposed a "Whitaker-type study" and further explains that "the requested flow study is unnecessary…".
I disagree with this deviation and the notion that the outcome and findings of assessment conducted can be pre-judged as the licensee has done here. Whitaker 2005 provides an industry standard methodology that is incremental, such that Level 1 is used to determine if a Level 2 or 3 analysis is needed. FERC should correct this misunderstanding in issuing a Study Plan Determination that follows Whiteaker 2005 and requires that a Level 2 and/or 3 study will be included in the study methodology if deemed necessary during Level 1 on each of the four river reaches identified in our study request and reflected in the study scope.
In Section 2.0, the licensee describes the goals of the study, which misrepresent the needs of the study to inform the FERC NEPA process as described in SD2. The goals of the study should be to evaluate flows for paddlers on four reaches of the river (Upper Gorge, below McKay Station, below Stone Dam, and Millinocket Stream), and not to solely "use existing information and paddler knowledge", as proposed by the licensee. It is inappropriate to list the goals of the study to discount the potential need to conduct a Whitaker Level 2 or 3 study if deemed appropriate.
The objectives of the study are also inadequate as they follow the language of the goals and do not indicate that a Level 1 Whittaker study may indicate that a Level 2 or 3 study is needed.
In section 5.0, the licensee describes Background and Existing Information. Regarding the Upper Gorge Below Ripogenus Dam, we believe that the licensee inaccurately describes this reach as "unsafe" and with difficult access, neither or which are correct characterizations.

The licensee is unqualified to make determinations of boating safety. The licensee cites numerous examples online of publicly available videos of kayaks, canoes and rafts using this reach, demonstrating both that this reach is safe to navigate at certain levels by experienced boaters, and that access is currently possible. This language should not be included in the FERC Study Plan Determination.

Specific to the West Branch Below Stone Dam, SD2 and the comments of AW, AMC and Maine Department of Conservation, Division of Parks and Public Lands on the PSP requested that the West Branch below Stone Dam be assessed to adequately evaluate the needs and opportunities related to this resource for whitewater boating and other recreation. In the RSP, related to Stone Dam in section 5.0, I believe the licensee is seeking to justify their lack of interest in following the Whitaker 2005 methodology by arguing that flows needed for such an analysis cannot be provided. I find this assertion to be unclear and inconsistent with other publicly available information related to the operating parameters of the Stone Dam.

Though the licensee claims that the inflatable flashboards that have replaced the old gate structures at Stone Dam prevent the licensee from conducting a controlled flow study in this reach, I find this contradictory to filings on this project to the Low Impact Hydropower Institute in their application and the reviewer's report in that docket (https://lowimpacthydro.org/lihi-certificate-167-millinocket-dolby-hydroelectric-project-maine/).

Regarding the Stone Dam inflatable structure, the LIHI docket notes that Stone Dam may be used to attain the 2,000 cfs minimum flow downstream of the Millinocket Project when the Millinocket project is offline. The LIHI docket notes that, "During periods of high seasonal flows or whenever abnormal conditions occur such that turbine flow [at the Millinocket Project] cannot be passed to achieve the 2,000 CFS minimum flow, the pneumatic rubber flashboard

4

system [at Stone Dam] is deflated to release flows in an expeditious effort. When this occurs, a two-minute siren warning is initiated and a safe flow of 200 CFS is released for fifteen minutes. Increases of 400 CFS per hour are made until either the required downstream flow is met, the elevation at Stone Dam falls to 459.45 FTMSL or the pneumatic rubber flashboard

system is
fully deflated. The ramping down of flows in the Back Channel is initiated once turbine
hydraulic capacity is restored or seasonal flows start returning to normal." Provided that this
information is accurate, it appears that Stone Dam can be operated in such a manner to assess
whitewater paddling with an on-water component as part of the study if deemed necessary after
Whitaker Level 1 study through single flow or multiple flow on-water study. This should be
corrected in the Study Plan Determination.
Though we appreciate that the licensee will "redouble" its efforts to locate available information
on this reach below Stone Dam, absent data being available that was collected consistent with the
Level 1 Whitaker methodology, I reiterate our request to follow the Whitaker methodology to assess whitewater in this reach through all three study levels as appropriate. It is
inappropriate for the licensee to argue that "sufficient information exists" as articulated in
section 10.0 when that information has not been located and may not be located during this
licensing proceeding for this reach.

RE: Comments on the Revised Study Plans for Ripogenus Hydroelectric Project (FERC No. 2572) and Penobscot Mills Hydroelectric Project (FERC No. 2458) from the Caribou and Chesuncook Lake Camp Owners Association and the Chesuncook Dam Camp Owners Association.

Dear Secretary Bose:

These comments on the Revised Study Plan (PSP) for the Ripogenus Project (P-2572) and the Penobscot Mills Project (P-2458) filed for Great Lakes Hydro America, LLC by Brookfield Renewable ("Brookfield") are submitted on behalf of the members of the Caribou and Chesuncook Lake Camp Owners Association and the Chesuncook Dam Camp Owners Association.

The two Associations represent over fifty camp owners with a significant and substantial interest in the relicensing of these projects. We have a long history, and deep love for and knowledge of, Caribou, Chesuncook, and Ripogenus Lakes, as well as a large financial commitment to our properties.

<u>Recreation Study - Inventory/Spot Count/Callibration Count/User Survey Forms Comments</u>

GLHA states, "To the extent possible, GLHA will also utilize recreation use and user survey data collected during the study to evaluate the potential relationship between impoundment water levels and recreation site use." To accomplish this lake levels of the day need to be recorded on all instruments. If not, the connection between water levels and recreational site use cannot be made.

We also support AMC and AWW in their request that the "scope of the study also include all formal and informal recreation sites as well as those recreation sites located near and adjacent to the projects, which would also expand the scope of the assessment as outlined in 4.1.5 of Scoping Document 2 ("SD2")." This scope is necessary to get a true understanding of the project's impact.

We also support AMC and AWW in their suggestion to strategically gather "input from a stakeholder working group, and key person interviews with organizational representatives from user groups, representatives of camp owners and other recreation related interests, such as

outfitters" as these audiences would "ensure that the interests of recreational users are well captured and not based solely on the opinions of the intercept survey respondents, which may or may not reflect the broader feedback and needs of that user group."

We appreciate GLHA including a Recreation Study. Following are items we request be included to ensure all necessary data is collected.

1. Inventory
    a. The inventory at remote sites needs to include distance from the site facilities to the water. For example, "Distance from fire pit to shoreline." Water level at the time of inventory will also need to be noted.
    b. The Boat Launch Facilities inventory needs to include the condition of the launch surface as the word "gravel" is too vague. Include a rating scale of the quality and usability of the surface.
2. Spot Count
    a. Data needs to be collated by lake. Millinocket and North Twin lakes have stable water levels throughout the summer recreational season and will have very different feedback and results than data from Ripogenus, Caribou and Chesuncook Lakes whose current water levels vary dramatically.
3. Calibration Count
    a. Data also needs to be collated by lake for the reasons stated above.
4. User Survey Forms
    a. Include an online survey, and direct mail surveys to camp owners on Ripogenus, Caribou and Chesuncook Lakes. These are the people who use the lake the most, know it well and upon which project operations have the greatest impact.
    b. Users of remote sites must be included in the surveys as this is a significant use of the waterways.
    c. Signage and introduction to the surveys needs to include language telling the respondent that the survey is part of the licensing process for a 30-50 year license. The survey respondent needs to understand the entire purpose of the survey.
    d. The survey needs to include questions about the impact of water levels. For example, include lake level with question 11.

<u>Boat Launch Useability Comments</u>

GLHA proposes to use SOBA'S "industry standard values" for useability of trailered boat launches, "including recommended minimum launching depth of three feet of water at the ramp toe, a maximum depth of one foot below the elevation of the top of the ramp, and a ramp slope not to exceed 15 percent; these guidelines acknowledge that less depth may be suitable for some boats (SOBA 2006)." Chesuncook Lake is the third largest lake in Maine, known for the strong winds that stretch over its 20 plus mile length. As such, the boat launch will need to be able to

accommodate the larger boats necessary for safe navigation on Chesuncook, Caribou and Ripogenus lakes. These boats are at least 17 feet long and often as long as 25 feet. SOBA guidelines also speak to boat launch substrate. The Chesuncook Lake boat launch is currently described by GLHA as "gravel." In their "Gravel Roads, Maintenance and Design Manual," the EPA describes, "Gravel is a mixture of three sizes or types of material: stone, sand and fines," including for road construction, "The base course requires 100% of the material to pass a 1 inch sieve, but allows up to 20% of the stone to be retained on the 3/4 inch sieve." The current Chesuncook Dam boat launch substrate includes rocks at least 4-6 inches wide, with some over a foot or more. This assessment needs to include size of rocks at the boat launch and a determination if gravel is even an appropriate material given wave and ice impacts on the site.

Aesthetics Study Comments

In the Aesthetics Study proposal GLHA acknowledges the visual significance of the project waters. They refer to an Aesthetics study done in 1990. Although the mountain views and wilderness beauty of the area remain solid, the shoreline and water views are very different than in 1990 when water levels were more consistently stable than under current operation. GLHA identifies Objectives of the study as: 1.Document views of Project lands and waters, and the surrounding landscape, from the Project recreation sites and 2. Document views of Project lands and waters, and the surrounding landscape, from other KOPs where the Project is frequently viewed by the public. They further identify "Visual resources related to water include the flatwater expanses of the Project impoundments as well as portions of the West Branch of the Penobscot River and Millinocket Stream." Indeed, these are important objectives and visual resources, yet, more is needed.

An objective that moves beyond documentation and evaluates the connection between lake levels and aesthetics needs to be included. To meet this objective, specific sites of visual importance within Ripogenus, Caribou and Chesuncook Lakes, need to be identified, with photos and video recordings at these sites at different water levels. These are the locations impacted by drastically changing lake levels. Using the same sites identified in a 1990 study does not address the impact of water levels on aesthetic qualities of a location.

Current sites identified for the study are not adequate to meet the suggested objectives. For example, the Abol Bridge site is an iconic view of the largest mountain in Maine, and the end of the Appalachian Trail. This location has been photographed thousands of times. Other than seasonal changes, the visual is always the same. Abol Bridge views are not impacted by water levels. The sites being studied need to show visual variation at different water levels.

The Aesthetics survey also needs to include a question about shoreline and water levels. The distant mountain views are always stunning. It is the shoreline that becomes visually unappealing at low water levels.

These nuances of the area cannot be defined by those who don't spend considerable amounts of time at the project sites. For this reason we support AWW and AMC in their suggestion to form "an aesthetics study working group to further identify KOP's in the project boundary and in areas affected by project operations. This working group can also work with the Licensee to further refine survey instruments and data collection methods such as intercept and online surveys, as well as to engage with the licensee in reviewing the study data to assist in analyzing this data to be included in the Initial Study Report."

Socio Economic Study Comments

GLHA referred to the Socio Economic Study proposed by the Penobscot Indian Nation as lacking a nexus. The nexus is the direct correlation between the project's waters and surrounding land and the socio-economics of the region. In the past relicensing, the region was dependent upon Great Northern Paper Co., which no longer exists, and which the dam generated power directly for and thus supported 2500 regional jobs. Any dam relicensing's true nexus is a chance to evaluate the necessary balance between the use of a public resource, the water that the people of Maine own, with the needs of a private entity and the public good. Clearly the economics of the region has changed dramatically and thus the existing balance has changed. A study is needed to determine if the economic drivers of the outdoor recreation industry and the water needs to support that industry now outweigh the economic benefit of unrestricted power generation and thus a need to recalibrate the new permit to meet those needs. The outdoor recreation industry within the project boundaries clearly includes whitewater boating and fishing on the river. It also includes boating and fishing on the lakes as well and the time and investment people spend at their waterfront properties.

Additional Study Request Comments

There are other studies requested by other stakeholders important to an overall assessment of the needs, protection and potential of project lakes, rivers and communities. A Whitewater Boating Assessment Study is proposed by AMC and AWW using industry standard methodology with an inclusive scope. Industry standard and a broad scope are necessary for all studies within the licensing process. GLHA refers to industry standards in their study proposals, the same should be offered to other agencies. The National Marine Fisheries Services proposes the following studies: 1) Indicators of Hydrologic Alteration Model; 2) Project Effects on River Temperature in the West Branch; and 3) Future Flow and Water Temperature Study. NMFS, a branch of NOAA, mission includes "Productive and sustainable fisheries and healthy ecosystems" This agency understands science and industry standards and should be given the tools, in this case, the requested studies, necessary to complete their mission. The same is true for requests from TU

and the Maine DEP for a fish assemblage study. Our anecdotal evidence also suggests strong merit in Ed Spear's request to study zooplankton and the effects of severe lake draw down on the smelt population. GLHA notes that Maine IFW recognizes an overpopulation of salmon but IFW at the same time closed Chesuncook and tributaries to the taking of smelt. This strongly suggests concern for the smelt population. These experts, and all agency representatives, are experts in their fields working for the benefit of the project's ecosystems, fish and wildlife, as well as all the people who use and enjoy the area. FERC needs to give their input the strongest consideration and require GLHA to perform the requested studies.

Thank you for considering our comments.
Respectfully,

Bill Houston

The Ripogenus and North Twin Projects P-2572-133 and 2458-247

RE; Revised Study Plan Comments Filed March 23, 2022 and a Critique of the June 8, 2021 Preliminary Application Document and Notice Of Intent

The Licensee's continues to refuse and refute the need for critical fish, angler, aquatic communities and lake level management studies. As the licensee knows from its sponsorship of multiple studies of the Magpie and Batchawawa Rivers (see Marte, Smokowoski and many others), peaking operations have significant impact on fish and aquatic communities. These and other studies provide much needed peer-reviewed information necessary in evaluating fisheries and aquatic communities relevant to the licensing of two major projects. In addition, robust field studies are needed to define the current status of fisheries and aquatic communities. The March 13, 2022 Revised Study Plan (RSR) submission is a continuation of unsupported claims and the licensee's apparent desire to avoid any study that would demonstrate the diasterous impact of current flow and lake level management. In refuting study requests, rather than citing much needed empirical aquatic and fisheries data or peer reviewed literature, the licensee cites legal precedent(s). This is simply their opinion. The Licensee's objectives are now clear, delay the licensing process as long as possible. Today's license is much better than any new license. Base the licensing process on arguments of legal precedent rather than biological fact. Clearly, this not what the NEPA foresaw.

Preliminary Application Document (PAD)

When I first Read the Preliminary Application Document (PAD) I was shocked by the omissions and misstatements contained in the fisheries and aquatic communities sections. Had a high school student submitted the PAD as a tenth grade history paper, it would have failed. The authors apparent unfamiliarity with data from impoundment, river reaches and tributaries is telling. The PAD is a poorly organized attempt to rehash 40 year old data and develop conclusions that can not be supported by science. The following paragraphs briefly review the PAD flaws that need to be corrected to make the record accurate.

The most pointed of the Licenses' comments is that operations have not changed and everything is as it was in the 1980s and 1990s. They support that contention with 35 plus year old fisheries and aquatic data and then demonstrate that operations have changed in their March 23, 2022 submission of ten years of flow and elevation data. Current operations in no

way duplicate flows and lake levels observed during Great Northern Paper's Rule Curve operations and relatively stable base flows.

2.1 This section appears to be the licensee's opening statement implying that they want a fact based license. "*Search for Existing, Relevant, and Reasonably Available Information In support of preparing this PAD, HDR, on behalf of and in conjunction……..".* This has not happened.

One of the more telling indications of effort to find facts is found in sections 5.4.2 and 5.4.1. "*There are no flow gages immediately upstream, within, or downstream of the Ripogenus and Penobscot Mills Projects,".* USGS has had a flow gage on the North Branch of the Penobscot River for 20 years. Tributary inflow is readily available by "Googling" USGS then Maine, the North Branch of the Penobscot River.

Further evidence of providing miss-information is found in 5.3.4.*1 "The Ripogenus Project is used for hydroelectric power generation, recreation, flood control, and wildlife and aquatic habitat. As described in Section 4.4.1, the Ripogenus impoundment is used to store excess runoff from spring snowmelt and rainfall (e.g., flood control) for the release of water downstream at a controlled rate. <u>This creates stable year-round flows downstream</u> to provide a sustained load of energy and provides fish habitat, recreation*….." <u>*(emphasis added).*</u> MeDIFW questioned this statement it is October 8, 2021 filing, "**MDIFW observed on several occasions in the winter and summer of 2021 that the Licensee was indeed running in excess of 3,000 cfs when lower flows were required by the license;"** The Licensee's March 23, 2022 filing of daily flow records demonstrates the ridiculousness of the "stable year-round flow" comment. There is nothing "stable" in a peaking operation.

Page 5-93 "*Seven tributaries to the Ripogenus impoundment support landlocked salmon spawning runs, including the upper West Branch*". This statement is unfounded and misleading. While juvenile salmon were occasional found in many Ripogenus Project tributaries, there is no evidence of significant spawning or juvenile production in any tributaries other than Ripogenus and Ragged Streams, the upper West Branch and Caucomgomic Stream (where Caucomgomic Lake fish seem to dominate). Cuxabexis Stream has a very limited area (perhaps 500 square yards) of high quality spawning and nursey area.

Page 5-93 "*Small spawning tributaries also exist in the West Branch from McKay Station downstream to the North Twin impoundment, but most salmon spawning occurs in the West Branch itself*." Only Kadahtin Stream provides any spawning <u>and nursery</u> area and due to the relatively short stream length containing salmon habitat, reproduction is limited.

Page 5-93 "*There are no tributaries or riverine spawning habitat between North Twin Dam and Quakish Lake*." This statement is incorrect and this error provides the licensee an opportunity to avoid statutory requirements. During redd survey years (circa 1988-1989), <u>15-20 salmon redds were observed below the "Green Bridge"</u> (Rt 11) downstream to the confluence of Quakish Lake. While young-of-the-year (YOY) salmon were collected in riffle areas, nursey

habitat for this life stage is limited (Vol II E 3.2-42). The PAD' omission of salmon spawning and nursey areas in the West Branch downstream of the North Twin Dam is a serious error. The issue of salmon spawning and reproduction "brings into play" the Maine Department of Environmental Protection' s (MeDEP) statutory requirements e.g., "designated uses" and "naturally occurring" and the need for supplementary production from a watered West Branch Channel (AKA the Back Channel).

The PAD notes that the North Twin tailwater fishery is generally support by hatchery fish, outmigrants from the Upstream Impoundment. MeDIFW noted that salmon stocking was discontinued 2017, present management of the North Twin Impoundment is through natural salmon reproduction. The 1992 GNP license application states that 80 % (EIS 3.5.1.1) tailwater salmon were of hatchery origin. This raises the questions as to how North Twin tailwater recruitment (of adult salmon) needs are presently being met. The limited tailwater juvenile salmon population has been further reduced by the facilities peaking mode. The impacts of present operations on juvenile salmon production downstream of the North Twin Dam can be mitigated though the watering of West Branch Channel. The proposed fish assemblage study should define the status of this tailwater fishery

Page 5-95 "*Lake trout are distributed throughout the Ripogenus, North Twin and Millinocket Lake impoundments*". There no lake trout in the Ripogenus Impoundment and none have been observed in the last 20 years.

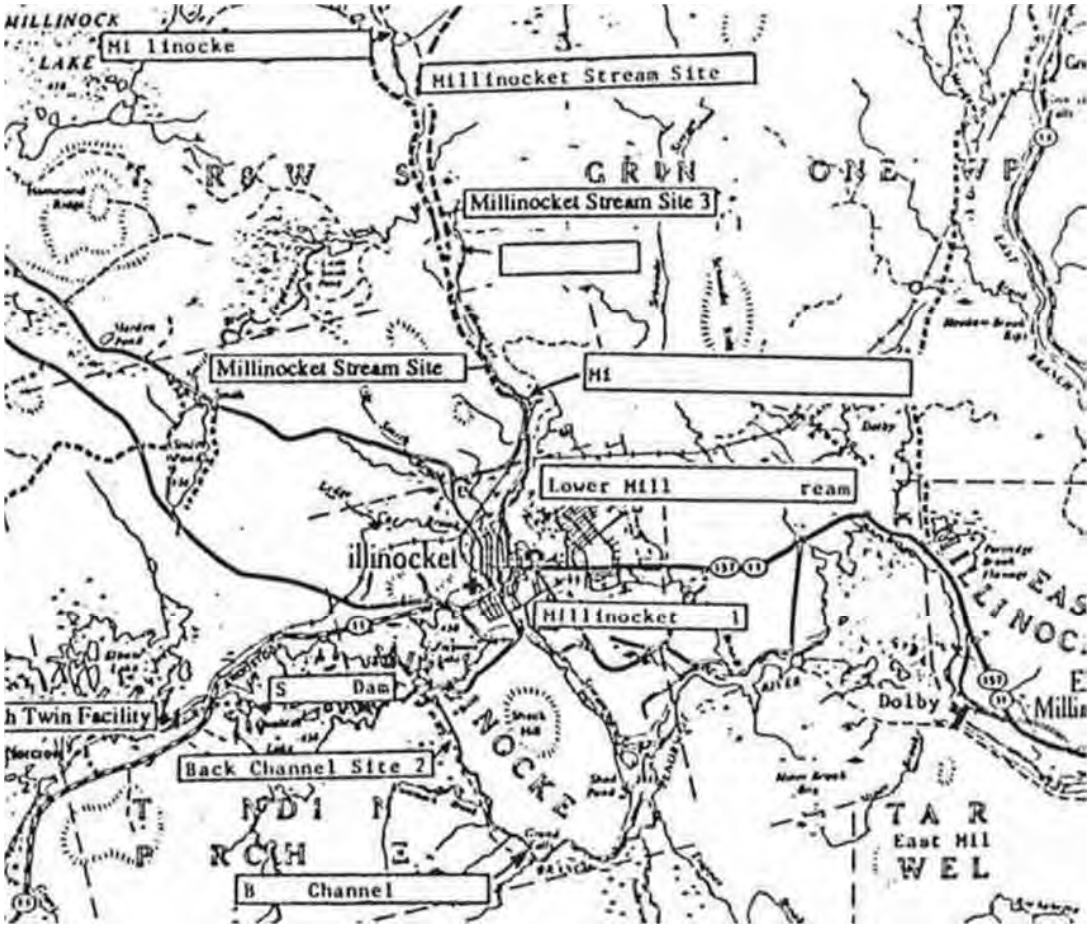
Page 5-97 "*Rainbow smelt populations are substantial in the Ripogenus, North Twin, Millinocket Lake, and Dolby impoundments".* While this statement was correct 30-40 years ago, current Maine Department of Inland Fisheries and Wildlife (MeDIFW) studies demonstrate that smelt populations are in serious decline in the Ripogenus Impoundment and West Branch below McKay Station.

Page 5-106 - "*Nineteen tributaries feed into the Ripogenus impoundment that provide habitat for brook trout, landlocked salmon, rainbow smelt, and other native fishes (Figure 5.1-2). Seven of these tributaries (Ripogenus Stream, Duck Brook, Cuxabexis Stream, Caucomgomoc Stream, Little Scott Brook, Upper West Branch, and Ragged Stream) have historically produced enough juvenile landlocked salmon to support a wild, self-sustaining fishery*". In yet another example of the lack of reviewing basic data or a map, Duck brook is not a tributary of the Ripogenus impoundment although it does flow into Ripogenus Stream. The suggestion that rainbow smelt inhabit tributary stream is miss-leading however smelt did spawn (during study) years in many, but not all impoundment tributaries. All smelt spawning occurred within (flow) transition zones within the project boundaries

Page 106 *The Upper West Branch of the Penobscot River is the most important and productive of the Ripogenus impoundment tributaries with regards to spawning and adult habitat (GNNC 1991a). The salmonid fisheries in the Upper West Branch reach are primarily supported by fish from the Ripogenus impoundment population, as opposed to upstream water bodies. The reach*

*provides spawning opportunities for salmon, but also supports its own robust fishery (emphasis added). The river fishery in this reach tends to reflect the status of both populations (river fishery and impoundment fishery) with regards to health and abundance (GNNC 1991a, FERC 1996).* There is NO "river salmon fishery" (emphasis added) i.e., year-long salmon population, the Upper West Branch fishery is entirely supported by Ripogenus Impoundment salmon. The use of salmonid is misleading and incorrect as there are no brook trout or other salmonid species.

Page 5- 109 *This life history is unusual in that landlocked salmon generally spawn in tributaries but rear and grow in larger lakes. The West Branch, however, provides lacustrine adult habitat in the large deadwater areas and pools, and ample spawning and parr nursery habitat in flowing reaches. Necessary forage opportunities are provided to this reach via smelt drift from Ripogenus impoundment*. This statement reflects conditions in the 80s and 90s, current MeDIFW information suggests that smelt drift is poor, at best. The licensee should prove this statement or remove all references to smelt drift.



Page 5-110 "*During the previous relicensing effort, the Licensee proposed to provide stable minimum flows from McKay Station into the West Branch to promote landlocked salmon spawning and egg incubation. As such, pursuant to License Article 402, GLHA provides landlocked salmon spawning flows of at least 1,422 cfs (or inflow, but not less than 1,300 cfs) from October 15 to November 15 and incubation flows greater than 1,422 cfs (or the spawning flow established for that year) from November 16 through June 7. These flows were developed to prevent exposure and desiccation of salmon redds and enhance overall reproductive success (FERC 1996). Further, GLHA implements automatic, short-term "outage" flows of 400 cfs downstream of McKay Station during station outages as a temporary means for protecting aquatic habitat in downstream reaches of the West Branch. Stable flows resulting from water management at McKay Station help to maintain constant, high quality flow conditions downstream. Specifically, the water management regime provides high quality habitat, abundant smelt drift, and above average water quality".* While these statements were correct in 1996 this is not the situation now "as *maintain constant, high quality flow conditions downstream"* has been replaced by peaking operations and daily dewatering of critical fish and aquatic communities habitat.

Page 5-110 "*As part of the flow improvements made in the West Branch during the previous relicensing, GLHA developed and constructed landlocked salmon nursery and spawning habitat at the Holbrook Side Channel, which is about 0.8 miles downstream of McKay Station. The project created approximately 14.5 acres of stream habitat for landlocked salmon and other fishes in the Holbrook Side Channe*l." The 1,300 foot Holbrook Side Channel does not provide 14.5 acres of stream habitat. However, when flow is provided, this area supports high quality salmon nursery habitat.

**5.3.4** "*During the previous relicensing of the Projects, the Licensee identified and prioritized water uses and performed operations modeling to create a plan to meet generation requirements, environmental enhancements, and mitigation measures. Based on the modeling*

*results, the Licensee developed a Water Use Plan (WUP) that identified proposed operations of the Projects and that was designed to balance and manage multiple competing water uses (e.g., power generation, recreation, fisheries, minimum flows, flood control). This WUP was used as the basis for the operational requirements for the Projects as indicated in the 1996 FERC licenses, as amended, and as described previously in Section 4"*. The Licensee no longer follows the WUP, thus this statement in misleading. There is zero indication that the licensee considered any non power objectives during 2021-2022 and in other years.

5-131 "*STUDY SITES An IFIM study was conducted using a transect-based Physical Habitat Simulation (PHABSIM) hydraulic model at 2 sites: one site located above Grand Falls and another located below the falls*." This statement is incorrect and misleading. As the map indicates, one study site was a few hundred yards below Stone Dam and the other ABOVE Grand Falls. This error is significant as it goes to the study team's selection of habitat types e.g., parr and adult, parr and fry is relevant to future study goals and site selections.

5 -212 "*Additionally, there are multiple commercial recreational opportunities outside of the rafting industry. The Big Eddy Campground (formerly known as Pray's Cottages) provides fee-*

*based camping and lodging options along the West Branch downstream of McKay Station"*. This is incorrect, Pray's Cottages were located about a half mile downstream of Ripogenus Dam and 400-500 yards West of the Upper Gorge. The Big Eddy Campground, located 1 ½ mile downstream of Rip Dam was owned and operated by Bunny and Peter Pray and sometimes referred to as "Pray's Big Eddy Campground" and is now operated by the Chewonki Foundation.

Page 6-4 "*Baseline Fisheries -West Branch (below McKay Station) Potential effect of Project operations on West Branch fisheries – current baseline • Significant amounts of information/data on West Branch fisheries already exist, as fisheries data were collected during the last relicensing and has continued to be collected by the GLHA and MDIFW. • The existing fisheries data are sufficient to characterize the existing West Branch fishery. • As there have been no changes to Project operations, there are no expected changes or impacts to West Branch fisheries*." This opinion is often repeated. There is no science to back it up as fisheries data has not *"continued to be collected by the GLHA and MDIFW".* As noted multiple times, these statements are out-dated as project operations have undergone dramatic change, from relatively stable bass flow operations to peaking operations.

Millinocket Stream. In my December 6, 2021 filing I noted the Licensee's failure to reference the circa 1994 Millinocket Stream eel weir. While the operator, Mr. Rodney Corvieau, may be able to supply more accurate totals, my recollection is that the catch was several thousand pounds. Significant in any event. At the time of my filing, I assumed this omission was just another example of poor research, mea cupla. In reading the Recent Revised Study Plans it has become clear that the licensee has little interest in science and that all filings are based on developing a "legal setting". Any acknowledgement of a significant eel outmigration from Millinocket Lake would provide a base for downstream eel passage requirements requested by multiple agencies at three downstream facilities. At the very least, FERC should require that the licensee acknowledge significant eel outmigration down Millinocket Stream. References to the eel weir would be recorded on Millinocket Stream Great Northern Paper's creel census forms.

In summary, after reviewing the PAD and RSP it has become obvious that the licensee's intention is to avoid, at all costs, fisheries and aquatic communities studies that would likely demonstrate the continuing impact of peaking operation and the resulting (lack of) lake level management. In filings of January 27, February 12, and February 22, 2022, I provided comments on the improvised fish and aquatic communities of the Ripogenus and Penobscot Mills Projects. Each filing was accompanied with a preponderance of supporting data from peer reviewed journals. It should be noted the licensee did not challenge the science but continued with legal arguments.

**Comments on the licensee's Revised Study Plan.**

Scoping Document Two; Study Plans Resource Issues; 4.1.2, Water and Aquatic Resources

Scoping Document two (SC-2) was developed following comments provided in response to Scoping Document one (SC-1). In SC-2 FERC stated the issues, raised by the stakeholder, would

be addressed. Section 4.1.2 issues most relevant to fisheries and aquatic communities are listed below.

- 1) "Effects of change in historical project operations (based on generation records) on baseline flow patterns in the West Branch, and how such changes may effect aquatic resources in the vicinity of the projects and the West Branch including the effect on fish migration timing and passage in the mainstem of the Penobscot River."
- 2) "Effects of continuing to operate the projects under the existing Water Use Plan and alternatives to that plan …."
- 3) Effects of Project operations on temperature and DO……
- 4) "Effects of drawdowns and fluctuating lake levels on Ripogenus, North Twin and Millinocket Lake Impoundments on littoral habitats and associated aquatic communities…"
- 5) "Effects of Ripogenus Project operations on Lake Whitefish populations in the Ripogenus Impoundment."
- 6) "Effects of Project operation on aquatic insects, crayfish, and other macro invertrabrates in the project impoundments and the West Branch ….."

The Revised Study Plan fails to address many of the stakeholders study concerns mentioned in SC-2 and when it does, only in vague terms with generally unspecified methods. In addition, the Licensee fails to address most of MeDIFW's, the *lead state fisheries agency in Maine,* study requests. The answers to issues raised during SC-1, Sc-2 and by MeDIFW should be though data collections and analysis rather a literature review.

The licensee continues to rebuke virtually all fisheries related study requests not mandated by the agencies**.** For the fish communities, despite the Licensee's March 23, 2022 filing of flow records covering 10 years of flow and elevation data that demonstrate hydro peaking, the licensee continues to insist that "nothing has changed". The licensee argues that 35-40 year old data remains valid. The licensee has basically rejected all studies not included in the PAD. So why is the licensee repeating West Branch channel (AKA the backchannel) and upper Gorge flow studies or the North Twin Impoundment salmon spawning "obstruction" study? In all three cases, the rocks, ledges, and gravels have not changed. The results are known. The answer is obvious, these three studies are "safe", other than North Twin Impoundment salmon collected for radio tagging, no fish collections. There will be no danger that the collection of salmon or trout will provide "new" data that demonstrates reduced growth, abundance or distribution in the lacustrine or riverine project waters.

The Licensee's stock responses to study requests are, "fails to meet study criteria", "MeDIFW didn't request it", and as "being redundant or outside the scoop of the NEPA process". However, the final choice of studies is not up to the licensee rather FERC and FERC staff. As mentioned before, the licensee is assuming a negotiation posture and forming legal positions heading to the end game.

**5.5 Ramping Study to Determine Appropriate Rate of Flow Change below McKay Station**

*"Mr. Ed Spear requested a ramping study to determine the appropriate rate of flow change in the West Branch below McKay Station. Specifically, Mr. Spear requests that a study should include an independent, peer-reviewed water management plan that includes an up and down ramping prescription protective of sensitive aquatic insects, namely hydropsychid caddis and salmonids*."

*"GLHA is not adopting this study as requested. However, GLHA believes that information collected and reported from other proposed studies, such as the Historical Operations Data Assessment Study, will provide information on how the Ripogenus Project has been operated, including flows provided by McKay Station. …* followed by addition verbiage and tabular flow information too often repeated *…..Additionally, field work to be performed in the West Branch below McKay Station for other studies, such as the Wood Turtle Survey, will provide additional information regarding flows in the West Branch in relation to aquatic resources".*

<u>My Response</u>

Both of the above referenced flow and water managements requests are both reasonable and common. Many western water users have "modern" water management plans as well as ramping guidelines. In fact, MeDIFW in its Ocotber 8, 2021 comments stated "*the literature is replete with examples of the detrimental impacts on the riverine fisheries and aquatic communities from rapid changes in flow, and that the literature indicates that flow changes of less than 25% per hour (ramping rate) can mitigate impacts from peaking power, we request flow records to evaluate the frequency of flow changes that exceed 25%".* MeDIFW also requested; "fine tune the water management for the Ripogenus Project Water" in its October 8, 2021 filing. Brookfield's upstream Storage Project license contains 401 WQC ramping prescription at Caucomgomic Dam and Brookfield facility on the Magpie River (Ont, CA) is operated under ramping guidance. Ramping rate studies are often required and ramping rates are a normal license conditions of FERC licenses. The measurement of river elevation changes over flow and time are not expensive and for the West Branch below McKay Station would only require two or three study sites. It is difficult to understand the licensee's objection to this MeDIFW simple study request.

The long awaited and recently provided ten years of flow and elevation records are of no use when considering (rapid) flow change over time. Historical information shown in hourly increments is useless. In the case of ramping, past practices are irrelevant, in the case of flow change, the licensee was following licensed flow prescriptions. The question is the <u>*future*</u> rate of flow change over time, *hydropsychid caddis and salmonids* need future protection.

The licensee failed to mention what other studies would provide flow change data. While I have seen wood turtles on the bottom of the Miramichi River (NB, CA) while snorkeling, it is difficult to imagine a wood turtle study, even one preformed with scuba gear, as contributing useful ramping information. The Licensee needs to clarify how a particular study will be modified to

provide flow change data. Simply stating that a commonly required study is not needed, does not refute the need for a particular action.

**Section 6 Studies not Adopted**

**6.6 Fish Assemblage Study**

**The Sebago Lake Chapter of TU requested a fish assemblage study of each impoundment and riverine reach in the Ripogenus and Penobscot Mills Project areas speculating the following:**

My Response

In an earlier filing, MeDEP requested a fish assemblage study of the Ripogenus impoundment. In an earlier filing, I recommended collections of salmonid species from all project waters, thus I fully endorse MeDEP's and TU's requests. The MeDEP request referenced the West Branch below McKay Station and information on salmonid growth and abundance of one of Maine's premier riverine reaches is desperately needed. Forty year old data collected during periods of relatively stable flows has no value when present operations are now in a peaking mode and "rule curve" lake management no longer exists.

I am unsure of what a fish assemblage study involves. In my view, trap netting, electrofishing, hydro acoustics along with a few minnow traps will provide the necessary information. Lethal collections, wide mesh gill netting, is a choice of last resort and should be avoided. In order to identify the status of the Ripogenus Impoundment rainbow smelt population, the key element of the Ripogenus-West Branch salmonid fisheries, trawls, tows, hydro acoustics and fine mess vertical gill nets could be considered.

While implied, I saw no direct reference to Lake White Fish (*Coregonus clupeaformis*). This species was listed in Scooping document -2 and declining populations are the subject MeDIFW's concerns and goals. Thus, inclusion of Lake whitefish in a fish assemblage study is important.

**6.7 Creel Survey Study**

"*By letter dated November 9, 2021, Mr. Edward Spear requested GLHA conduct a creel survey on the West Branch of the Penobscot River. Mr. Spear requests that GLHA duplicate the 1978 study plans developed during the previous relicensing effort. GLHA acknowledges that creel survey data were collected and utilized during the previous relicensing, but it important to note that the 1978 study plans referenced by Mr. Spear were developed for the purpose of licensing and constructing a new dam ("Big A") on the West Branch of the Penobscot River downstream of the Ripogenus Project. Although these study plans were not developed for relicensing purposes, the resulting creel survey data were nonetheless utilized for relicensing due to the extensive fisheries data collection efforts associated with the Big A licensing effort, which preceded and led up to the Ripogenus Project relicensing.*

*While GLHA does not believe that creel data are directly applicable to FERC's NEPA analysis, MDIFW periodically conducts its own creel surveys, and plans to continue doing so. GLHA is not proposing the study request for the following reasons.*

***• Study request is not necessary because existing information is sufficient to answer the questions posed (Study Criteria No. 4) and/or the study request is an attempt to search for the existence of a "nexus" (Study Criteria No. 5)****:*

*As noted above, if a study request is an attempt to search for a Project effect, it does not meet FERC's criteria and it is not enough to speculate that a problem may exist or that the "evidence" of a problem is simply based on a "prediction based on opinions."*

*GLHA notes also that no federal or state fishery agency requested such a study, including MDIFW. In fact, MDIFW (letter dated October 10, 2021) explicitly states that:*

*"MDIFW concurs with the Licensee that there is an extensive history of inland fisheries studies associated with the Ripogenus Project completed in preparation for the 1996 license, and these studies need not be duplicated unless there are identified data gaps, or changes in operation that may impact the fisheries resources."*

*"MDIFW did not request creel surveys in their February 22, 2022. Given that the lead state fisheries agency in Maine has not requested creel data as part of the relicensing effort, GLHA does not believe this study is necessary."*

My Response

The licensee seems to take issue with the reasons for the 1979 Big A creel survey, implying the reason for the study, in some way, invalidates the results. In any event, the licensee overcame its concerns and continues with the old argument that 35-40 year old data are relevant and there are no needs for "new studies". The lack of current information is more than a "data gap", it is a black hole. The licensee continues with misrepresentation of the facts. "MeDIFW *periodically conducts its own creel surveys"* is simply incorrect in regard to Ripogenus and Penobscot Mill Projects riverine reaches. There have been no surveys of riverine areas in 35-40 years. Had MeDIFW conducted angler, fish collection or electrofishing surveys of West Branch riverine reaches, we would have seen the results. However, there have been winter surveys of both the Ripogenus and Penobscot Mills impoundment anglers. The Ripogenus survey is the most revealing as the adult salmon population has collapsed as well as the (juvenile) rainbow smelt population(s). Smelt "drift" though McKay Station provides a clear nexus to the downriver salmonid fisheries. The current status of all project tailwaters fisheries, including angler use and catch is relevant to the NEPA process as well as the Maine Department of Environmental Protections' "designated uses" and "anti-degradation" statutes.

The licensee claims that study criteria No 4 ***"there is no evidence of a problem"*** has not been met. A number of West Branch anglers have filed comments that indicate an opposite view. The Ripogenus salmon population is in decline. MeDIFW's recent smelt drift net collections below

McKay Station, while preliminary, indicate a precipitous decline in juvenile smelt, the principal salmon forage item. Beginning in 2019, I volunteered my service to the Greenville Regional office to collect lengths and scale samples from West Branch salmon. I fished at Nesowadnehunk Deadwater and Holbrook Pool, large salmon (>18 inches) were few. During my 25 year career of studying West Branch salmon, I measured and weighed hundreds of salmon. The fish I collected (approximately 150) during the 2019 – 2021 seasons were smaller in both size and weight than those of the 70's. 80's and 90's

Poor salmon growth, fewer smelt and angler complaints, how much more evidence of a problem is needed? This study proposal is not a result of speculation and it meets the change in project operations criterion. Additionally, how can MeDIFW possibly know that no studies are needed when all West Branch fisheries and aquatic communities data are, at a minimum, 30 years old? The MeDIFW position contradicts the draft 2021 Salmon Management Plan and makes NO SENSE.

Typically, the licensee is incorrect in regards to support for studies I have presented. The USFWS endorsed my study proposals in its February 22, 2022 filings. Also, to correct, the often inaccurate responses of the licensee, I asked for a creel survey, and suggested it follow the 1978 creel survey designed by MeDIFW and Great Northern Paper. When the Big A license application was withdrawn, the ongoing West Branch (in the tailwaters below McKay [and downstream to Pockwockamus Falls] and North Twin Stations) creel surveys were modified to meet relicensing goals and continued.

Demonstrating once again that the licensee has no idea of fish and aquatic resources management the licensee states "angler behavior" is not an action FERC can regulate. "Angler behavior" is a "term of art". The West Branch below McKay Station currently is managed by restrictive harvest regulations, thus the thought or idea of any "outside" management e.g., FERC, has no bearing on harvest of fish species, salmon in this case. Angler behavior simply refers to a number of variables; fishing gear (fly fishing, lure fishing, bait, etc.) and area (pool, rapids, etc.) is well as time (mornings, evenings, nights), season (spring , summer, fall) method (boat, drift boat, wade, or shore fishing). It is well known, that MeDIFW in conjunction with public hearings set Fish and Wildlife laws. To suggest otherwise seems to imply a naïve audience. However, MeDIFW can not manage its riverine fisheries resources without data. FERC and MeDEP also require current data to create licensing conditions that will ensure the process of balance between impoundment and riverine users e.g., boaters, anglers, campers, camp owners, sightseers and hydropower. Examples of such reasonable acts would be the requirement of higher minimum flows and stable base flows and stable impoundment elevations for all riverine and lacustrine areas.

Finally, the Licensee states that it may be in possession of new creel survey data. As I previously stated, I was unaware of any creel survey activity in the study areas, however I was aware of volunteer angler survey boxes. While I saw no licensee request for data, suddenly "current" MeDIFW creel survey data has become available. These are potentially important areas of

information and I hope the level of intensity and effort duplicates the effort used in the 1992 licensing. In any event, I welcome the licensee's change in strategy. *"GLHA has proposed to compile and synthesize fisheries data in the Ripogenus Project area, including any recent creel survey data that may not have been discovered during PAD development."* How can this happen after the license claim that they conducted an exhaustive search? "*…. GLHA, has undertaken an extensive effort to identify and review existing, relevant, and reasonably available information related to the Projects*" (PAD)? The 'open water' fishing season has been closed for six months, this can hardly be "new" information. Presumably the "new" creel survey information is from angler survey boxes, however "survey boxes" do not provide "creel survey data" in the true sense of the term. A creel survey is normally collected by a paid individual interviewing the fishing public. This passive survey box method depends on voluntary information and is known to be biased (technically called prestige bias, as successful anglers are more likely to fill in survey cards than angler who were unsuccessful). One would suspect that survey box information is even more biased as they were located near areas where angler and fish were concentrated. *The collection of these data will allow for a better understanding of angler success in the West Branch downstream of the Ripogenus Project*. It is impossible to agree or disagree with the licensee contention without first examining these data. Presumably these "new" data, if in fact they are from volunteer angler survey boxes will be provided in reviewable form. Thus, I hope these data are sorted by box location, fishing site, and date.

Regarding future creel surveys, it should be noted that each MeDIFW regional office each has hundreds of lakes and many hundred miles of streams and rivers to manage. MeDIFW offices have small staffs and many different mandates to follow. Their pride and effort in attempting to conduct exhaustive creel surveys in remote locations is a credit to their commitment to the resources. The 40 year old Great Northern Paper (GNP) creel survey data provided by the licensee was the result of 60-80 survey hours a week (see GNP creel survey records) during peak fishing seasons. Anglers fished early, many stayed well into the evenings, the effort to interview or enumerate anglers fishing in the McKay Station – Pockwockamus Falls river section is demanding, Even more demanding given the additional travel time between Greenville and Enfield offices and the Big Eddy or Debsconeag Deadwater. Future creel survey data collection should be robust rather a "snap shot" taken over a partial fishing season. Should MeDIFW attempt this difficult labor-intensive task, FERC should require the licensee to provide support.

If MeDIFW had important information, it should have been presented as preliminary yet to be analyzed data in the October 8, 2021 filing, to be later shared with the stakeholders. It would have also been more appropriate for MeDIFW to post any new data via an E-library filing rather than first consulting with the licensee. I understand anglers but I do not understand this process.

**6.8 Study to Determine Status of Impoundment Zooplankton Population and its Relationship to Larval and Juvenile Rainbow Smelt**

**Study request constitutes basic research and/or is not likely to inform the development of license conditions (Study Criteria No. 5):**

My Response

For lack of a better defense, the licensee rejects this study as **(Study Criteria No. 5)** basic research, despite referencing historic (1980-1984) zooplankton collections in the PAD's supporting documents. This simply is the licensee's opinion. This study request will provide the answers to most of the problems associated with the Ripogenus Impoundment and the downstream salmon fishery. The likely results of data provided by this study is that FERC/MeDEP will be able to prescribe enhancement and mitigation measures.

While the origin of Rainbow smelt is not important to the issue(s) concerning the Ripogenus impoundment smelt population, the Licensee continues to struggle with fisheries facts. According to the PAD (MDIFW 2021), rainbow smelt are an introduced species in the Project area, this is likely correct. However, in A-16 smelt are identified as an indigenous species, I believe this is probably incorrect. What I am certain of is that both propositions can not be correct. As this goes to "naturally occurring", the licensee needs to clarify which "smelt designation" is correct.

MeDIFW has identified a Ripogenus adult salmon population in collapse and linked it to smelt abundance. I agree with MeDIFW's assessment of the adult salmon population's decline but adamantly disagree as to the cause. Without current smelt and plankton data, any statement of the root cause of the reason(s) the Ripogenus salmon adult salmon population decline remains unknown. The preponderance of information found in the literature points to plankton as being the cause of (juvenile) smelt population(s) declines. If such a study designed to collect, enumerate and identify existing Ripogenus phyto and zooplankton communities and smelt populations is considered basic research, then what criterion/criteria separates "basic research" from routine monitoring? This study request involves inventorying the Ripogenus impoundment's phyto and zooplankton communities and smelt populations, a simple description of existing aquatic communities. The study request suggests multiple sampling event rather than a multiple year study. A quick look, what's there, what if anything, has changed? Very reasonable. FERC staff, not the licensee, should be allowed to decide if this proposed study meets study goal criteria.

The licensee has again misrepresented the facts. For 50 plus years the Ripogenus Impoundment's smelt population was "stable" and the salmon population thrived. This is no longer the case. While the licensee correctly notes the variability of smelt populations, they offer no proof e,g,, peer viewed publications, of a 15 year decline in other waters where smelt have no direct competition, e.g., alewives. Year class fluctuation is typically between alternate years.

The licensee cites the MeDIFW position that there is an overpopulation of landlock salmon in the Ripogenus Impoundment. That salmon are over-populating the impoundment is an

assumption/hypotheses. The more likely fact based on MeDIFW's 2021 West Branch drift net collections is that the plankton/smelt relationship has changed. For 50-60 years the Ripogenus salmon population was stable. Without Ripogenus smelt data, how can MeDIFW possibly state that there are too many salmon rather than too few smelt? FERC staff should consider the peer reviewed literature (see January 27, 2022 filing) and the importance of Ripogenus smelt populations(s) and act accordingly.

The licensee also quotes a MeDIFW report that many lakes are overpopulated with salmon. This is true in some cases but the licensee's rebuttal, as in many cases, misses the point. Are any of the MeDIFW referenced lakes, historically famous for their salmon fisheries, witnessed a collapse of the fishery that lasted for perhaps 15 years? For lakes that are overpopulated by salmon, what is the condition of the smelt population? In fact, how many of the lakes in question have smelt populations.? How many of the referenced lakes are managed by stockings? As has been the cases in many of the licensee's objections, they do not back up their criticism with data or peer reviewed studies.

In setting up its legal defense, for circa 2026, the Licensee argues that any phyto or zooplankton study would be inconclusive. These data must be of important as the licensee included 1980-1984 zooplankton data in its 2021 filings. How can the licensee state the data are inconclusive before the study is completed? Rather than speculate about the results, why not find individuals more expert than me along with FERC staff to judge the value/relevance of these yet to be collected data. Clearly, evaluating the plankton/smelt community will provide data on which FERC/MeDEP can require PM&E measures.

7.1.4 Riverine Aquatic Habitat Assessment

In its October 8, 2021 filing MeDIFW (Study Request 10) commented on macro invertrabrate sampling in the Ripogenus Impoundment and in the downstream West Branch. *"We recommend the sampling take place in the same locations in the Ripogenus impoundment and the section of river between McKay Station and Ambajejus Lake".* However, the licensee's proposal is diabolically different from the MeDIFW study request. The Licensee is proposing reduced sampling and at one site, that location is not representative of the 20 mile downstream river reach.

The licensee is proposing to set up macro invertrabrate sampling immediately below McKay Station, the Millinocket and Dolby Dam Faculties. Such sites are not representative of downstream reaches and are thus not acceptable. During construction, In order to reduce tailwater elevation immediately below turbines at each station, ledge and rocks were moved to produce high exit velocities. These necessary engineering measures produced 300- 500 yards of what in effect are open culverts. The resulting habitat is not representative of downstream habitat and in fact, velocities and substrates below McKay are so extreme salmon are unable to overwinter in this same area that supports an extremely high quality "summer" salmon fishery. The licensee mentions safety measures, thus is obviously aware of this extreme and unnatural

environment. When the Maine legislature approved of water quality designation standards such as “naturally occurring” and agencies developed a 75% zone of passage criterion it is unlikely draft tube discharge areas were considered as sampling sites. “Naturally occurring” automatically dismisses such areas. It is clear that legislature and agency’s standards were NOT intended to be applied to what in reality are human construction excavations that produced high velocity open culverts

Macro invertrabrate sampling should not simply be “pro forma”, rather it should produce actionable information. There are indications the macro invertrabrate populations, namely Ephemeroptera, Plecoptera, and Trichoptera (EPT) have decreased in recent years in the waters downstream of McKay Station. MeDIFW commented on the reduced “hatches” of adult mayflies and stoneflies and caddis moths in its October 8, 2021 filing. Life stages of all EPT are important to salmon of all year classes and critical to adult salmon during the summer maintence period. A study site located in the upper 1000 ft of the West Branch is not indicative of conditions in the remaining 20 plus miles of river. A number of historic, 1980s, study sites are shown in the Ripogenus Project Application, any of those sites are more representative of substrates, flow and depth than the high velocity steep sided area immediately below McKay Station. Penobscot Mills study sites are included in the 1991 FERC Application. Any macro invertrabrate site(s) should be representative of the river populations and comparable to historic population(s) abundance(s) and distribution.

It appears that the licensee is proposing one macro invertrabrate station “with three replicate samplers downstream of McKay Station”. If this is the case, I strongly object. FERC should listen to MeDIFW and execute their very reasonable request.

**Appendix B West Branch Channel Study Plans**

**2.0 Goals and Objectives**

*The goal of this study is to assess the relationship between flow and aquatic habitat in the West Branch below Stone Dam using a standard and accepted methodology, such as the Instream Flow Incremental Methodology (IFIM). GLHA understands that MDIFW’s primary interest is the effect of flow on habitat for coldwater fisheries, in particular brook trout and landlocked salmon, and the potential for a seasonal put-and-take fishery*.

The West Branch Channel (Backchannel) has been dewatered for approximately 120 years. For the last 30 plus years, the cause of dewatering was economic concerns, e.g., the loss of Millinocket Mill jobs (see 1996 EIS). It is time for FERC to restore the balance between environmental and recreational goals, the local “recreation based” economy and the need for power generation.

While landlocked salmon are referenced RSP West Branch channel study plans, there is no mention of life stage. The importance of all salmon life stages needs to be included and

evaluated in any study. Study sites need to representative of substrates best suited for juvenile salmon productions rather than a short-term put-and-take hatchery brook trout population.

The licensee currently supports a “put and take” brook trout fishery in Millinocket Stream. This stream parallels the Grindstone Road and provides easy access to the stocking truck as well as anglers. The Millinocket Stream put and take fishery seems to be producing the desired results.

In the eagerness to propose a West Branch “put and take” trout fishery, MeDIFW and the licensee have failed to produce a few details; angler demand, access and logistics. Presently vehicle access to the old river channel is blocked by fencing and the only possible access is via boat. More importantly, access along the channel is via an old road on the Western side of the river, the old CCC trail, this is only usable by four wheel drive vehicle, and reachable only by crossing the West Branch and then only during “no flow events”. Thus, to make a “put and take” fishery work, a bridge across the channel (that would survive PMF flows) or a road down the eastern side of the river will be required. A “field of dreams” argument is not acceptable. The Licensee and MeDIFW need to explain how dependable streamside access will be provided to the hatchery truck and anglers and the capital and maintenance costs of these necessary actions.

Circa 1994, I received a call from Mill security notifying me of salmon trapped below Stone Dam following a late Spring/early summer spill event. We loaded the electrofishing gear and drove to Stone Dam where we removed 40-50 adult salmon (see Great Northern Papers files). This event, along historic angler reports, is evidence of salmon responding to high flows and the natural tendency to “drop” downstream. Thus, salmon will always enter the West Branch Channel during high flow events, the remaining question is the provision of an appropriate flow.

Additionally, salmon anglers have demonstrated a willingness for long boat trips to fish for legal sized landlock salmon in riverine environments. As shown in the Ripogenus and Penobscot Mills Projects Appendices, anglers cross Pemadumcook Lake to fish Nahmakanta Stream, Ambajejus Lake to fish the West Branch, and Chesuncook Lake to fish the Upper West Branch, when quality salmon fishing opportunities exist. Thus, the development of the West Branch channel as salmon habitat will produce salmon spawning and nursey habitat as well as an opportunity to catch legal size salmon (1996 EIS). Thus, developing the West Branch as salmon habitat meets multiple MeDIFW goals. Watering the West Branch channel represents passive management as no roads or bridges or hatchery trucks are required. In addition, West Channel flows will provide excellent canoeing and kayaking opportunities. The trip from North Twin (Rt 11) downstream to the Dead Man’s Curve is approximately eight miles.

**3.0 Resource Management Goals**

*While MDIFW generally manages Penobscot Mills Project waters for coldwater fish, the agency does not have a fishery management plan that includes explicit goals for management of the West Branch below Stone Dam. However, in their October 8, 2021 letter, MDIFW outlined their*

*current fishery management interests in the West Branch below Stone Dam: Due to changing MDIFW fisheries goals and growing angler pressures in the region, MDIFW is trying to establish a seasonal put-and-take fishery in this resource [West Branch below Stone Dam] to provide more angler opportunities. Given changing MDIFW management objectives for this resource since the original license was issued, MDIFW requests that minimum flows be re-evaluated at the [West Branch below Stone Dam] (MDIFW 2021a).*

IN my January 7, 2021 filing I requested MeDIFW evidence of ***"growing angler pressures in the region"*** to date***,*** none has been provided. Thus, the MeDIFW statement stands as an opinion, based on little or no information. Having reviewed countless comments concerning my fact based filings, called opinions by the licensee, it is difficult to understand why some opinions are valued to the extent of providing study justification, while others are not.

While there may be angler demands to catch ten inch hatchery trout, there is a documented needed for riverine salmon fishing opportunities. The licensee and MeDIFW appear to reject practical fisheries goals. MeDIFW is setting up arbitrary, unsupported fisheries management objectives. One of the suggested "study species" is brook trout, a species requiring little or no flow, this fits well with licensee's goals of limiting flow in the West Branch Channel. The MeDIFW proposal "flies-in-the face" of MeDIFW stated policy. From the 2021 draft MeDIFW salmon management plan and the PAD (5.4.1.1) the current salmon management includes;

- statewide management goals for landlocked salmon are to maintain the current distribution of principal fisheries for landlocked salmon, provide for a diversity of fishing opportunities, maintain and where possible expand the contribution of wild salmon to the population

The 2022 plan adds;

Maintain or enhance existing (salmon) populations *(High Priority)*

*"Identify potential strategies—including regulation, partnerships, habitat modification, ….."*

*Maintain healthy and sustainable landlocked Atlantic salmon fisheries*

*"Advocating for in-watershed land and water management practices that maintain or enhance spawning and rearing habitats for wild populations, where populations are not over abundant,"*

<u>The West Branch channel or Back Channel provides an excellent opportunity to create a self-sustaining salmon fishery and accompanying juvenile production</u>.

The 1996 EIS examined the West Branch (AKA Back channel) at a variety of flows before bowing to the economic needs of Great Northern Paper. That concern no longer exits. FERC Staff analyzed Back Channel adult salmon habitat at a 350 cfs flow. They wrote that the "*approximately 245, 3-year-old fish would be produced over the 4.5 mile reach. The estimated 245 adult salmon in the back channel represents only 61 fish per mile per mile, well below the*

*state standard of 83 fish per mile per year required for moderate quality fisheries (DIFW 1991)"*. The actually length of potential riverine salmon habitat between Stone Dam and Shad Pond is approximately three miles. Additionally, Shad Pond, below Grand Falls, provides downstream overwintering habitat. The number of 3-year-old salmon (used in the FERC analysis) is approximately 383 adult salmon as that age class is carried though its life expectancy (assuming 40% survival to age V). Thus, if the corrected 383 number of salmon is divided by the actually length of salmon habitat (3 miles), then the product far exceeds MeDIFW goals. This is even better given today's anglers catch and release trend, where fish caught and released, and caught again, the effective catch would be around 700 fish. Pretty good fishing. Ultimately, FERC staff demised and Back Channel flows citing the loss of 240 Mill jobs. There is no longer a Mill and no longer any need to protect jobs and West Branch Channel is needed to mitigate lost North Twin tailwater juvenile salmon production and to supplement the downstream Millinocket facility salmon population as well as providing fishing opportunity.

The licensee and MeDIFW appear to reject practical fisheries goals. MeDIFW is setting up arbitrary, unsupported fisheries management objectives. One of the suggested "study species" is brook trout, a species requiring little or no flow and NO stream velocity, this fits well with licensee's goals of limiting flow in the West Branch Channel. The MeDIFW proposal "flies-in-the face" of stated policy. From the 2021 draft MeDIFW salmon management plan and the PAD (5.4.1.1) the current salmon management includes;

- statewide management goals for landlocked salmon are to maintain the current distribution of principal fisheries for landlocked salmon, provide for a diversity of fishing opportunities, maintain and where possible expand the contribution of wild salmon to the population

The 2022 plan adds;

Maintain or enhance existing (salmon) populations *(High Priority)*

*"Identify potential strategies—including regulation, partnerships, habitat modification, ….."*

*Maintain healthy and sustainable landlocked Atlantic salmon fisheries*

*"Advocating for in-watershed land and water management practices that maintain or enhance spawning and rearing habitats for wild populations, where populations are not overabundant*".

The Great Northern Paper mills are no longer operating and the local economy has become dependent on recreational activity. A West Branch channel salmon fishery would provide fishing opportunity, salmon nursey habitat as well boating activities for canonist and kayakers. FERC staff should consider practical fishery management options that meet multiple goals that balance environmental and recreational needs with power generation.

**Studies Suggested in the Comment Period but not Addressed in the Revised Study Plan**

Minimum operating flows below McKay Station

During the recently closed commenting period, I submitted a February a 22, 2022 filing that dealt with West Branch low or minimum flow periods below McKay Station. MeDIFW referenced flow issues in its October 8, 2021 filing;

*"An evaluation of minimum flow provisions is necessary to determine how best to meet the various resource needs including those of the Licensee, which may not be consistent among the various agencies and other interested parties. These data will inform conclusions regarding impacts to aquatic habitat to determine whether modifications to Project operations are needed. Data derived from this study will facilitate evaluation of the existing minimum flows, inform MDIFW's decision process, and contribute to the development of an administrative record in support of protection and enhancement opportunities for freshwater fisheries and the aquatic community at large."*

No attempt was made in the RSP to address the biological impacts resulting from daily flow reductions to outflows of 1000 cfs. The licensee has changed operation to a peaking regime where typical 2021 summer flows were increase to 3000 cfs in the morning and reduced to 1000 cfs in the evenings. Such operations result in devastating impact to fish and aquatic communities. This flow regime and the current operating minimum needs to be addressed and if needed corrected.

The present licensed McKay Station minimum flow was set in 1996 when Great Northern Paper Mills were still operating. Mill production was running 24X7X365 and daily major flow reductions were never a major consideration. Thus, a minimum flow standard was developed based on the assumption that any minimum flow would only be needed in maintenance emergencies or Mill production crisis. Initially the USFWS generic flow prescription of one cfs/square mile (1455 cfs) was set as minimum a flow, this was later reduced to 1300 cfs and finally to 1000 cfs; a flow based on McKay Station optimal turbine efficiency. Historic flow records available during 1992 licensing supported this stakeholder decision. That was then, this is now.

The 2021 August-September overnight flow reduction impacted a litany of guilds;

* The most obvious impact was the daily evening dewatering of the Holbrook bypass channel, see Article 406 of the 1996 401 WQC. This spawning and nursey area habitat modification was requested by MeDIFW to enhance young-of-the-year (YOY) juvenile salmon production, the salmon life stage considered to be limiting the abundance of salmon in the West Branch. Nightly dewatering of this critical enhancement measure eliminated any significant contribution YOY and parr to the West Branch adult salmon population. Nightly dewatering also threatened the limited downstream salmonid nursey areas.

* Less visible are the impacts on all life stages of salmonids, the sudden change in flow can result in stranding and in all cases require to move to adjust to changing depths, velocity.

Additional, energy is required to constantly find new micro habitats, this movement increases predation and reduces “feeding” time.

* Less Visible are the impacts to macro invertrabrate communities. Aquatic insects are vulnerable to dewatering and desiccation, additionally trichopteran species such as the Hydrophyscid family loss the ability to construct nets and gather food during up and down flow events.

* More visible is the impact on anglers who are forced to move (as do the fish) and change their fishing position in response to flow changes. No only do anglers have to move but they also have to guess where the fish have moved to.

There is a clear need to develop an operational minimum flow that is based on biological needs of fish and aquatic communities. Genetic flow prescriptions, Tenant, ABF, Montana, 7Q10, etc. that look only at past hydrology i.e., flow records, are inappropriate for low flow operations that occur daily. Daily/weekly/ monthly flow requirements for litany of fish and aquatic species change throughout the five to six month growing season. There is a clear need for instream flow studies that addresses the dynamically changing flow and habitat needs of fish and aquatic communities. There is not “one flow prescription fit all” scenario.

**Upper Gorge flow Studies**

The impact of temperature differnces between deep gate and log sluice flows into the Upper Gorge during the July 1 to September 30 enhancement period need to determined and cool attraction flows into the Upper Gorge need to be provided.

In his October 8, 2021, filing Paul Johnson, the former senior Biologist at the Greenville Regional Office, and principal MeDIFW representative during the Ripogenus Licensing provided the following comments and request, and MeDIFW echoed these concerns its October 8, 2021 filing;

*“Flows in the Upper Gorge between Ripogenus Dam and McKay Station have not met the objectives for this section of river for the past 25 years! Article 401 of the current license requires a July 1 - September 30 discharge of 100 cfs into the Upper Gorge to provide a cool flow that would attract adult salmon and increase fishing opportunity in the gorge during this period. The recommendation for this flow and its timing was based on observations in years prior to the 1990’s, when minimum flows discharged to the West Branch with McKay Station shut down were provided through a deep gate in Ripogenus Dam – hence the cool water. Unfortunately, for the past 25 years the 3-month discharge has been through a small sluice gate that provides warm, surface water to the Upper Gorge, defeating the purpose of Article 401 – 25 years of lost mitigation/enhancement. I recommend 1) studies to determine an appropriate annual minimum flow for the Upper Gorge, and 2) that a new license contain a condition requiring that the 1 July 1 – September 30 flow in the Upper Gorge be provided through a deep gate in*

*Ripogenus Dam, or through an alternative to a deep gate that will provide at least 100 cfs from deep water, not surface water, in Ripogenus Lake."*

In its October 8, 2021 filing MeDIFW stated; *"It was the intent of MDIFW that the flows in the Upper Gorge would originate from a deep gate and therefore provide a cool water attraction flow as adult salmon reached the upper river in July. However, the water is released from a sluice (surface) gate which is warm water. This water is warmer than the water passing through McKay Station into the river and is therefore ineffective as an attraction flow. We request Brookfield develop a plan to provide a 100 cfs flow from July 1 to September 30 into the Upper Gorge from below 45 feet (summer thermocline location) in the impoundment to fulfill the original intent of this mitigation and provide additional fishing opportunities."*

The Licensee has not followed up on this simple MeDIFW request. The placement of a recording thermometer extending a meter or two into the impoundment can easily correct part of this oversight and provide a contrast between water surface, and mixture of "epilinnetic/thermocline" flows, or sub surface waters discharged from the McKay Station turbines. Temperature data will provide answers as to the most appropriate methods (deep gate, siphon, etc.) to cool Upper Gorge summer flow.

This filing represents a multitude of concerns and study suggestions. I hope that FERC staff will give the above pleadings careful consideration and require the studies necessary to produce current information on the fisheries and aquatic communities so critical in all project water.

Thank you

Project Nos. 2572-133 & 2458-247 –
Maine
Ripogenus Hydroelectric Project
Penobscot Mills Hydroelectric Project
Great Lakes Hydro America, LLC

**VIA FERC Service**

Julie Crocker
Protected Resources Division
National Marine Fisheries Service
55 Great Republic Drive
Gloucester, MA 01930

**Reference: Response for Extension of Time to File Comments on Revised Study Plan**

Dr. Ms. Crocker:

On March 23, 2022, Great Lakes Hydro America, LLC (GLHA) filed its Revised Study Plan (RSP) for the Ripogenus (P-2572) and Penobscot Mills (P-2458) Projects. In response, the National Marine Fisheries Service (NMFS) requests that the Commission grant a 60-day extension of time to file comments on the RSP (to June 6, 2022) to allow for a review of the 10 years of operation data filed with the RSP. NMFS indicates that this information was filed late, and the agencies and stakeholders now have only 15 days to review and comment on the data. NMFS states that the additional 60 days is needed to afford the agencies and stakeholders time to review the operations data and factor it into their responses to GLHA's RSP.

On October 8, 2021, Commission staff requested that GLHA provide 10 years of operations data to, among other things, document the Projects' operations, as described in the Preliminary Application Document. This information was to be provided as part of the GLHA's Proposed Study Plan (PSP). However, the requested data was not included in the PSP, but instead was, as noted above, filed as part of the RSP. Because documenting how the Projects operate could guide study design, additional time to review the requested data is reasonable. However, an additional 21 days, rather than 60 days, should be sufficient to review the data and incorporate it into responses on GLHA's

RSP, while avoiding delays in any required studies this field season.[1] Therefore, comments on the RSP are now due by April 28, 2022, and the due date for the Study Plan Determination (SPD) is May 13, 2022.

If you have any questions regarding these matters, please contact Allan Creamer at (202) 502-8365, or allan.creamer@ferc.gov.

Sincerely,

Vince Yearick
Director
Division of Hydropower Licensing

**RE: Comment on RSP, Ripogenus Project (FERC No. 2572) and Penobscot Mills Project (FERC No. 2458)**

Dear Secretary Bose,

The Bureau of Parks and Lands (BPL) submits the following comments in response to the filing of the Revised Study Plan (RSP) for the Ripogenus Hydroelectric Project and Penobscot Mills Hydroelectric Project (FERC Project Nos. P-2572, P-2458) by Great Lakes Hydro America, LLC ("GLHA" or "licensee"), to inform FERC's development of the Study Plan Determination.

BPL participated in the initial scoping meeting, submitted PAD comments as well as study requests for these projects; and commented on the licensee's Proposed Study Plan. We file these comments to address remaining deficiencies in GLHA's RSP, to voice support for related comments by other stakeholders in the FERC relicensing, and to help ensure robust data is obtained to adequately understand the recreational impacts of project operations within and adjacent to the project boundary.

Revised Study Plan, Appendix F – Recreation Study Plan
*7.3 Recreation User Survey*
The licensee proposes to administer the recreation user survey via kiosks at FERC-approved Project recreation sites (with a QR code to permit visitors to complete the survey electronically if they prefer). BPL is concerned that this method will under-represent or perhaps exclude the users of the 10 Chesuncook Lake remote campsites. The understanding of BPL staff at the Penobscot River Corridor (PRC), who manage the sites, is that most campers using those campsites launch and/or take-out from the lake at one of the following two sites, neither of which is included among the FERC-approved recreation sites as listed in the Study Plan:

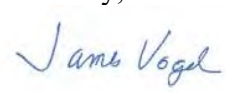
1) Umbazooksus West boat launch -- only the campsite at this location is included in FERC-approved recreation sites; the Bureau questioned this in our prior comments because the 2008 Recreation Facility Report for the projects submitted to FERC (GLHA 2009, as referenced in the PAD) lists Umbazooksus Stream as a public boat launch. Per the Study Plan, campsites will not be included in the recreation user survey.

2) Graveyard Point boat launch -- informal gravel launch at Chesuncook Village, on BPL property and managed by the PRC. Access road improvements in recent years have made this a more attractive option for Chesuncook campsite users and other boaters.

We are also concerned that campowners on Chesuncook Lake will not be included in the survey without traveling to one of the FERC-approved recreation sites. To address these concerns, we request that the recreation user survey methodology be expanded to include an on-line survey (and the means to alert the visiting public to it) and stakeholder focus groups, to include campowners. We support the similar request by AW and AMC in their comments on the RSP, and also their request that the scope of the study include all informal recreation sites as well as those recreation sites located near and adjacent to the projects. Including informal sites would encompass the above two sites on Chesuncook Lake.

The Bureau offers GLHA assistance in informing the visiting public of the opportunity to participate in an on-line recreation survey, and in distributing the survey electronically.

Revised Study Plan, Appendix H – Aesthetics Study Plan
*6.0 Methodology*
GLHA has adopted the Aesthetic Resources Study requested by several stakeholders, and we believe the proposed study will provide useful and valuable information regarding the aesthetic impacts of the project. However, as expressed in our previous comments, we are interested in documenting the aesthetic impact of impoundment drawdown at the Ripogenus impoundment (Chesuncook Lake) and are concerned that the proposed study will not fully capture this. We believe that the substantial amount of drawdown at Chesuncook Lake may have an important effect on the enjoyment of boaters on the lake and users of the remote boat-in campsites. The 2010-21 operations data provided in Appendix S of the RSP indicates a drawdown of 20 feet or more below full pool occurs most years.



Therefore, BPL requests that the Aesthetics Study specifically address views of the lake and surroundings as experienced by boaters from the lake surface as well as from FERC-approved recreation sites (as GLHA intends to do as described in the Aesthetics Study methodology, page H-6). Specifically, several representative locations on the lake surface should be added to the list of Key Observation Points.

*Also: Recreation Study, 7.3 Recreation User Survey & Attachment 1*
To address the same concern, the Bureau also recommends that the recreation survey instrument, provided as an attachment to the Recreation Study Plan, be modified to directly address the issue of the effect of drawdown on aesthetics and visitor enjoyment. The survey instrument includes a general question (#15. "What did you "like least" about your recreational experience today?") that may solicit responses on adverse conditions such as severe drawdown, but that does not

probe the issue directly, as we believe is needed. This comment pertains only to the Ripogenus Project.

Thank you for the opportunity to submit these comments. Please feel free to contact me at (207) 287-2163 or via email at Jim.Vogel@maine.gov if you have any questions regarding these comments.

Sincerely,

James Vogel, FERC Coordinator

RE: Comments on the Revised Study Plan for the Ripogenus (FERC No. 2572) and Penobscot Mills (FERC No. 2458) Hydroelectric Projects

Dear Secretary Bose:

The Maine Department of Environmental Protection (Department) received and reviewed the Revised Study Plan (RSP) submitted on March 23, 2022, by Great Lakes Hydro America, LLC (Great Lakes, or Applicant), for the Ripogenus and Penobscot Mills Hydroelectric Projects (Projects), located on the West Branch of the Penobscot River.

The Projects are subject to water quality certification provisions under Section 401 of the Federal Water Pollution Control Act (a.k.a. Clean Water Act). By Executive Order of the Governor of the State of Maine, the Department is the certifying agency for water quality certifications.

Fish Assemblage Study

In its comments on the Proposed Study Plan, the Department requested a Fish Assemblage Study that would be used to demonstrate, in part, whether the Projects meet applicable water quality standards. Specifically, the impounded waters must support all species of fish indigenous to those waters. The results of the Fish Assemblage Study would also be used as evidence that could demonstrate attainment of the designated use of habitat for fish and other aquatic organisms.

In the RSP, Great Lakes does not adopt the Department's requested Fish Assemblage Study, and instead proposes to conduct a Fishery Assessment as part of the Impoundment Aquatic Habitat Assessment component of the Water Quality Study. The Fishery Assessment would not involve any scientific sampling of fish populations. Instead, it would rely on existing information and interviews with various parties.

Although Great Lakes did not directly address the Department's request in its rationale for not adopting the Fish Assemblage Study, it did address a similar study request from a stakeholder group. Great Lakes appears to base its decision not to adopt the Fish Assemblage

Study on its assertions that existing information is sufficient [section 5.9(b)(4)], that study results are not likely to inform potential license conditions [section 5.9(b)(5)], and that the study methods proposed by the stakeholder group (gill netting) are not consistent with generally accepted practice in the scientific community [section 5.9(b)(6)].

The Department disagrees with Great Lakes' assertions. First, existing information would not be sufficient to demonstrate that the Projects are currently meeting water quality standards. Historical and anecdotal data could be useful for fisheries managers, but it is unlikely to provide sufficient, defensible data for the Department to determine that the Projects' currently support all indigenous species of fish. Comprehensive, scientific sampling of fish populations would provide sufficient data to draw conclusions about the Projects' effects on water quality [section 5.9(b)(4)]. Second, the results of a Fish Assemblage Study would directly inform potential conditions that the Department could require in any Water Quality Certification it would issue for the project. Study results would be used to demonstrate attainment of water quality standards related to fish populations in addition to providing evidence that the Projects meet water quality standards related to aquatic habitat more generally. If evidence of nonattainment is found, the Department will use the study results to inform the development of measures to mitigate for the Projects' effects on water quality. This is critically important to the relicensing proceeding, because FERC must include Water Quality Certification conditions in any new licenses for the Projects [section 5.9(b)(5)]. Third, the Department did not provide specific methods in its request since this type of study is commonly conducted in many FERC relicensing proceedings. Great Lakes' response focused on their concerns with the stakeholder group's proposed methods for collecting fish samples (gill netting). Great Lakes did not discuss any other generally accepted, and more commonly used, practices that the scientific community typically uses in fish assemblage studies, such as electrofishing. Due to this omission, Great Lakes' response did not fully address the study criteria, nor does it provide a basis for Great Lakes to not adopt the Department's requested study [section 5.9(b)(6)]. For these reasons, the Department requests that FERC determine that Great Lakes must complete a Fish Assemblage Study.

Thank you for the opportunity to review and comment on RSP for the Ripogenus and the Penobscot Mills Hydroelectric Projects.

Sincerely,

Kyle Olcott

**Re: MDIFW Comments on the Revised Study Plan for the Ripogenus Hydroelectric Project (FERC No. 2572) and Penobscot Mills Hydroelectric Project (FERC No. 2458)**

Dear Secretary Bose:

On March 23, 2022, Great Lakes Hydro America, LLC (GLHA), a subsidiary of Brookfield Renewable (Brookfield, Licensee), submitted their Revised Study Plan (RSP) for both the Ripogenus Hydroelectric Project (FERC No. 2572) and Penobscot Mills Hydroelectric Project (FERC No. 2458). The Projects are located on the West Branch of the Penobscot River and Millinocket Stream, and span both Piscataquis and Penobscot Counties, Maine. The Maine Department of Inland Fisheries and Wildlife (MDIFW) provides the following comments.

## Fisheries

### *Ripogenus Project*

MDIFW originally requested a macroinvertebrate study of the Ripogenus impoundment, as well as in the river below McKay Station. Our request is satisfied by the proposed Water Quality Study Plan as outlined in Appendix A.

We also expressed concerns over the following:

1. The lack of cold water in the attraction flow in the Upper Gorge. These attraction flows were required in the previous license and intended to provide cold water attraction for salmonids. This concern is addressed in the Water Quality Study outlined in Appendix A.
2. Reduced boat access due to low summer lake elevations. This concern is addressed in the proposed Recreation Study Plan.
3. The apparent change to peaking flows through McKay Station causing disruptions in the fishing and macroinvertebrate populations in the river. The macroinvertebrate concern (MDIFW's Study Request 10: Macroinvertebrates Study Request—Ripogenus Project) will be addressed in the proposed Water Quality Study. We request that an analysis of hourly flows be included in the proposed Historical

PHONE: (207) 287-5254 FISH AND WILDLIFE ON THE WEB: www.maine.gov/ifw EMAIL ADDRESS: IFWEnvironmentalreview@maine.gov

Operations Data Assessment so we may determine the degree and frequency of peaking flows in the river. We believe there is adequate information in the literature to assess impacts.

4. The loss of fishing sites at McKay Station due to fencing installed by GLHA. This concern was not addressed in the Revised Study Plan and should be added to the Recreation Study Plan. GLHA should enumerate the number of fishing sites used by anglers during spot checks.

GLHA states that they will work with the Maine Department of Agriculture, Conservation and Forestry and MDIFW to obtain both commercial and private whitewater boating registration data collected at McKay Station as part of the proposed Recreation Study Plan. We request that GLHA include an analysis of daily whitewater registrations by weekday for each month from May through September. Specifically, we would like to be able to determine the total number and percent of use on each weekday (For example, X number of people (representing X percent of the total use) is occurring on Mondays in May, etc.)

***Penobscot Mills Project***

As initially described in our initial Study Request 8: Landlocked Salmon Habitat Use/Spawning Study, and as reiterated in our February 22, 2022 comments on the Proposed Study Plan, MDIFW continues to recommend a landlocked salmon radiotelemetry tracking study be conducted in the North Twin impoundment. The goals and objectives of this study include:

- Track seasonal movements and behaviors of landlocked salmon (within and between the five connected lakes) via radiotelemetry.
- Determine the effects of annual Project drawdowns on the movement and behaviors of landlocked salmon within the North Twin impoundment.
- Identify landlocked salmon spawning areas within the North Twin impoundment.

It remains unknown what affect Project operations have on landlocked salmon spawning movement and behavior on selection of spawning tributaries in the North Twin impoundment. It is generally accepted that salmon utilize large inlets and outlets for spawning and rearing[1]. However, it has also been documented that salmon will spawn in lakes, especially near mouths of large inlets, in moving water near outlets, and among wind-swept shoals[2]. The Licensee's proposal to conduct a tributary access study without radio tagging salmon would not identify spawning activity within the lacustrine habitat of the North Twin impoundment. Additionally, any salmon movement into the outlet during the fall spawning period would not be documented. Outlet flows of the North Twin impoundment are controlled by the Project's North Twin Dam and could have an effect on spawning timing and success. Radio-tagged salmon would identify

potential salmon movement into the outlet and the efficacy of the North Twin Dam fishway to pass salmon back upstream into the impoundment after spawning.

## Wildlife

### *Common Loon Productivity Assessment (Penobscot Mills)*

The Licensee believes that the Historical Operations Data Assessment Study will provide information on how the Penobscot Mills Project has been operated over the term of the existing license, including impoundment elevations during the loon nesting season. Additionally, GLHA proposes to utilize the Operations Model Study to evaluate alternative operating scenarios (including the resulting impoundment elevations) to be considered for the new licenses, which will be compared to historical operations data to understand if changes in operation may be affecting nesting loons on the Millinocket Lake and North Twin impoundments.

MDIFW supports this approach; however, we reserve the right to reiterate our request for an assessment of common loon productivity at these impoundments.

### *Wood Turtle*

MDIFW appreciates GLHA's cooperation in assessing potential impacts to wood turtles as a result of Project operations and supports the proposed phased study approach. Given the vastness and remote nature of the Project area, prior to any Phase 1 (and Phase 2, if necessary) field work, we recommend that GLHA work with MDIFW to ensure that final field study methodology and objectives are mutually agreed-upon.

### *Furbearer Study*

Based on conversations with MDIFW, GLHA has adopted a Furbearer Survey Study at the Ripogenus Project; however, this study has been modified from our original October 8, 2021 Study Request.

We want to emphasize that detection of both beavers and muskrats can be difficult: this is especially true for muskrats, which can live in the most discrete places making detection extremely difficult for any furbearers residing in bank dens and backwaters. Based on the experiences of MDIFW regional wildlife biologists, oftentimes muskrats live in bank dens and often require a fairly high level of effort to detect, making detection by observers in a boat unlikely. We stress that the level of effort necessary for this study will require observers traversing, by foot, areas of backwaters, shallow coves, and other sites where a boat may not be able to travel.

### *Littoral Zone/Macroinvertebrates*

In our October 8, 2021 PAD Comments and Study Requests, MDIFW recommended Study Request 2: Exposed Aquatic Habitat Assessment, which has been adopted by GLHA as part of their proposed Riparian and Littoral Habitat Assessment Study Plan. The goal of Exposed

Aquatic Habitat Assessment is to quantify the total area of exposed aquatic substrate of all waterbodies comprising both the Ripogenus Project and Penobscot Mills Project. The assessment should consider exposed substrate, relative to the full pond elevation of each waterbody, during three scenarios:

- 10-year average annual drawdown for each waterbody
- low-water years for each waterbody, using 2021 water levels
- under maximum allowable drawdown for each waterbody

Additionally, we requested a quantitative assessment of exposed aquatic substrates in the downstream riverine ecosystems for each project, including analyses of both the mainstem West Branch downstream of Quakish Lake ("Back Channel") and Millinocket Stream.

In Table 1-1 of the PAD, GLHA designated this request as "Adopted with Modification" as part of the Water Quality Study, while in Table 1-2 of the RSP GLHA designated our study request as "Adopted with Modification" as part of their proposed Riparian and Littoral Habitat Assessment Study. We appreciate this clarification and conceptually agree that most aspects of our requested Exposed Aquatic Habitat Assessment have been captured in the proposed Riparian and Littoral Habitat Assessment Study. However, it is unclear why GLHA is proposing to not adopt the portion of the study request related to evaluation of exposed substrates and habitat in the riverine reaches of the Project areas into this proposed study plan. Whereas this information is already being collected as part of several other surveys (i.e. the Historical Operations Data Assessment Study, Water Quality Study, Instream Flow and Habitat Assessment of the West Branch Downstream of Stone Dam Study, and Wood Turtle Habitat and Presence Study), we believe it should be a relatively simple exercise to have this information incorporated into the Riparian and Littoral Habitat Assessment Study. Having all the assessments in a single document will greatly aid in review of the results.

Finally, it should be noted that the many of documented, modeled, and predicted SGCN aquatic or aquatic-associated invertebrate species in the Project area, as listed in the PAD and below, require specialized experience, specific survey protocols, and proper seasonality to detect. We are <u>not</u> recommending surveys for these species; we mention this because the RSP states that observations of wildlife will be included, and we want to impress that most of these species below will not be documented through general wildlife surveys.

Subject: **Comments of Maine Council of Trout Unlimited on the Revised Study Plan for the Ripogenus Project (P-2572) and the Penobscot Mills Project (P-2458)**

Dear Secretary Bose:

On behalf of its six chapters and over 2,000 members, Maine Council of Trout Unlimited (TU) submits these comments on the Revised Study Plan (RSP) for the Ripogenus Project (P-2572) and the Penobscot Mills Project (P-2458) filed for Great Lakes Hydro America, LLC by Brookfield Renewable ("Brookfield" or "Applicant") dated March 23, 2022. Given the content of the RSP, the comments on the Proposed Study Plan for the project that we submitted with the Appalachian Mountain Club ("AMC"), American Whitewater ("AW"), Caribou, Chesuncook Lake Camp Owners Association, Chesuncook Dam Camp Owners Association, the Allagash Gateway Campground, and Andre Emerson Cushing Corporation[1] ("NGOs") remain germane to this filing as well.

**General Comments**

The Applicant began the PAD stating that the full suite of studies is not needed.[2] It went on to review the 35 study requests submitted by organizations and only proposed conducting 3 without modification, accepted 13 more with modification or included them with other studies, and rejected 19 outright.[3] TU acknowledges that studies should not be repeated that continue to meet project information requirements, but that should be assumed to be generally not the case with studies that are 30 to 40 years old. While TU appreciates that the Applicant has included additional studies in the RSP increasing the number of proposed studies to 40[4] and increased the number of studies it proposes to perform to 16, the proposed studies still do not adequately address significant requests for information that remain unfulfilled or that weaken or dilute the studies so that they will not inform the

[1] TU filing of February 10, 2022, Accession number 20220210-5189.
[2] Brookfield Notices of Intent and Pre-application Documents for the Ripogenus Project (P-2572) and the Penobscot Mills Project (P-2458) dated June 11, 2021, page 1-11. "*GLHA maintains that a full suite of new studies is not needed, that the vast body of information on which today's certifications and licenses are soundly based and should be relied upon for these relicensings. In addition, consistent with the Commission's criteria for study requests, the scope and extent of any new study be focused on addressing specific data gaps necessary to inform the development of license requirements.*"
[3] PSP, page 1-19, Table 1-1 title: "*Stakeholder Study Requests for the Ripogenus and Penobscot Mills Project and GLHA's Determination.*"
[4] RSP, Stakeholders Study Requests, Table 1-2, pages 1-26 to 1-28. The actual number of study requests is higher – TU's Fish Assemblage Study Requests were for 10 separate studies to examine all the reaches described in the PAD.

project. This renders the RSP inadequate and threatens to impede and delay the relicensing efforts for both projects by failing to inform both the NEPA analysis and the requirements for Maine 401 water quality certification.

**Specific Comments**

Operational Data

The operational data provided with the RSP[5] does not fulfill project information needs. The data provided includes minimum, average and maximum impoundment water levels, minimum, average and maximum flows through the turbines, and minimum, average and maximum "waste" flows[6] on a daily basis. These data are inadequate to determine the relationship between impoundment levels and water released, compliance with license terms and conditions, or other analyses required to establish flow requirements for future operations. Reporting at least hourly data will inform decisions regarding impoundment levels that have been amply shown to be problematic. Daily reports are inadequate when the flow requirements change during the course of the day. A prime example of this are the minimum flows to support whitewater activities that occur from May 1 to October 1 between the hours of 8:30 a.m. and 5:00 p.m.[7] It should also be noted that the minimum time of restoration from generator trip events is a little over an hour so reporting the data this way greatly minimizes the apparent magnitude of these events and may obscure compliance issues. Since there is no USGS flow gage installed between Pittston Farm on the North Branch of the Penobscot and the gage downstream on the main Stem of the Penobscot at West Enfield, operational data is the only available source of this data.

TU strongly supports the comments of the National Marine Fisheries Service (NMFS) reiterating their request for hourly data that it had requested from Brookfield months ago.[8] Their filing also requests 60 days additional time to file comments on the RSP in order to review the data when it is provided. TU strongly supports this request as well, and believes in the long term, it will improve the relicensing to stay on schedule, not delay it. Brookfield controls its projects from its operations center located in Marlborough MA. In both instances where TU reported low flow excursions to FERC Compliance[9] and Brookfield responded with information, it was readily apparent that Brookfield has operational data available on at least a second-by-second basis. We have attached these reports[10] as Attachments A and B to illustrate the granularity of data that Brookfield has available. Given the apparent availability of

[5] RSP, Appendix X, Daily Operations Data.

[6] Please note the use of the term "Waste Flows." These flows serve to water Ripogenus Gorge to provide additional fishing opportunities, a designated project use under Maine environmental statutes. 100 cfs is a project requirement from July 1 to September 30 each year.

[9] TU letter Subject: Maine Council of Trout Unlimited Report of Observed Low Flow Events for the Ripogenus Project (P-2572) dated September 21, 2022; TU letter Maine Council of Trout Unlimited Amplifying Report for Observed Low Flow Events for the Ripogenus Project (P-2572) dated January 5, 2022.

[10] Brookfield letter Subject: Ripogenus Project, FERC No. 2572; Trout Unlimited Minimum Flow Complaint dated October 14, 2021; Brookfield Letter Subject: Ripogenus Project, FERC No. 2572; Trout Unlimited Minimum Flow Complaint dated March 10, 2022.

this higher resolution flow data, providing it would be at a minimal cost, and it will better inform an analysis of project effects on intra-day reservoir and downstream flow fluctuations.

NMFS Flow Studies

In addition, these data will inform the vital three flow-related studies requested by NMFS: Study to Evaluate Project Effects on River Temperature in West Branch and Mainstem Penobscot River, Study to Evaluate the Effects of Operating the Penobscot Mills and Ripogenus Dams on the Hydrology of the West Branch and Mainstem Penobscot River Using an Indicators of Hydrologic Alteration Model, and Study to Evaluate Future Flow and Water Temperature Scenarios. These studies and the analysis they include are necessary to assess current project effects and inform potential future project operation. Studies of this type were not done in the past: past studies were oriented on flow in Ripogenus Gorge or were concerned with operating minimum flows, as opposed to time studies centered on the effects of flow and flow fluctuations on aquatic habitat downstream of McKay Station. The effects of flow on the performance of the Holbrook side channel spawning and nursery area have not been studied.

The applicant's proposed Historical Operations Data Assessment Study centers on demonstrating compliance with current license terms and conditions and will not provide the data or analysis required to assess the effects of flows on the aquatic environment. Brookfield takes issue with analyses that use data predicated on climate change as does the NMFS proposed Study to Evaluate Future Flow and Water Temperature Scenarios .[11] Failure of current license terms and conditions to maintain impoundment levels above Ripogenus Dam is ample reason to conduct a study that would provide data that could improve the management of impoundment levels. Rather than base decisions on climate projections, the analysis could be conducted using actual reporting of data over a more recent time period that would be in conformance with FERC guidelines and serve to inform lake level management decisions. If these studies are not included, more information will be needed for the Commission to conduct a NEPA analysis and Maine DEP to award a water quality certification.

Socio-economic Conditions

Another overarching concern with the progress of the relicensings to date involves the Socio-economic Study Request submitted by the Penobscot Indian Nation (PIN).[12] Given that both the paper mills that were operating when the last licenses were issued to the projects have since closed, it is readily apparent that the socio-economic conditions have changed drastically since the last license terms and conditions were formulated. This fact should drive re-evaluation of all aspects of the project. FERC's study plan determination must either acknowledge the change and its wide-ranging effects on many aspects of the projects or include the Socio-economic Study in its determination. The comments of economist Dr. Sharon Kline[13] supporting the study remain germane. Socio-economic analysis will need to be included in FERC's NEPA analysis. The Commission would be well served to include that study to inform its analysis.

[13] Dr. Sharon Klein Letter dated February 18, 2022, RE: Penobscot Mills (P-2458-247) and Ripogenus (P- 2572-133) Proposed Study Plan.

TU Study Requests

TU submitted study requests for two types of studies: a Ripogenus Flow Excursion Study[14] and a series of Fish Assemblage Studies[15] correlating to the reaches described in the Pre-Application Document. In its Proposed Study Plan (PSP), Brookfield stated the Historical Operations Data and Assessment Study would document any such deviations from project minimums;[16] however, the proposed study did not account for the stranding study component of our requested Flow Excursion Study. Accordingly, TU proposed a Stranding Evaluation Study in its PSP Comments[17] that we have included as Attachment C for FERC staff's convenience.

TU made two reports to FERC Compliance Division concerning low flow events that result in observed fish strandings below the project[18] that are included as Attachments D and E. FERC responded with a letter that contained a determination that the low flow events did not constitute a violation, but encouraging Brookfield to: *"…work with Trout Unlimited, the resource agencies, and Commission staff to develop a proposal to address strandings and include it in the final license application you file by September 30, 2024."*[19] TU was unaware of any action to date regarding study of stranding events below Ripogenus Dam, and queried Brookfield staff about this in an email sent March 28, 2022 included as Attachment F. Attachment G is the Brookfield response to that email. The email refers TU to another study, the Ramping Study proposed by Ed Spear, that Brookfield also declined to include in the RSP. Brookfield's RSP would provide no information to assess the known project effect of fish stranding or inform potential license conditions that may be implemented to prevent these events. Adoption of the Stranding Evaluation Study would work directly to inform a proposal to address strandings that can be included in the final license application as stated in the FERC issuance cited.

The request for the stranding study was supported by Maine Department of Environmental Protection (MDEP): "*Further, the highly variable flows downstream of the Project dam can affect habitat, including the potential for fish and other aquatic life to become stranded in ledge pools as water levels rise and fall as a result of flow variations. Of particular concern to Trout Unlimited are the station trip flows (400 cfs) and whether such flows adequately maintain 75% of the wetted area downstream of the Project, and whether sudden reduction in flows to 400 cfs cause fish to become stranded. The Department supports TU's study request as it relates to Project operational flows on the riverine habitats affected by*

*the Project."* [20] The U. S. Fish and Wildlife Service (USFWS) supported the study request as well.[21] Despite these facts, Brookfield chose not to include this study in the RSP.

At least four low flow events occurred in the late August, early September timeframe of 2021 that were photographically documented by TU[22] and included at least one stranding of a landlocked salmon and multiple macroinvertebrate strandings. Undocumented, anecdotal reports of TU members and registered Maine guides indicate that strandings occur with some frequency during the summer months and their occurrence during winter months is largely unobserved. How frequently these events are occurring is a factor to be considered, but the severity of the strandings should be considered as well and a stranding study would inform that concern, especially with regard to its effects on the Holbrook spawning and nursery area.

The 100 cfs flow directed over the sluiceway at Ripogenus Dam from July 1 to 30 September serves to alleviate stranding problems during generator trip conditions. The project could be operated using additional water from its deep gate capability as has been done in the past[23] and this could eliminate any possible stranding issues by ensuring higher constant flows. It would also provide additional aquatic habitat and fishing opportunities within the Ripogenus Gorge that is generally dewatered except for the July 1 through September 30 sluiceway flows. The capability to eliminate strandings and provide flows below Ripogenus Dam that are more 'fish friendly' clearly exists, and more information is need to improve conditions that can be provided through a combination of analysis of hourly operational data, the flow studies requested by NMFS, the Ramping Study proposed by Ed Spear, and the Stranding Evaluation Study proposed by TU. Without these, NEPA analysis of the project's effects on stranding and the development of appropriate license conditions will prove difficult.

The other TU study requests were for a series of Fish Assemblage Studies to cover all the reaches described in the PAD. The RSP does not include these studies that MDEP supported as well: "*In order to evaluate whether the impounded waters support all species of fish indigenous to those waters, the Applicant must conduct a fish assemblage study in order to draw a comparison to the fish assemblage indigenous to those waters. Typically, such studies are proposed by Maine's Department of Inland Fisheries and Wildlife; although DIFW didn't request such a study Trout Unlimited's fish assemblage study request was declined and so the Department supports TU's request here and has attached its supporting study request."*[24] It should be noted that MDEP policy for sampling is to require it for every reach affected by project operations. Given the fragmented nature of the habitat caused by the complexity of the Penobscot Mills Project dams and impoundments, ten reaches were identified and studied. The reaches each need to be informed by current fish assemblage data. Brookfield documents that in one of the reaches, an introduced species was discovered soon after a fish assemblage study

had been conducted there.[25] "*There are recent reports that smallmouth bass have become illegally introduced to the impoundment (Kevin Dunham, MDIFW, personal communication, May 2021).*" This statement refers to Table 5.4-7, Fish Assemblage Data from North Twin Impoundment (2016-2017) which does not list smallmouth bass. This underlines the need for current information.

Brookfield provided rationale for not adopting fish assemblage studies, "… *studies need not be duplicated unless there are identified data gaps, or changes in operation that may impact the fisheries resources.*"[26] TU agrees that studies do not need to be duplicated. The problem is that Brookfield has yet to produce a coherent compilation of the assemblage studies conducted for the 10 reaches the projects contain: the PAD contained a patchwork of excerpts from studies, many from the last relicensing. When TU asked for additional studies, it provided some in the form of data tables, others by reference to web location. No coherent compilation of the studies that Brookfield wants the Commission to accept as meeting 18 CFR § 5.6 has yet been produced. MDIFW notes that data gaps may exist – where they are is impossible to determine given the information that Brookfield has supplied to date. TU requests that a compilation of fisheries assemblage studies be accomplished and an assessment of data gaps be required. Appropriate fish assemblage studies would then be conducted to fill any of the gaps identified.

Brookfield goes on to state: "*Study request constitutes basic research and/or is not likely to inform the development of license conditions (Study Criteria No. 5).*" If this were so, then the FERC Pad Adequacy Review Checklist Pursuant to 18 CFR § 5.6 would not make "*Fish and aquatic resources: description and impacts*" a checklist item. The statement that follows: "*Study request does not propose a specific methodology, proposes a methodology that is untried or uncertain, or proposes a methodology that will not meet the stated objective or yield the intended results (Study Criteria No. 6)*" is ridiculous. The PAD cites numerous such studies, the methodology is well established, Brookfield itself has requested them in the past to replace more expensive radiotracking studies. These rationales are without merit. Only by analysis of the project and how it is operated in light of current fisheries data can FERC make informed decisions concerning future operations.

Again, USFWS Comments supported the TU Study Plan Requests.[27] For all the above reasons, we ask that FERC include the Stranding Evaluation Study, and the Fish Assemblage Studies needed to fill any data gaps. FERC included Fish Assemblage Studies in an information request for the Mongaup Projects described on the next page to good effect. The Mongaup River Projects involved very similar issues over fish assemblage, existing information, and the lack of data compilation.

Other Study Requests

The Ramping Study and the Creel Study requested by Ed Spear would provide additional data beyond TU's Stranding Evaluation Study and Fish Assemblage Studies.

[25] PAD, page 5-120.
[26] RSP, page 6-15
[27] USFWS letter RE: Proposed Study Plan Comments for the Ripogenus (FERC No. 2572-133) and Penobscot Mills (FERC No. 2458-247) Hydroelectric Projects dated February 18, 2022.

TU continues to strongly support the studies proposed by MDMR as essential to the ongoing restoration of the Penobscot River Watershed: Upstream Fish Passage Alternatives Study, and Downstream Fish Passage Alternatives Study.

TU supports the USFWS Study: Upstream American Eel Passage Assessment Study – Presence, Distribution, and Relative Abundance. In the RSP, the Applicant proposes *"…to utilize the eDNA methodology suggested by MDMR to evaluate the current distribution of American eels upstream of the Projects (Appendix D of this RSP).*" Brookfield states, "*This initial step will inform the relative abundance of eels upstream of the Project developments*." The presence of American eels in the watershed is well established. This is another example of Brookfield taking a study proposal that would inform the project and replacing it with one that will not.

TU supports the comments of American Whitewater and the Appalachian Mountain Club regarding the Recreation Study and the Whitewater Boating Assessment Study. There are multiple informal recreation sites that are used for fishing in the area from Ripogenus Dam to Nesowadnehunk Falls and these should be included in the study as they are directly impacted by project operations. We also agree with the need for "*an online survey, input from a stakeholder working group, and key person interviews with organizational representatives from user groups, representatives of camp owners and other recreation related interests, such as outfitters.*" The flow studies that Brookfield felt are unnecessary are key to the Whitewater Boating Assessment Study Plan and "Whitaker-type" methodology. These studies should take place in coordination with other studies Brookfield is not proposing to include: the Ramping Study, Stranding Evaluation Study and the flow studies requested by NMFS. Lack of these features in the Whitewater Boating Assessment Study is an example of Brookfield seriously weakening the ability of the study to inform the process by eliminating key components.

The current license places no restrictions on impoundment water levels that project operations have caused to remain historically low for the past two years. TU supports the diverse studies required to assess the impacts of water levels on a variety of species: Common Loon Productivity Assessment, Study to Determine Status of Impoundment Zooplankton Population and its Relationship to Larval and Juvenile Rainbow Smelt, Freshwater Mussel Survey, Terrestrial Wildlife and Botanical Resources Study, and Northern Long-eared Bat Acoustic Study.

**Recent lessons learned from another hydro relicensing**

Rather than consider the projects such as Centralia that Brookfield referenced in its PSP and that the NGOs demonstrated were not appropriate for comparison with either the Ripogenus or Penobscot Mills Projects,[28] we ask that the Commission consider some that are, these recent relicensings undertaken by Eagle Creek, LLC in New York State: Rio Project (P-9690-112), Mongaup Falls Project (P-10481-067) Swinging Bridge Project (P10482-117) - collectively, the Mongaup River Hydroelectric Projects. Like the Ripogenus and Penobscot Mills projects, these projects were relicensed at the same time. Here Eagle Creek proposed no studies and used language strikingly similar to that used by

[28] TU filing of February 10, 2022, Accession number 20220210-5189, pages 4 and 5.

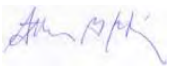
Brookfield in the PAD: "*Based on the robust nature of the study performed in support of issuing the Project's existing licenses, as well as the protection, mitigation, and enhancement (PM&E) measures associated with the Project's existing licenses, Eagle Creek believes that there is a sufficient amount of existing data for the majority of the resource areas to support the relicensing process. In particular, given that the Project's existing licenses were issued following the 1986 Electric Consumers Protection Act amendment to the Federal Power Act, the Projects underwent a comprehensive environmental analysis to establish Project-specific PM&E measures and in support of the Commission's National Environmental Protection Act analysis. This analysis was later supplemented through a number of post-license issuance study and monitoring activities associated with water quality, fish entrainment, and aquatic habitat. In addition, in support of the Rio Project's minimum flow powerhouse, additional evaluations were performed and PM&E measures were established.*"[29]

Here FERC staff recognized the deficiencies associated with the use of prior study data and its potential effect on NEPA analysis and provided for eleven studies;[30] we have included this as Attachment H. Eagle Creek ultimately included fourteen in its Revised Study Plan;[31] these included both fish assemblage and flow studies. The scope of the Mongaup River is much smaller and simpler with generating capacity of the West Branch projects only a fraction of the Ripogenus and Penobscot Mills projects. These projects are located about ten miles from Port Jervis, New York in an area that is much more developed than the West Branch and ecological concerns are reduced. Decisive action by FERC staff could similarly resolve the issues involved with study plans currently proposed for the larger and more complex Ripogenus and Penobscot Mills projects located in one of Maine's primary wilderness areas.

**Conclusions for Ripogenus – Penobscot Mills Revised Study Report**

Brookfield did not propose any specific studies in the PAD, wishing to rely on data from previous studies, an approach supportive of maintenance of the status quo. Brookfield has yet to acknowledge that major socio-economic changes have occurred since the last relicensing that have major implications for project operations both present and future: the extremely lax terms granted under the last license to Great Northern Paper are not compatible with the current conditions and have resulted in dewatering and other obvious adverse project effects. A number of the studies adopted are designed to avoid collection of data that can be used to critically assess project effects and inform potential license conditions; other study and information requests continue to be excluded outright Including critical flow studies requested by NMFS.

It should also be noted that LD 1964 was passed by the Maine Legislature on March 29, 2022 and will become law in the near future. This legislation improves the water quality classification of the West Branch below Ripogenus Dam from Class B to Class A: "*The habitat must be characterized as natural*." For Class B waters: "*The habitat must be characterized as unimpaired*." This means that waters in the Ripogenus Project will be held to a higher standard. This is another change from conditions that existed



[29] Eagle Creek Pre-application Document for the Mongaup River Hydroelectric Projects dated March, 2017, page 127.
[30] FERC Request for Studies and Additional Information for Project No. 9690-112 2, Project No. 10481-067, and Project No. 10482-117 dated July 27, 2017.
[31] Revised Study Plan for Mongaup Hydroelectric Projects dated January 10, 2018, page 2.

when the projects were relicensed some 30 years ago, and effects of the designated projects uses such as recreation, fishing, and aquatic habitat will be subject to greater scrutiny under Maine law. This is an additional reason for the Commission to act decisively to obtain the information needed to inform the projects.

Adoption of the suite of studies proposed by the stakeholders described in this filing would require the data collection that FERC needs to inform its NEPA analysis, fully evaluate project effects and licensing alternatives, inform potential license conditions, and support the timely implementation of the licensing proceeding.

Maine Council of Trout Unlimited appreciates the opportunity to comment on these critically important projects.

Respectfully,

Stephen G. Heinz

Maine TU Council FERC Coordinator

Kimberly D. Bose, Secretary
Federal Energy Regulatory Commission
888 First Street, N.E.
Washington, DC 20426

***Electronically Filed***

**Subject: Ripogenus Project, FERC No. 2572; Trout Unlimited Minimum Flow Complaint**

Dear Secretary Bose:

Great Lakes Hydro America, LLC (GLHA), licensee for the Ripogenus Project located on the West Branch of the Penobscot River in Maine, submits this letter in reply to Commission correspondence dated October 4, 2021, in which the Commission requests additional information regarding a complaint filed on September 21, 2021 by Mr. Stephen Heinz, writing on behalf of the Maine Council of Trout Unlimited (TU), that alleges two deviations from minimum flow requirements at the Project. The Commission requests that GLHA file a response to these allegations within 15 days (i.e., by October 19th) that includes:

> *(1) a description of your required flows on August 30 and September 16, 2021, based on the date, time and hydrologic year type; (2) gage data and/or project operational data indicating the actual flows prior, during, and after the alleged deviation; and (3) a description of any operational changes for August 30 and September 16, 2021.*

**August 30, 2021 low flow event**

On August 30, 2021, McKay Station (part of the Ripogenus Project) tripped offline at 12:05 pm as a result of thunderstorms in the area. The 400 cfs minimum outage flow was restored to the river within 13 minutes via the station's minimum flow system, and then the normal 2,000 cfs whitewater recreation minimum flow was restored within approximately 3.5 hours. A courtesy notification of this event was distributed to resource agencies on August 31, 2021.

> Required flows – between May 1st and September 15th, Article 402 of the Ripogenus Project license requires that minimum whitewater recreation flows of between 2,000 and 2,300 cfs be released from the Project between 0830 and 1700 hrs. on a daily basis. In a "dry" hydrologic year (such as 2021), the required minimum flows are 2,200 cfs on Saturdays and Sundays, 2,000 cfs on Mondays and Fridays, and 1,800 cfs on Tuesdays through Thursdays.
>
> During other hours of the day outside of the whitewater release time period (i.e., 1700 to 0830 hrs.), Article 402 requires a minimum flow of 1,000 cfs from June 8th through October 14th. Additionally, Article :ed "outage" minimum flows of 400 cfs when generating unit failures occur a "*with scheduled minimum flows to be resumed as quickly and practically as p es from Ripogenus Dam if necessary, but in no event in more than three days following the initial outage*".

Finally, Article 402 states that "*These specified minimum flows shall be the minimum flows for each hourly period (measured on the basis of an hourly average)*".

Since August 30th was a Monday and 2021 is a "dry" hydrologic year, Article 402 required that a minimum whitewater recreation flow of 2,000 cfs be released during the 0830 to 1700 hr. time period when the station trip occurred.

Operational data – the attached charts show Ripogenus Project outflows prior to, during, and after the August 30 low flow event and alleged license deviation.

Operational changes – On the afternoon of August 30, 2021, several hydro stations on the West Branch of the Penobscot River tripped offline during and after thunderstorm activity, including McKay Station at 12:05 pm. An investigation determined that a damaged lightning arrestor caused the outage at McKay Station. The minimum outage flow was restored to the river within 13 minutes via the station's minimum flow system (which automatically provides an emergency outage flow of more than 400 cfs), and then the 2,000 cfs whitewater recreation minimum flow was restored by 3:30 pm. The Ripogenus outflow dropped to a low of 109 cfs during the event, while the lowest hourly average outflow was 640 cfs.

Summary – although GLHA provided a courtesy notification regarding the August 30 low flow event to resource agencies (see attached), GLHA determined that the event was not reportable to the Commission as an excursion from license requirements, since the hourly average outflow did not drop below the emergency outage flow of 400 cfs. Further, the automatic minimum flow system at McKay Station functioned as designed during the event, and GLHA was able to restore river flows in a timely fashion.

**September 16, 2021 low flow event**

On September 16, 2021, McKay Station tripped offline due to a Versant Power (local utility) line disturbance. Flow was restored to the river within 5 minutes via the station's minimum flow system, and then the normal 1,000 cfs minimum flow was restored within approximately 2.5 hours. A courtesy notification regarding this event was distributed to resource agencies on September 16, 2021.

Required flows – from September 16th through October 14th, Article 402 requires a minimum flow of 1,000 cfs, except higher minimum whitewater recreation flows are required on weekends from 0830 – 1700 hrs. through October 1st.

As indicated above for the August 30th event, Article 402 allows reduced minimum "outage" flows of 400 cfs during generating unit failures at McKay Station, and it specifies that an hourly average be used as a basis for license compliance.

Since September 16th was a Thursday, whitewater recreation flows were not required that day, and only the minimum flow was being conveyed at the time of the station trip.

Operational data - the attached chart shows Ripogenus Project outflows prior to, during, and after the September 16th low flow event and alleged license deviation.

Operational changes – at 7:31 am on September 16, 2021, all of GLHA's hydro stations on the Upper Penobscot (McKay; North Twin; Millinocket; Dolby; East Millinocket; Weldon) tripped offline due to a local utility (Versant Power) line disturbance. At McKay Station, the 400 cfs emergency outage flow was restored to the river within 5 minutes via the station's

minimum flow system, and then the 1,000 cfs minimum flow was restored by 9:58 am. The Ripogenus outflow dropped to a low of 118 cfs during this event, while the lowest hourly average outflow was 508 cfs.

Summary – as with the August 30 low flow event, a courtesy notification regarding the September 16th low flow event at Ripogenus was provided to resource agencies (see attached). However, GLHA determined that the event was not reportable to the Commission as an excursion from license requirements, since the hourly average outflow did not drop below the emergency outage flow of 400 cfs. Further, the automatic minimum flow system at McKay Station functioned as designed during the event, and GLHA was able to restore river flows in a timely fashion.

In summary, the two events detailed in TU's complaint were (1) created by unforeseeable events beyond GLHA's control; (2) corrected within 13 and 5 minutes, respectively; (3) resulted in minimum flow reductions too minimal and transitory to be considered license violations; and (4) nonetheless promptly reported as a courtesy to the relevant resource agencies.

The Commission's October 4th letter also requests that GLHA provide (1) any comments received from resource agencies or other interested parties regarding the flows on these dates, and GLHA's response, and (2) the maximum ramping rates that occurred on August 30 and September 16, 2021. GLHA received no comments from the resource agencies in reply to GLHA's courtesy notifications regarding the August 30 and September 16 low flow events, and no comments or questions were received from any other stakeholders (including TU). In addition, the Ripogenus FERC license does not require flow ramping, so minimum flows were re-established as quickly as possible (consistent with the Article 402 requirement to resume scheduled minimum flows *"as quickly and practically as possible")* after each low flow event as shown in the attached graphs.

Please e-mail me at kevin.bernier@brookfieldrenewable.com or call me at (207) 951-5006 if you have any questions or need additional information.

Sincerely,

Kevin Bernier

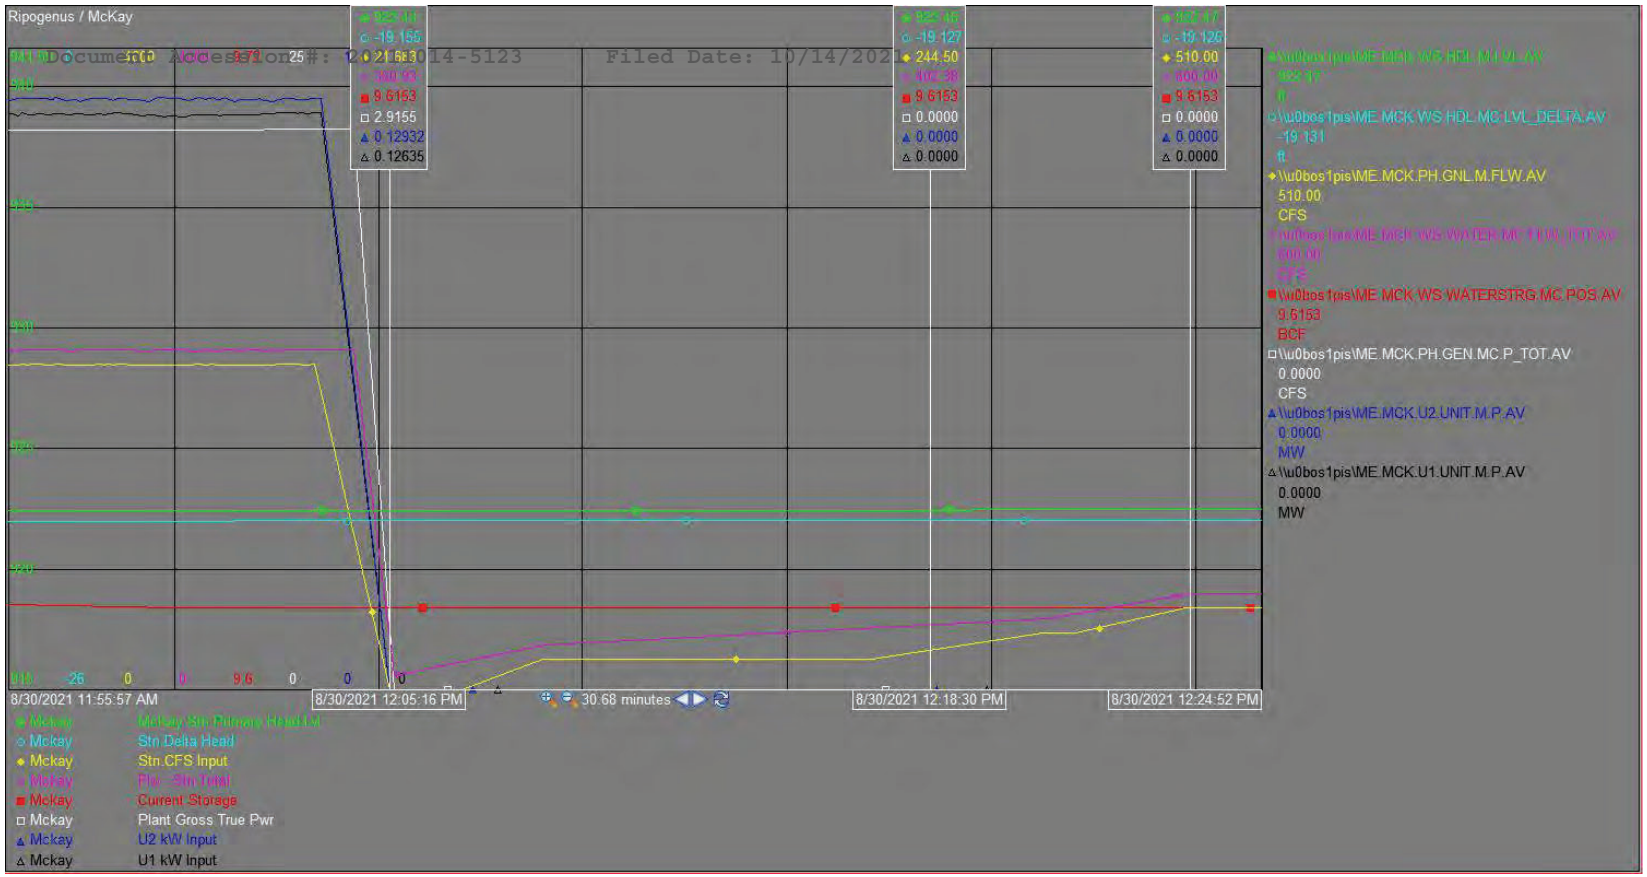
| **Subject:** | Penobscot station trips |
| **Date:** | Tuesday, August 31, 2021 3:22:00 PM |
| **Attachments:** | image001.gif |

The North Twin and Millinocket hydro stations (both part of the Penobscot Mills Project) tripped offline during yesterday afternoon's thunderstorms when a breaker tripped. Following a downstream public safety check and activation of a siren alarm, system operators deflated the inflatable flashboard system at Stone Dam, thereby re-establishing the required 2,000 cfs minimum flow at Millinocket. Outflow from the Millinocket Development dropped to a low of about 175 cfs during this approximate 14-minute flow interruption.

Article 403 of the Penobscot Mills Project license requires in part that:

> *"The licensee shall operate the Millinocket, Dolby, and East Millinocket developments in a run-of-river mode while providing an instantaneous minimum flow of 2,000 cubic feet per second (cfs) to the West Branch of the Penobscot River at Millinocket, for the protection of water quality and aquatic habitat in the Penobscot River."*



Just so you know, McKay Station (part of the Ripogenus Project) also experienced two brief station trips yesterday afternoon during the thunderstorms; however, flow was restored to the river within 15 minutes after each event via either the station's minimum flow system or by restarting a unit. The McKay Station trips are not reportable, since there was no excursion of the hourly average minimum flow requirement.

Great Lakes Hydro America, LLC is still investigating the definitive causes for these station trips, but at this point they appear to be weather-related. I will copy you on the final report to FERC, but in the meantime, please let me know if you have any questions or concerns.

| **Subject:** | Upper Penobscot system wide outage |
| **Date:** | Thursday, September 16, 2021 8:08:00 PM |
| **Attachments:** | image001.gif |

This morning at 07:31 hrs, all of Brookfield's hydro stations on the Upper Penobscot (McKay; North Twin; Millinocket; Dolby; East Millinocket; Medway; Weldon) tripped offline due to a Versant Power line disturbance. Brookfield crews have been busy all day getting the stations back online and restoring river flows as soon as practicable after making public safety checks downstream. These station trips caused disruptions in run-of-river flows at the Medway Project (FERC No. 2666) and at the Millinocket, Dolby, and East Millinocket Developments (Penobscot Mills Project, FERC No. 2458). The trip of the Millinocket Hydro Station also resulted in an estimated 15-minute deviation from that Development's 2,000 minimum flow requirement, while the trip of Weldon Station resulted in an approximate 42 minute deviation from the Mattaceunk Project's 1,674 cfs minimum flow condition. As of 13:50 hrs this afternoon, all of the stations are back online, and normal operations have resumed.

Article 403 of the Penobscot Mills license states in part that:

> "*The licensee shall operate the Millinocket, Dolby, and East Millinocket developments in a run-of-river mode while providing an instantaneous minimum flow of 2,000 cubic feet per second (cfs) to the West Branch of the Penobscot River at Millinocket, for the protection of water quality and aquatic habitat in the Penobscot River. The licensee shall at all times act to minimize the fluctuation of the reservoir surface elevations by maintaining a discharge from each of these developments so that, at any point in time, flows, as measured immediately downstream from the tailraces of the developments, approximate the sum of the inflows to the project reservoir. Run-of-river operation or minimum flows may be temporarily modified if required by operating emergencies beyond the control of the licensee, and for short periods upon mutual agreement between the licensee, the U.S. Fish and Wildlife Service, and the Maine DEP. If the run-of-river operation or minimum flow is so modified, the licensee shall notify the Commission as soon as possible, but no later than 10 days after each such incident*."

Article 402 of the Medway Project license (as amended on April 18, 2005) states:

> "*The licensee shall operate the project in a run-of-river mode to protect aquatic life and water quality in the West Branch Penobscot River. The licensee shall at all times act to minimize reservoir surface elevation fluctuation by maintaining project discharge so that, at any point in time, flows immediately downstream from the project dam approximate flows into the project reservoir. The licensee shall maintain an impoundment surface elevation*

*within six inches of 260.3 feet above mean sea level (msl) except during emergency, maintenance, and high or low flow events beyond the licensee's control, following flashboard failures. Following flashboard failures, the licensee shall maintain the impoundment level within six inches of the spillway crest and shall replace the flashboards as soon as safely possible.*

*Run-of-river operations may also be modified for short periods upon mutual agreement between the licensee and the Maine Department of Environmental Protection (DEP). The licensee shall notify the Commission as soon as possible, but no later than 10 days after each incident resulting in a change in run-of-river conditions as specified above*."

Article 403 of the Mattaceunk Project license in part states:

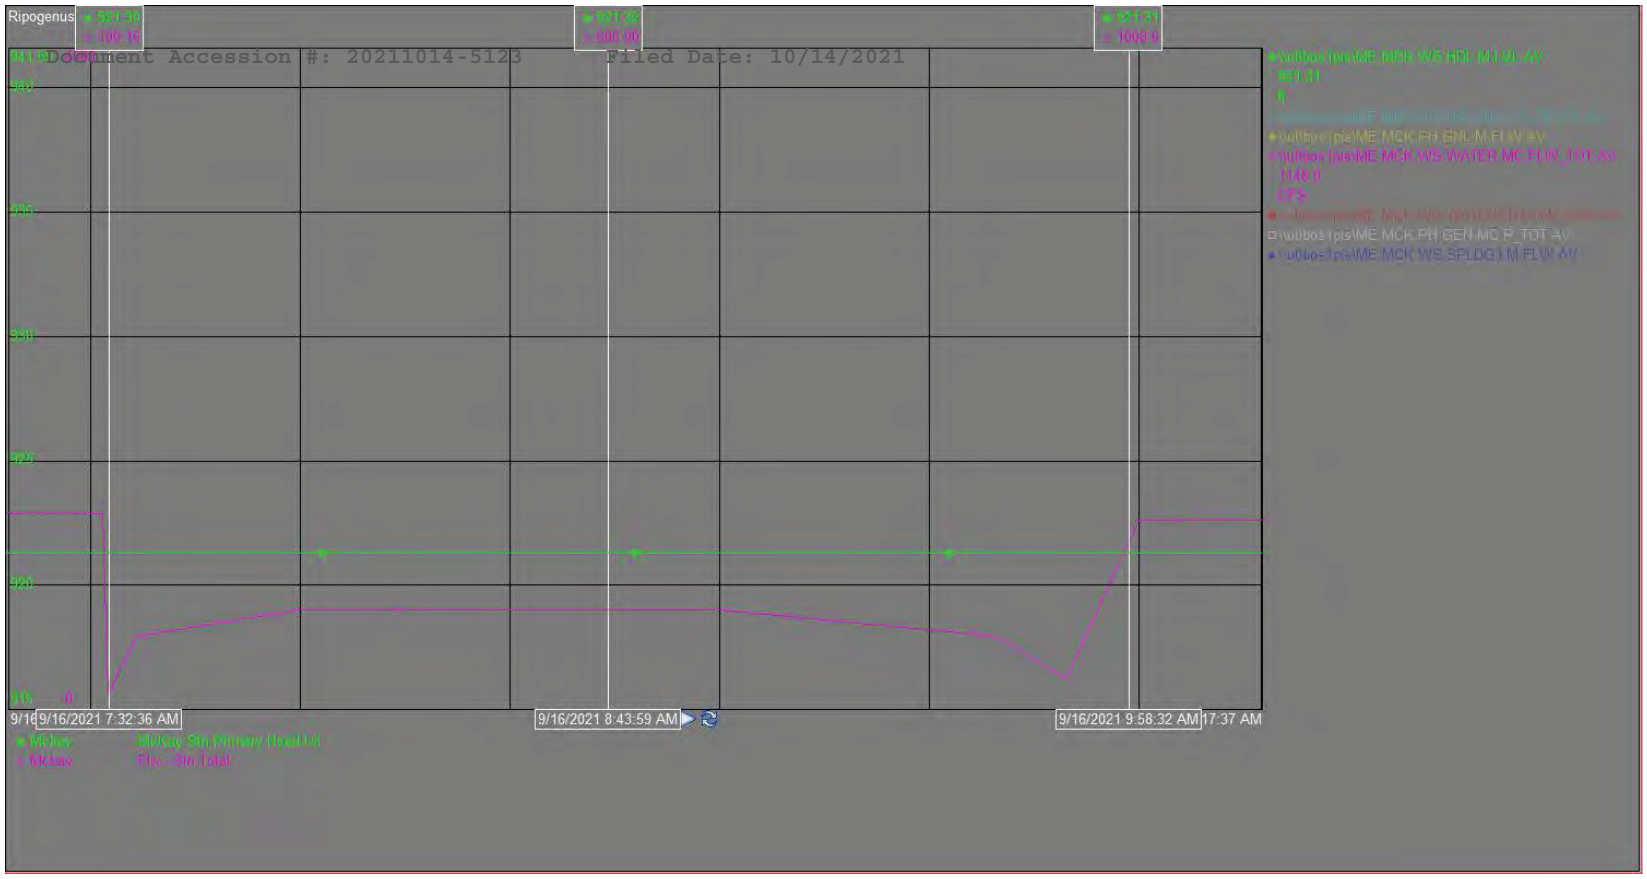
"*In addition to implementing the impoundment level requirements of Maine Department of Environmental Protection's (Maine DEP) condition A (Appendix A) and minimum flow requirements of Maine DEP's condition B (Appendix A), the licensee must operate the Mattaceunk Project in a run-of-river mode with year round use of the 4-foot-high flashboards such that average daily outflow approximates average daily inflow*."

"*For unplanned deviations lasting 3 hours or less that do not result in visible environmental effects, the licensee must file an annual report, by March 1, describing each incident that occurred during the prior January 1 through December 31 time period*."

Condition B of the Maine DEP Water Quality Certification for the Mattaceunk Project states in part:

*"Except as temporarily modified by: 1) approved maintenance activities, 2) extreme hydrologic conditions 3) emergency electrical system conditions, or 4) agreement between the Applicant, the Department, and state and/or federal agencies as appropriate, a total minimum flow of 1,674 cfs or inflow, whichever is less, and a daily average minimum flow of 2,393 cfs from July 1 through September 30 or 2,000 cfs from October 1 through June 30, shall be released from the Project to protect downstream fish and aquatic resources, unless inflow is less than the stated daily average minimum flows, in which case outflow from the Project would equal the inflow to the Project*."

As indicated above, McKay Station (part of the Ripogenus Project) also tripped offline during this event; however, the 400 cfs emergency outage flow was restored to the river within 5 minutes via the station's minimum flow system, and then the normal 1,000 cfs minimum flow was restored by 09:58 hrs. Thus, the McKay Station trip is not reportable to FERC, since there was no excursion of the Project's hourly average minimum flow requirements.



GLHA is still investigating and collecting information on this event, which will be detailed in a report to FERC within 10 days. I will copy you on this report, but in the meantime please let me know if you have any comments or questions.

# Attachment B

March 10, 2022

**FERC Project 2572**
**Article 402**

Kimberly D. Bose, Secretary
Federal Energy Regulatory Commission
888 First Street, N.E.
Washington, DC 20426

***Electronically Filed***

**Subject: Ripogenus Project, FERC No. 2572; Trout Unlimited Minimum Flow Complaint**

Dear Secretary Bose:

Great Lakes Hydro America, LLC (GLHA), licensee for the Ripogenus Project (Project) located on the West Branch of the Penobscot River in Maine, submits this letter in reply to Commission correspondence dated March 8, 2022, in which the Commission requests additional information regarding a complaint filed on January 5, 2022 by Mr. Stephen Heinz, writing on behalf of the Maine Council of Trout Unlimited (TU). Mr. Heinz alleged that Project operations on Tuesday, September 7, 2021 represented a deviation from minimum flow requirements at the Project.

On March 8, 2022 the Commission requested that GLHA file a response to this allegation within 15 days (i.e., by March 23rd) that at a minimum includes:

> *(1) gage data and/or project operational data indicating the flows prior, during, and after the alleged deviation; and (2) a description of any operational changes made on September 7, 2021. If upon compiling the requested information, you verify that one or more deviations occurred, please indicate why the deviation was not reported to the Commission and describe how you will prevent similar oversight in the future. Please also include any comments you may have received from resource agencies or other interested parties regarding the flows on these dates, and your response.*

**Minimum flow requirements**

Between May 1st and September 15th, Article 402 of the Ripogenus Project license requires that minimum whitewater recreation flows of between 2,000 and 2,300 cfs be released from the Project between 0830 and 1700 hrs. on a daily basis. In a “dry” hydrologic year (such as 2021), the required minimum flows are 2,200 cfs on Saturdays and Sundays, 2,000 cfs on Mondays and Fridays, and 1,800 cfs on Tuesdays through Thursdays.

During other hours of the day outside of the whitewater release time period (i.e., 1700 to 0830 hrs), Article 402 requires a minimum flow of 1,000 cfs from June 8th through October 14th. Finally, Article 402 states that “*These specified minimum flows shall be the minimum flows for each hourly period (measured on the basis of an hourly average).*”

**September 7, 2021 operations**

Operational changes – Shortly after the whitewater recreational flow period ended on September 7th (at 17:00 hrs.), flow from McKay Station was reduced from about 1,900 cfs to approximately 1,050 cfs (for a total Project flow of about 1,150 cfs) to conserve water during the severe drought conditions in the upper Penobscot drainage. No other operational changes were made at the time of the alleged minimum flow excursion.

Project operational data – The attached table provides operational flow data for September 7, 2021 from 17:00 hrs to midnight. No excursions from the 1,000 cfs minimum flow requirement are shown.

In summary, the September 7, 2021 event detailed in Mr. Heinz's complaint was not a minimum flow excursion and was not reportable to the Commission or the resource agencies.

Although this event did not result from a unit or station trip, the Commission has recently directed GLHA to develop a proposal to address potential fish strandings that may result from unit/station trips at the Project. (See the Commission's March 1, 2022 letter to GLHA.) GLHA will include this information in the Project's Final License Application, which will be filed with the Commission on or before September 30, 2024.

Please e-mail me at kevin.bernier@brookfieldrenewable.com or call me at (207) 951-5006 if you have any questions or need additional information.

Sincerely,

Kevin Bernier

## Stranding Evaluation Study

***Goals and Objectives***

The study will provide information regarding the potential for fish stranding associated with the Ripogenus Project. The study objective is to determine the extent and degree of danger stranding pools that occur from below the McKay Station discharge to Nesowadnehunk Falls, especially under 400 cfs generator trip events.

***Known Resource Management Goals*** (Under §5.9(b)(3) If the requester is a not a source agency, explain any relevant public Interest.)

The requestor, Maine Council of TU, is a non-governmental organization (NGO).

Maine's rivers, great ponds and wildlife are, by law, public resources. The West Branch of the Penobscot is one of the areas in Maine that TU members most prefer for fishing and other recreational activities, and thus TU has a direct interest in the waters affected by project operations, especially those from Ripogenus Dam to below Nesowadnehunk Falls.

***Background and Existing Information***

There is no existing information regarding stranding-prone areas or operational scenarios for the Ripogenus Project. This study is needed to quantify project effects on a potential source of fish mortality and injury.

***Project Nexus***

Generator trip events at McKay Station occur with some frequency and it is a matter of record that two such events occurred during the August-September timeframe of 2021 when strandings were photographically documented.[1] It is hard to image aspects of project operations that could have a more direct relationship with the welfare of aquatic organisms than immediate, drastic flow reductions.

***Methodology***

Task 1: Operational Data Review:

> Prior to conducting the field investigation, a desktop literature review will be performed to gather information on the range of flows when generator trip events are likely to occur. We anticipate that since thunderstorms occur during the summer, whitewater flows generally of 2200 – 1800 cfs would generally be in effect when the outages occur.

Task 2: Field Surveys:

> The field survey will consist of a reconnaissance level evaluation where a field crew will examine potential stranding sites in the study area at an appropriate time interval after

[1] TU Letter dated September 21, 2021, Subject: Maine Council of Trout Unlimited Report of Observed Low Flow Events for the Ripogenus Project (P-2572); TU Letter dated January 5, 2022, Subject: Maine Council of Trout Unlimited Amplifying Report for Observed Low Flow Events for the Ripogenus Project (P-2572).

spilling operations have ceased. Any accessible pools with fish stranding potential will be identified and visited shortly after the spillage event. On-ground surveys will traverse any pools and visually document fish present as well as looking for fish trapped under rocks. Information on the number and location of fish stranded will be recorded. In addition, the conditions of the study area will be photo-documented.

***Consistency with Generally Accepted Scientific Practice***

The proposed survey to document potential stranding areas is an accepted means of documenting species use in the Project area.

***Deliverables and Schedule***

The survey effort will be conducted during the summer/fall of 2022. Data and results will be included in the Initial Study Report to be filed with FERC in 2023.

***Cost and Level of Effort***

The estimated cost for the stranding evaluation is approximately $20,000. This level of effort is consistent with the size of project operations.

The Applicant may be able to combine this study with any testing of equipment and procedures ordered by the FERC Compliance Division as part of its investigation in the low flow events previously referenced, especially generator trip events. This could provide significant cost savings lowering the cost estimate provided above.

September 21, 2021

Ms. Kimberly D. Bose
Secretary Federal Energy Regulatory Commission
888 First Street, N.E.
Washington, D.C. 20426

**Via online submission to: http://www/ferc.gov (cross-filed)**

Subject: **Maine Council of Trout Unlimited Report of Observed Low Flow Events for the Ripogenus Project (P-2572)**

Dear Secretary Bose:

On behalf of its six chapters and over 2,000 members, Maine Council of Trout Unlimited (TU) submits this report of low flow events for the Ripogenus Project (P-2572). The land-locked salmon fishery below Ripogenus Dam is sustained by naturally spawned fish and nationally known for its quality. Project operations directly affect the fishing activities of our members.

On August 30, 2021, an apparent flow excursion was witnessed below Ripogenus Dam by Chewonki Campground staff and who informed TU of the event and provided photos. Such events have been occurring for the last ten years or more, but seem to be on the increase of late. The operator has generally reported them within ten days of their occurrence and we expected that to be case in this instance, but that has yet to occur. On September 13, TU called the FERC hotline and spoke with FERC official Mark Carter who explained that he would pass the information to appropriate FERC staff and that someone would be in contact with us. Hearing nothing back, we called again on September 15, and received the same assurance. On September 16, we were contacted by FERC official Alicia Burtner.[1] She explained how to report the event using FERC Online. Later that day, Chewonki Campground staff reported witnessing another low flow event. Rather than wait and file a separate report, we are including that event in this filing with the August 30 event.

To complicate matters, subsequent to the drafting of this report, Brookfield reported an excursion event that occurred on September 10, 2021.[2] This event was observed by TU contacts in the area who did not consider it problematic. It does not correlate with either of the flow events contained in this report.

**August 30, 2021 Event**

On that date, Sarah Sindo, Chewonki Campground Manager, reported that there had been a significant drop in the river similar to previous occurrences. At about noon, the river level dropped to 300-400 cfs and remained that flow until about 3pm. A thunder and lightning storm rolled through the area and there were rumblings that the outage was caused by a lightning strike. The Campground received no notification from the project operator. Prior to the event, flows at been running 1800 cfs. In further correspondence, Sarah reported that Maine Guide Mike McVey had observed both fish and macro-invertebrate strandings near the Cribworks (just downstream of Telos Bridge).

[1] Phone conversation, Stephen Heinz of TU and Alicia Burtner of FERC staff, September 16, 2021.
[2] Brookfield letter Subject: Ripogenus Project (FERC No. 2572);Whitewater Recreation Minimum Flow Excursion dated September 20, 2021, FERC Accession number 20210920-5168.

Photographs were taken that are provided on the following pages along with the location and photographer. The Big Eddy is a large, deep pool that cannot be fully dewatered because of the height at the outlet. Water levels in the photos are close to the limit of hydraulic controls.

**September 16, 2021 Event**

On this date, Sarah Sindo, Chewonki Campground Manager, reported that there had been another significant flow event that morning around 8 a.m. when she noticed the river was way down and not rising to the scheduled 1800 cfs. She looked at the Brookfield water flow website and it read 400 cfs. When Maine Guide Mike McKenzie asked her about flows, she replied that she wasn't sure what was going on. Before she shuttled him down to the Little A (base of Amberjackwockamus Falls) takeout, she looked at the website again and it read 600 cfs. She then emailed Mike Osborne of Brookfield asking what the flow was scheduled to be today because there wasn't anything specific listed. He responded: "The hydro stations all tripped offline due to a problem at the utility tie. McKay station is running on the min flow system at the moment. Not sure how long it is going to be before we can normalize. Sorry I don’t have more information, but we’re dealing with this as quickly as possible." Low flows persisted until 12:30 or 1:00.

Here is a picture that Maine Guide Kevin McKay took at the Little A takeout documenting the low flow event.

**Other Information**

The flow regime for the Ripogenus Project is complex, minimum flows are 1000 cfs[3] - for your convenience we are providing them as Attachment A as they appear in the Pre-application Document (PAD) for the project's relicensing currently in progress.

A number of flow excursions have occurred at the Ripogenus Project over the years prior to these most recent ones. For your convenience, we have listed them in the following table:

| Filed | Docket(s) | Description | Remarks |
|---|---|---|---|
| 7/15/11 | P-2572-119 | Report Minimum Flow Excursion Event at the Ripogenus Development P-2572 Dated 20110715. | Failed to open sluice gate by July 1 to provide 100 cfs through upper gorge. FERC ruled this a violation |
| 6/23/15 | P-2572-121 | 20150623 Flow Excursion due to McKay Station Outage Ripogenus Project; Compliance Article 402 under under P-2572. | 100 cfs for 63 minutes<br><br>FERC took action |

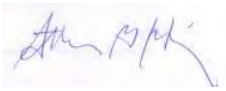
[3] Brookfield Pre-application Document for Ripogenus Project (FERC No. 2572) dated June 11, 2021, Section 4.

From information provided in response to TU questions at the scoping meeting for agencies and NGOs held September 9, repair crews must come from Millinocket to restore required flows after an excursion. Manual operations are required. TU believes that based on past outages, over two hours is the minimum time required to restore flows.



**Conclusions and Request**

TU finds it troubling that these flow events continue to occur - even more so when they are not reported as remains the case for the August 30 and September 16 events and apparently for the June 19, 2017 event noted above. Since the campground is not manned and use is minimal during the winter months, we wonder how many unreported excursions have occurred over the years. Of additional note: the Commission required follow-up on the June 13, 2015 excursion that was reported by Brookfield's letter that we have included as Attachment B.[4] While this action may have corrected problems with the minimum flow system, low flow events continue to be a problem for the Ripogenus Project and the minimum time need to restore target flows appears to be over two hours with adverse consequences to fish and other aquatic organisms as well as to the fishing and whitewater rafting activities.

TU requests that the Commission investigate these unreported flow events; determine magnitude, timing, and cause; require the operator to provide any required reports; and take appropriate follow-up action. License conditions exist to balance project harms and benefits. In the absence of compliance with project terms and conditions, it must be assumed that project operations do more harm than good.

Maine TU Council appreciates the Commission's attention to this matter.

Sincerely and respectfully,

Stephen G. Heinz
Maine TU Council FERC Coordinator

## 4.4 Project Operations

The Ripogenus and Penobscot Mills Projects are operated as a combined system. A diagram depicting the current operational requirements for the Projects and the associated flow of water through the system is provided as Figure 4.4-1.

### 4.4.1 Ripogenus Project

As established through the previous relicensing, the Ripogenus Project operates as a store-and-release development with an annual seasonal drawdown that allows for management of water levels and flows downstream of the Ripogenus Project, including the downstream reaches of the West Branch and the mainstem of the Penobscot River. As recognized by the stakeholders involved in the previous relicensing, the operations of the Ripogenus Project serve as a re-regulating impoundment that works in coordination with the upstream Storage Project (FERC No. 2634) and the downstream North Twin and Millinocket Lake Developments (of the Penobscot Mills Project) to maximize the balancing of downstream flows and water levels in support of flood control, public safety, dam safety, supplemental flows during seasonal low flow periods, fish spawning and migration, recreation, whitewater boating, water quality, local electrical grid stability, and baseload renewable energy generation. In particular, the size of the Ripogenus impoundment in combination with the Project's operational flexibility provides the storage resource that minimizes the detrimental effects of natural high and low water periods within the larger Penobscot River basin.

The Ripogenus Project impoundment, in combination with the upstream Storage Project and the downstream North Twin and Millinocket Lake developments, provide stakeholders of the larger Penobscot River basin with a valuable re-regulating tool to manage river flows in support of stakeholder interests. Without the existing storage capacity and operational flexibility developed by the stakeholders through the previous relicensings, the basin and downstream river users would be routinely subject to higher variable flows throughout the system – including flooding, public safety, dam safety and environmental impacts throughout the downstream reaches.

The Project's impoundment is managed on an annual cycle to dampen the variability and occasional extremes of seasonal precipitation and runoff through storage within the impoundment.

*Copyright © 2021, Great Lakes Hydro America, LLC. All rights reserved.*

This storage allows for continuous flows to downstream aquatic habitat and spawning areas within the West Branch and the mainstem of the Penobscot River during times of lower inflows to the system. In addition, the storage allows flows from the West Branch to be reduced during higher seasonal flow periods when the combined flows from the East and West Branches have the potential to adversely impact human life, property, and environmental resources downstream along the mainstem Penobscot River.

Normal full pond elevation of the Ripogenus impoundment is 941.6 feet with a maximum drawdown of 44 feet (based on operational limitations of the Project). During normal operations, the Ripogenus impoundment is maintained between normal full pond elevation (941.6 feet) following seasonal inflow to the impoundment and a target elevation of 913.6 feet prior to the seasonal inflow, which equates to a target seasonal drawdown range of 28 feet.

During normal operations and normal inflow years, the Ripogenus impoundment elevation is held relatively stable during the summer months and is gradually drawn down starting in the fall with a target low elevation by late winter in anticipation for the spring thaw and freshet. In the spring, the Ripogenus impoundment elevation rises based on inflows from the upstream Storage Project, spring thaw, and precipitation with the goal to reach normal full pond elevation by late spring. In this capacity, as compared to allowing these inflows to be released to the downstream reaches and potentially causing flooding, public safety, and dam safety impacts, the Project acts as a re-regulating impoundment in support of providing a more constant flow for downstream resources and impacts.

In support of managing the impoundment levels and downstream flows, GLHA tracks seasonal inflows to the impoundment (e.g., through snow surveys). As recognized by Project stakeholders, even with significant efforts to estimate inflows to the impoundment, the system is subject to natural variability in regional precipitation, which results in events such as 10-year and 100-year storm events, as well as low inflow or drought events (e.g., 2002 and 2020-2021).

Under the Project's existing license, GLHA is provided the flexibility to provide the required minimum flows in support of aquatic and riverine resources, while providing the tools to help

*Copyright © 2021, Great Lakes Hydro America, LLC. All rights reserved.*

reduce the potential impacts (e.g., flooding, public safety, and dam safety) resulting from higher water years.

Pursuant to Article 401 of the existing license, a minimum flow of 100 cfs is released from Ripogenus Dam into the bypassed reach (Upper Gorge) from July 1 through September 30 annually. Consistent with the August 19, 1997 FERC order approving and modifying the Water Management Plan, the minimum flows into the Upper Gorge are released through the sluice gates at the north end of the dam. During the remainder of the year, a minimum flow of 12 cfs is provided through leakage from Ripogenus Dam into the Upper Gorge. Releases from the Ripogenus Project enter the West Branch and flow 21 miles downstream (from McKay Station) into Ambajejus Lake, which is part of the North Twin Development of the Penobscot Mills Project.

**Figure 4.4-1**
**Operational Requirements for the Ripogenus and Penobscot Mills Projects**

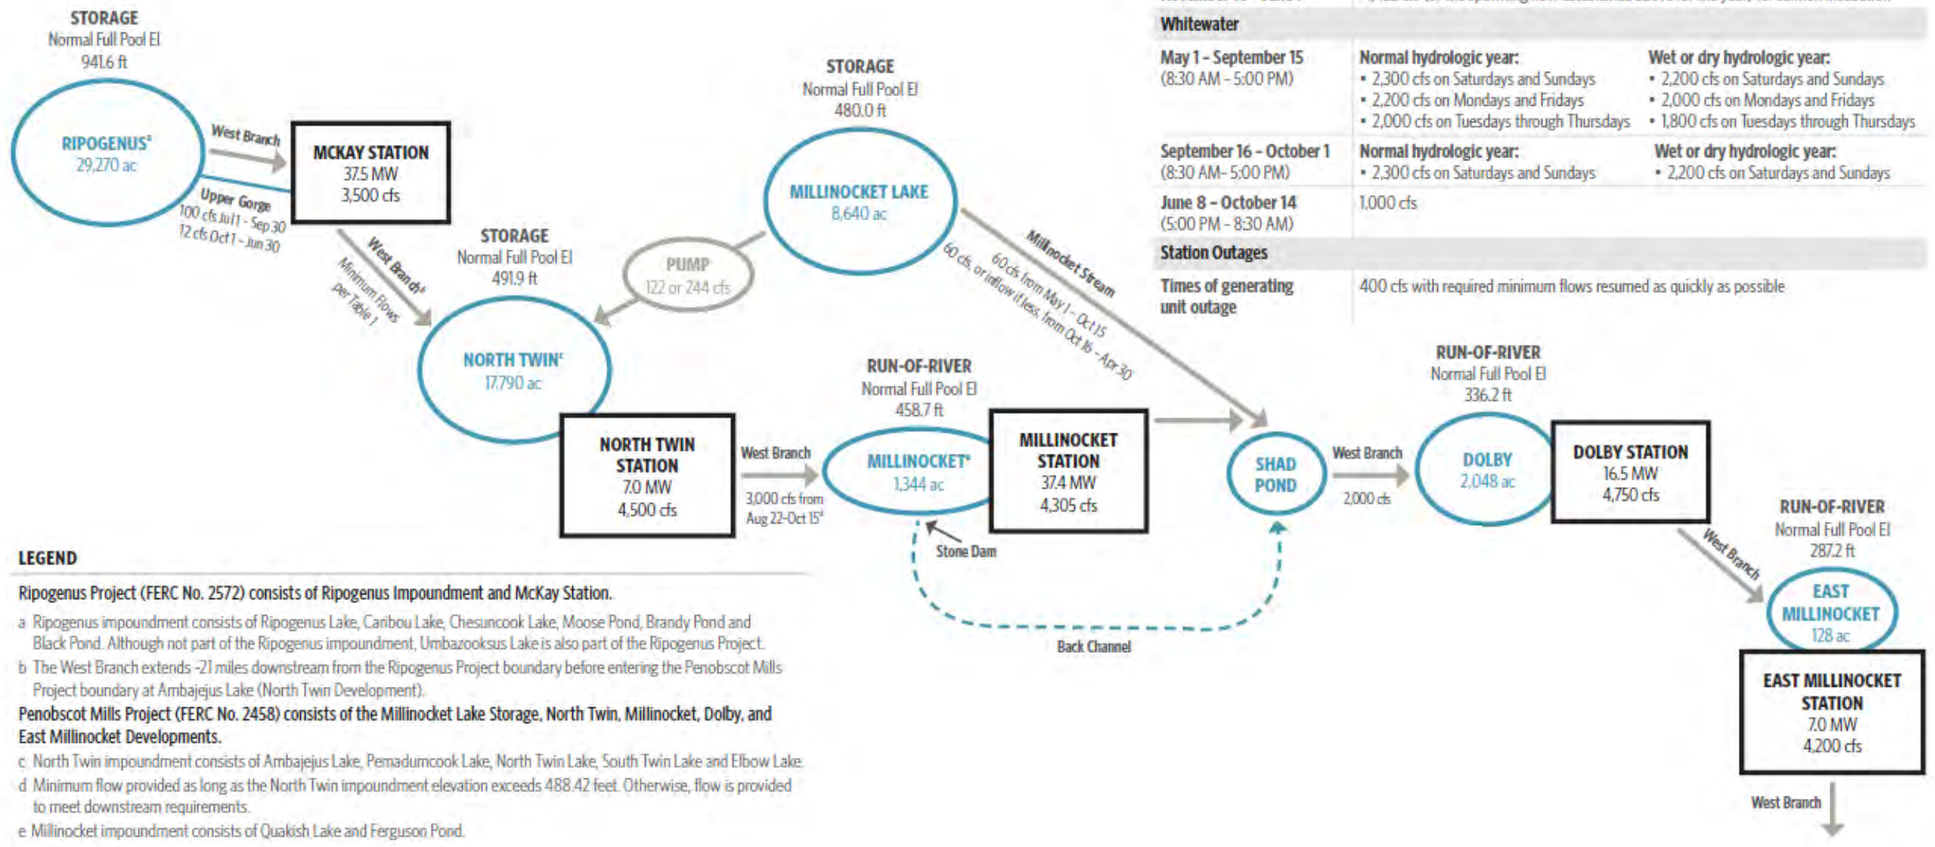

**Table 1:** McKay Station Minimum Flows

| PERIOD | MINIMUM FLOW REQUIREMENT | |
|---|---|---|
| **Fish Spawning or Incubation** | | |
| September 16 – October 14 | 1,000 cfs | |
| October 15 – November 15 | ≥1,422 cfs or inflow, but not less than 1,300 cfs for salmon spawning | |
| November 16 – June 7 | >1,422 cfs (or the spawning flow established above for the year) for salmon incubation | |
| **Whitewater** | | |
| May 1 – September 15 (8:30 AM – 5:00 PM) | **Normal hydrologic year:**<br>• 2,300 cfs on Saturdays and Sundays<br>• 2,200 cfs on Mondays and Fridays<br>• 2,000 cfs on Tuesdays through Thursdays | **Wet or dry hydrologic year:**<br>• 2,200 cfs on Saturdays and Sundays<br>• 2,000 cfs on Mondays and Fridays<br>• 1,800 cfs on Tuesdays through Thursdays |
| September 16 – October 1 (8:30 AM- 5:00 PM) | **Normal hydrologic year:**<br>• 2,300 cfs on Saturdays and Sundays | **Wet or dry hydrologic year:**<br>• 2,200 cfs on Saturdays and Sundays |
| June 8 – October 14 (5:00 PM – 8:30 AM) | 1,000 cfs | |
| **Station Outages** | | |
| Times of generating unit outage | 400 cfs with required minimum flows resumed as quickly as possible | |

**LEGEND**

**Ripogenus Project (FERC No. 2572) consists of Ripogenus Impoundment and McKay Station.**

a Ripogenus impoundment consists of Ripogenus Lake, Caribou Lake, Chesuncook Lake, Moose Pond, Brandy Pond and Black Pond. Although not part of the Ripogenus impoundment, Umbazooksus Lake is also part of the Ripogenus Project.

b The West Branch extends ~21 miles downstream from the Ripogenus Project boundary before entering the Penobscot Mills Project boundary at Ambajejus Lake (North Twin Development).

**Penobscot Mills Project (FERC No. 2458) consists of the Millinocket Lake Storage, North Twin, Millinocket, Dolby, and East Millinocket Developments.**

c North Twin impoundment consists of Ambajejus Lake, Pemadumcook Lake, North Twin Lake, South Twin Lake and Elbow Lake.

d Minimum flow provided as long as the North Twin impoundment elevation exceeds 488.42 feet. Otherwise, flow is provided to meet downstream requirements.

e Millinocket impoundment consists of Quakish Lake and Ferguson Pond.

*Copyright © 2021, Great Lakes Hydro America, LLC. All rights reserved.*

Article 402 of the existing license requires minimum flows downstream of McKay Station into the West Branch as specified in Table 4.4-1. These flows may be temporarily modified if required by operating emergencies beyond the control of the Licensee and for short periods upon agreement between the Licensee and the Maine Department of Environmental Protection (MDEP) and Land Use Planning Commission (LUPC). Minimum flows may also be modified (to outflow approximates inflow) if required by hydrologic conditions beyond the control of the Licensee upon mutual agreement between the Licensee, USFWS, MDEP, LUPC, and MDIFW. Consistent with the August 19, 1997 FERC order approving and modifying the Water Management Plan, changes in flows below McKay Station are accomplished through the turbines; however, if necessary, GLHA will open a gate at Ripogenus Dam to augment flows.

**Table 4.4-1**
**Minimum Flow Requirements downstream of McKay Station for the Ripogenus Project[1]**

| Date Range | Minimum Flow Requirement |
|---|---|
| ***Fish Spawning or Incubation*** | |
| September 16 – October 14 | 1,000 cfs to facilitate drawdown of the North Twin impoundment (part of the Penobscot Mills Project) |
| October 15 – November 15 | At least 1,422 cfs or inflow, but not less than 1,300 cfs[2] for salmon spawning |
| November 16 – June 7 | Greater than 1,422 cfs (or the spawning flow established above for the year)[2] for salmon incubation |
| ***Whitewater*** | |
| May 1 – September 15<br>(8:30 AM – 5:00 PM) | Normal hydrologic year[3]:<br>• 2,300 cfs on Saturdays and Sundays<br>• 2,200 cfs on Mondays and Fridays<br>• 2,000 cfs on Tuesdays through Thursdays<br>Wet or dry hydrologic year[3]:<br>• 2,200 cfs on Saturdays and Sundays<br>• 2,000 cfs on Mondays and Fridays<br>• 1,800 cfs on Tuesdays through Thursdays |
| September 16 – October 1<br>(8:30 AM– 5:00 PM) | Normal hydrologic year[3]:<br>• 2,300 cfs on Saturdays and Sundays<br>Wet or dry hydrologic year[3]:<br>• 2,200 cfs on Saturdays and Sundays |
| June 8 – October 14<br>(5:00 PM – 8:30 AM) | 1,000 cfs |
| ***Station Outages*** | |
| Times of generating unit outage | 400 cfs with scheduled minimum flows identified above in table to be resumed as quickly as possible by releases from Ripogenus Dam if necessary but in no event in more than three days following the initial outage |

[1] Minimum flows shall be the minimum flows for each hourly period measured on the basis of an hourly average.
[2] Flows to be established each year in consultation with the USFWS and MDIFW.
[3] The whitewater flow for each month from May through September is determined on the first day of each month based on an analysis of Total Available Water as described in the Water Use Plan in the application for new license filed with the Commission on December 17, 1991. The determination of "wet," "normal," or "dry" shall remain constant during the month based on the first day of the month classification. The range of "normal" available water

*Copyright © 2021, Great Lakes Hydro America, LLC. All rights reserved.*

represents the expected available water during normal hydrologic conditions. It is defined as the range between x-s and x+s, where "x" is the mean value and "s" is the standard deviation. Based on a statistical analysis, total available water would be expected to be within this "normal" range two-thirds of the time and outside of this range ("wet" or "dry" years) one-third of the time.

Pursuant to the February 20, 2003 FERC order approving the Habitat Improvement Plan under Article 406 of the existing license, GLHA manages flows from the West Branch into the "Holbrook Side Channel." The Holbrook Side Channel is a 1,400-foot-long channel located approximately 1.7 RM downstream from the Ripogenus Dam in which flow is diverted from the West Branch for landlocked salmon and brook trout spawning and rearing. Flow from the channel re-enters the West Branch approximately 1,000 feet downstream. Flows into the channel are controlled through two pipes, one of which is equipped with a valve that can be opened or closed to increase or reduce flow from the West Branch into the channel. Flows into the channel range from between approximately 35 and 65 cfs during normal operating conditions, depending on the amount of flow in the West Branch. Around June 1, GLHA closes the valve to reduce flow into the channel (for landlocked salmon and brook trout fry emergence and production). Around October 15, GLHA opens the valve to increase flow into the channel (for landlocked salmon and brook trout spawning).

### 4.4.2 Penobscot Mills Project

The five developments that comprise the Penobscot Mills Project are operated as an integrated system, primarily based on flows received from the Ripogenus Project. The two store-and-release developments (Millinocket Lake Storage and North Twin) are located upstream of the run-of-river developments (Millinocket, Dolby, and East Millinocket). The North Twin impoundment receives flow from the Ripogenus Project. The Millinocket Lake Storage Development is located on Millinocket Stream, which enters the West Branch downstream of the Millinocket Development. Water from Millinocket Lake is either pumped into Ambajejus Lake (part of the North Twin Development), which subsequently passes through the North Twin and Millinocket powerhouses, or it is released into Millinocket Stream, which enters the West Branch downstream of the Millinocket Development.

**FERC Project No. 2572**
**Article 402**

Secretary Kimberly S. Bose
Federal Energy Regulatory Commission
Mail Code: DLC, HL-11.2
888 First Street, N.E.
Washington, D.C. 20426

Dear Secretary Bose:

**RE: Ripogenus Project 2572, Article 402 Compliance;**
**Follow-up to June 13, 2015 Flow Excursion due to McKay Station Outage**

On June 23, 2015, Great Lakes Hydro America, LLC (GLHA), licensee for FERC Project No. 2572-ME (Ripogenus) in Maine, submitted an excursion report to the Commission to report an approximately one-hour reduction in outflow from the Project's McKay Station to the West Branch of the Penobscot River. As explained in the letter, the excursion occurred on June 13, 2015, due to a transmission line pole cross arm failure and a subsequent malfunction of the Station's minimum flow system (which is designed to ensure an outflow of 400 cfs during a station outage). GLHA committed in the letter to investigating and troubleshooting the cause of the minimum flow system malfunction and to update the Commission with any additional corrective measures after the malfunction is fully identified and rectified. The June 23 letter further stated that a sluice gate at Ripogenus Dam would be left open until GLHA is confident that the minimum flow system will function properly and provide the required 400 cfs flow during any subsequent station outages.

In its August 11, 2015 response, the Commission indicated that the June 13 minimum flow deviation would not be considered a violation of Article 402 of the Ripogenus Project license. However, in regards to the minimum flow system malfunction, the Commission also requested:

> *"Once you identify the cause(s) of the system malfunction and rectify the problem, you will update the Commission with the results of any additional corrective measures".*

On December 28, 2015, GLHA notified the Commission (by voice mail to Mr. Raymond James) that the issues with the minimum flow system malfunction had been fully rectified and verified through testing. As a result, the open sluice gate at Ripogenus Dam was shut on December 22. In his December 31 reply, Mr. James requested that GLHA submit a written verification e-filing to the Commission that the McKay Station minimum flow system malfunction issues have been addressed.

Following the investigation of the minimum flow system malfunction, GLHA undertook several corrective measures:

1. All of the minimum flow brake pads on Units 1 & 2 at McKay Station were replaced, and the brake system components on all three generating units were cleaned and lubricated.

2. Limit switches on Units 1 and 2, which were found to intermittently malfunction, were adjusted.

Brookfield

Brookfield Renewable Energy Group
New England Regional Operations Center
Great Lakes Hydro America, LLC
1024 Central Street
Millinocket, Maine 04462

Tel 207.723.4341
Fax 207.723.3948
www.brookfieldrenewable.com

3. Several air leaks in the minimum flow system were sealed.

4. A consultant was retained to verify that all PLCs (Programmable Logic Controllers) were correctly set up to ensure that the minimum flow system operates as intended.

5. Air pressures to the minimum flow system were adjusted to the correct operating pressures.

6. A preventative maintenance sheet was developed for annual minimum flow system testing and verification.

On December 22, 2015, following these corrective measures, the minimum flow system was thoroughly tested during a mock station outage, and it performed properly and as intended. Units 1 & 2 held at 13% wicket gate opening and Unit 3 held at a 7% opening during the outage (as intended with the minimum flow braking system), which provided a flow of ~390 cfs through the turbines. This flow, together with the 12 cfs estimated leakage flow from Ripogenus Dam, resulted in a flow of just over 400 cfs from the Project.

Following this testing and verification that the minimum flow system works properly, the sluice gate was closed later in the day on December 22, 2015.

Please feel free to contact me at (207-723-4341, x118) if you have any questions or comments.

Sincerely,

Kevin Bernier

Subject: **Maine Council of Trout Unlimited Amplifying Report for Observed Low Flow Events for the Ripogenus Project (P-2572)**

Dear Secretary Bose:

On behalf of its six chapters and over 2,000 members, Maine Council of Trout Unlimited (TU) submits this report in amplification of the report of low flow events for the Ripogenus Project (P-2572) that TU filed on September 21, 2021.

**Background**

On August 30, 2021, an apparent flow excursion was witnessed below Ripogenus Dam by Chewonki Campground staff who informed TU of the event and provided photos. Such events have been occurring for the last ten years or more, but seem to be on the increase of late. The operator has generally reported them within ten days of their occurrence and we expected that to be case in this instance, but that did not occur. On September 13, TU called the FERC hotline and spoke with FERC official Mark Carter who explained that he would pass the information to appropriate FERC staff and that someone would be in contact with us. Hearing nothing back, we called again on September 15, and received the same assurance. On September 16, we were contacted by FERC official Alicia Burtner.[1] She explained how to report the event using FERC Online. Later that day, Chewonki Campground staff reported witnessing another low flow event. Rather than file a report of a separate event TU filed the report of the September 16 event with our report of the August 30 event.

To complicate matters, subsequent to the drafting of that report, Brookfield reported an excursion event that occurred on September 10, 2021.[2] It does not correlate with either of the flow events contained in our September 21, 2021 report. The Commission subsequently ruled that the September 10 flow event did constitute a license violation.[3]

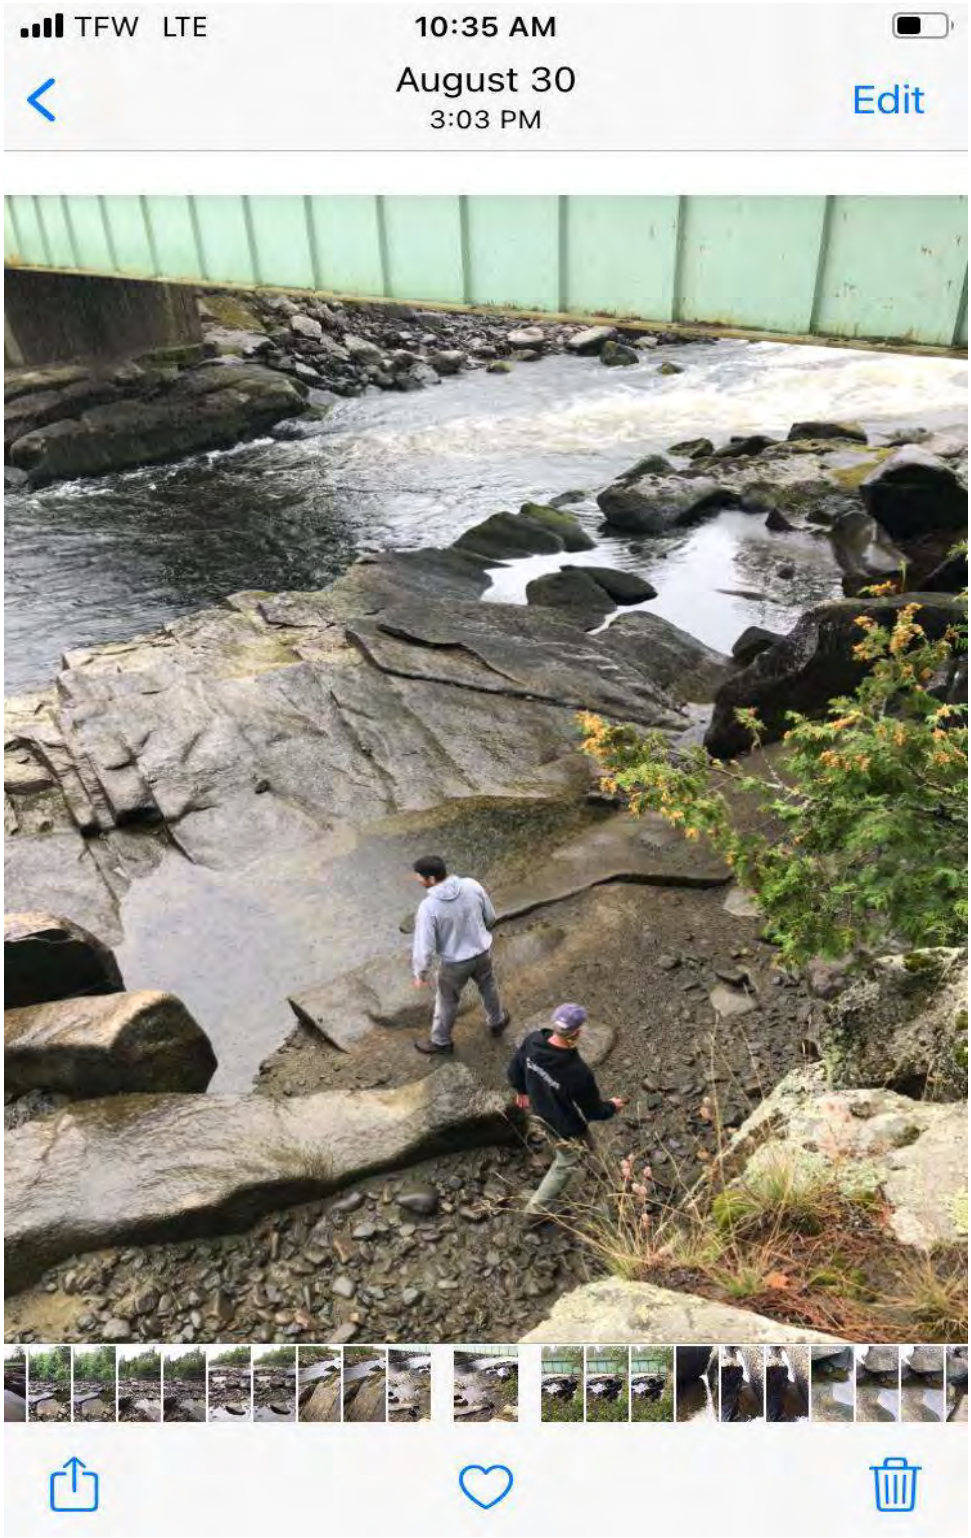
Miles Puleio, who fishes and kayaks on the West Branch of the Penobscot River, participated in the proposed Study Plan Teleconference for the Ripogenus and Penobscot Mills project relicensings held on December 16, 2021.[4] Topics discussed included the study plan request submitted by TU for a Ripogenus

[1] Phone conversation, Stephen Heinz of TU and Alicia Burtner of FERC staff, September 16, 2021.

[2] Brookfield letter Subject: Ripogenus Project (FERC No. 2572); Whitewater Recreation Minimum Flow Excursion dated September 20, 2021, FERC Accession number 20210920-5168.

[3] FERC letter of November 8, 2021, Subject: Violation of Whitewater Recreation Flow – Article 402.
*"… at the Ripogenus Hydroelectric Project No. 2572, located on the West Branch Penobscot River in Piscataquis County, Maine. For reasons discussed below, we find you in violation of Article 402 of your project license."*

[4] Brookfield letter of December 8, 2021, Subject: Ripogenus Hydroelectric Project (FERC No. 2572-133) Penobscot Mills Hydroelectric Project (FERC No. 2458-247) Proposed Study Plan Meeting Agenda



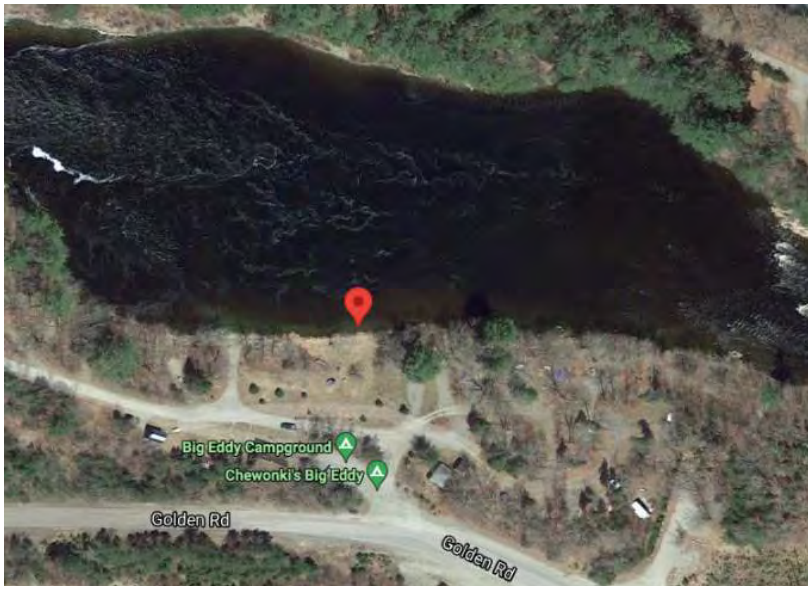
Flow Excursion Study that would conduct a planned low flow event with observers positioned downstream of McKay Station to see if strandings occurred. Miles contacted TU to say that he had a fish stranding photo taken during the August 30 event and macro-invertebrate stranding photos for the September 16 event. He also reported an additional low flow event that occurred on September 7, 2021 that we will address later in this document.

**Strandings Photos**

The photographs below were taken by Miles on the north bank of the West Branch of the Penobscot River immediately below Telos Bridge on August 30, 2021. He has verified that the date/time markings are correct. This map shows the exact location where the photos were taken:

The photo that follows on the next page was taken by Miles looking down at the river from the bank above and includes fellow kayakers Riley Adams and Bill Dallam.

Subsequent photos are of the pool to their immediate left. Please note that the place where they are pictured standing had been running at whitewater flows prior to the event that cause that reach to be classified as Class 5 whitewater. Rapid drops in water level have are likely to strand fish. Miles kayaked to check for other stranded fish and observed about 8 - 12 other stranded fish during this event with four fish specifically noted in a pool just above Holbrook. It is difficult to see stranded in pools, more difficult to photograph them.



Here is a photo of the pool, it is difficult to see the stranded fish that it contains.

Here is the stranded fish. It is a landlocked salmon estimated at 12-13” in length. It was likely stranded in the pool for about three hours.

Here is are the map location and photos of a stranded macro-invertebrates taken during the September 16 event as video that may be viewed at https://drive.google.com/file/d/1KNQf-OzvoG2Lcrq_F2rdDitD3JyHB2I5/view?usp=sharing Numerous other stranded macro-invertebrates were also observed in the vicinity of the campground.

**Additional Low Flow Event**

Miles also reports that a previously unreported low flow event occurred on September 7. This flow was lower than evening flows had been and is estimated to be 800 cfs or less. This occurred at about 6:30 p.m. and persisted for about an hour. The photo that follows the map was taken looking downstream from where Holbrook joins the West Branch on the south bank. The location where the photo was taken is depicted on this map:

The following summary of incidents is provided for clarity:

- August 30 - reported by Maine TU Council filing dated September 21, 2021
- September 7 - previously unreported event (photo immediately above)
- September 10 - reported by Brookfield, ruled a license violation by FERC
- September 16 - reported by Maine TU Council filing dated September 21, 2021

**Ongoing FERC Action**

The photos provided afford additional verification of the August 30 and September 16 events and documents both fish and macro-invertebrate strandings. FERC established a sub-docket for these incidents: P-2572-134. It is assumed that the Commission is continuing to investigate the low flow events of August 30 and September 16, 2021; we assume that the information contained in FERC's filing of December 29, 2021 (bold supplied) will be considered when it rules whether these events constitute license violations as well:

"*Docket(s): P-2572-000*
*Filing Type: Part 12 Consultant Safety Inspection Reports*
*Description: Brookfield Renewable submits 11th Part 12D Independent Consultant's Safety Inspection Report and associated* ***Potential Failure Mode Analysis Addendum for the Ripogenus Project*** *under P-2572. "*

This casts doubt into our minds as to if the corrective actions Brookfield took in 2015[5] to prevent flows below 400 cfs that we noted in our initial report were fully effective.

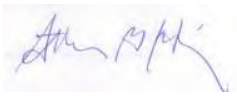
**Additional Considerations**

FERC Project Officer commented during the PSP teleconference previously referenced that TU's proposed Ripogenus Flow Excursion Study should not be conducted until it the frequency of such events were determined. Apparently, there were at least four events that occurred in a three-week period during August and September of 2021. This amplifying report documents that strandings did occur incident to the August 30, 2021 event and September 16, 2021 event. This report confirms that low flows associated with generator shut downs cause stranding events lasting for over an hour at the least due to travel time for maintenance crews from Millinocket to McKay Station, and were of a longer duration in these specific incidences. We hope that the operator will take the consequences of these events to aquatic organisms into consideration and include the requested Ripogenus Flow Excursion Study in its Revised Study Plan. While these events are not of the magnitude of dewatering of the Upper Madison River in Montana due to a dam gate malfunction,[6] these events have been occurring for some time and studies to determine the magnitude of their impacts below Ripogenus Dam are long overdue.

**Conclusions and Request**

Maine TU Council appreciates the Commission's continuing attention to the low flow events below Ripogenus Dam.

We request a copy of the Brookfield Renewable 11th Part 12D Independent Consultant's Safety Inspection Report and associated Potential Failure Mode Analysis Addendum for the Ripogenus Project under P-2572, Accession Number 20211229-5198, especially the addendum.



We believe that this filing bears on the study requests for the relicensing of the Ripogenus Project and have cross-filed this letter to docket P-2572-133.

Dear Ms. Maloney and Mr. Dorman,

The attached FERC correspondence encouraged Brookfield to:

> work with Trout Unlimited, the resource agencies, and Commission staff to develop a proposal to address strandings and include it in the final license application you file by September 30, 2024.

We had expected this to be addressed in the Ripogenus - Penobscot Mills Revised Study Plan (RSP) that Brookfield recently published. Although the TU report of strandings that the attached FERC letter addresses appears in the RSP as part of Appendix Q beginning on page 315, we do not see strandings addressed by any of the studies proposed in the RSP.

We have not heard from you concerning this issue and ask that you schedule and conduct a teleconference to discuss this by Tuesday, April 5 - before the RSP Comment due date of April 7, 2022.

Thank you for your attention to this matter.

Sincerely,

Stephen G. Heinz
Maine TU Council FERC Coordinator
207 781-4762

**Subject:** RE: Ripogenus Strandings
**Date:** March 31, 2022 at 9:38 AM
**To:** Stephen Heinz heinz@maine.rr.com

RD

Steve,

Thanks for reaching out. As you note, we did not propose a standing study as part of the Revised Study Plan (RSP), filed March 23, 2022. I apologize that our response to your study request is a bit hard to find in the RSP, but it's addressed on page 30 of Appendix R ("Comment and Response Matrix") of the RSP, which then refers back to Section 5.5, "Ramping Study to Determine Appropriate Rate of Flow Change below McKay StaNon."

Our rationale for not adopting the stranding study is the same as the ramping study: we believe that information collected and reported from other proposed studies, such as the Historical Operations Data Assessment Study, will provide information on how the Ripogenus Project has been operated, including flows provided by McKay StaNon.

Thanks again, and we look forward to reading TU's comments on the RSP.

Best,

Randy

PO Box 167
Neshkoro, WI 54960-0167

**Reference: Request for Studies and Additional Information**

Dear Mr. Gates:

After reviewing the Mongaup River Project's Pre-Application Document (PAD), the transcripts of the scoping meetings held June 22, 2017, and participating in a project environmental site review on June 21, 2017, we have determined that additional information is needed to adequately assess potential project effects on environmental resources. We have 11 study requests (enclosed in Schedule A) for aquatic, fisheries, terrestrial, recreational, and cultural resources. We also have additional information needs (enclosed in Schedule B). Please provide the requested additional information in your proposed study plan, which must be filed by September 12, 2017.

Please include in your proposed study plan a master schedule that includes the estimated start and completion date of all field studies, when progress reports will be filed, who will receive the reports and in what format, and the filing date of the initial study report. All studies, including fieldwork, should be initiated and completed during the first study season (unless a second study season is necessary), and the study reports should be filed as a complete package. If, based on the study results, you are likely to

propose any plans for measures to address project effects, drafts of those plans should be filed with your Preliminary Licensing Proposal (or draft license application).

Please note that we may request additional studies or information at a later time, including upon receipt and review of scoping comments/study requests, due July 29, 2017, and your proposed study plan.

If you have any questions, please contact Quinn Emmering at (202) 502-6382, or via e-mail at quinn.emmering@ferc.gov.

Sincerely,

Timothy Konnert, Chief
West Branch
Division of Hydropower Licensing

Enclosures: Schedule A – Study Requests
Schedule B – Additional Information

Public Files

## Schedule A

## Study Requests

After reviewing the information in the Pre-Application Document (PAD), we have identified information that is needed to assess project effects. As required by section 5.9 of the Commission's regulations, we have addressed the seven study request criteria in the study requests that follow.

### Study Request #1 – Reservoir Water Level Fluctuation / Operations Model

Goals and Objectives

§5.9(b)(1) – *Describe the goals and objectives of each study proposal and the information to be obtained.*

The goal of this study is to develop an operations model that may be used to predict reservoir elevations for each of the Mongaup River project reservoirs under various operation constraints (e.g., minimum flow, reservoir level, etc.). The operations model should support an assessment of potential project effects on aquatic, terrestrial, recreation and land use, and aesthetic resources that may result from proposed or recommended project operational scenarios. Specifically, for each project reservoir, the model should be able use historic inflows to predict reservoir outflow, reservoir elevations and surface areas, and corresponding project generation at an appropriate time-step.

§5.9(b)(2) – *If applicable, explain the relevant resource management goals of the agencies or Indian tribes with jurisdiction over the resource to be studied.*

Not applicable.

§5.9(b)(3) – *If the requester is not a resource agency, explain any relevant public interest considerations in regard to the proposed study.*

The Federal Energy Regulatory Commission (Commission) must decide whether to issue new licenses to Eagle Creek Hydro for the projects. Sections 4(e) and 10(a) of the Federal Power Act require the Commission to give equal consideration to all uses of the waterway on which a project is located, and what conditions should be placed on any license that may be issued. In making its license decision, the Commission must equally consider the environmental, recreational, fish and wildlife, and other non-developmental values of the project, as well as power and developmental values. Any license issued must be best adapted to a comprehensive plan for improving or developing a waterway or waterways for all beneficial public uses.

Project operations affect reservoir elevations on a seasonal, weekly, daily, and potentially hourly basis. Therefore, project operations may affect several environmental resources. Understanding the effect of proposed and recommended project operations on generation and reservoir water levels, storage, and surface area, is essential to understand how the Mongaup River projects' operation affects these resources and, therefore, relevant to the Commission's public interest determination.

Background and Existing Information

§5.9(b)(4) – *Describe existing information concerning the subject of the study proposal, and the need for additional information*

The PAD provided general information about the magnitude of the licensed limits for water level fluctuation in the projects reservoirs and provided information on the hydrology of the Mongaup River, and hydraulic capacities of the projects and the proposed operations.

While this information is available, it is insufficient to fully inform an analysis of how proposed and potential project operations may affect generation and the environmental resources discussed above.

Project Nexus

§5.9(b)(5) – *Explain any nexus between project operations and effects (direct, indirect, and/or cumulative) on the resource to be studied, and how the study results would inform the development of license requirements.*

Project operations have the potential to affect reservoir elevations for each of the five reservoirs associated with the Mongaup River projects on a seasonal, weekly, daily, and even hourly basis. The requested operations model should provide information on reservoir water surface area, elevations, and fluctuation rates and support an assessment of potential project effects on aquatic, terrestrial, recreation and land use, and aesthetic resources associated with the reservoirs and that may result from proposed and/or recommended project operational scenarios. This information will inform the development of potential license conditions that consider the non-developmental values of the project, as well as their power and developmental values.

Proposed Methodology

§5.8(b)(6) – *Explain how any proposed study methodology (including any preferred data*

*collection and analysis techniques, or objectively quantified information, and a schedule including appropriate field season(s) and the duration) is consistent with generally accepted practice in the scientific community or, as appropriate, considers relevant tribal values and knowledge.*

Eagle Creek should develop, calibrate, and validate an operations model that integrates each of the three Mongaup River projects and supports the evaluation of proposed and potential recommendations for the project operations, at an hourly (or better) time-step and under various reservoir inflow and outflow conditions. The operations model should be capable of predicting reservoir elevations, surface areas, available storage, and generation that would result from various operational scenarios.

Level of Effort and Cost

§5.9(b)(7) – *Describe considerations of level of effort and cost, as applicable, and why any proposed alternative studies would not be sufficient to meet the stated information needs.*

The estimated cost of the study is approximately $150,000. Eagle Creek did not propose an alternative study.

**Study Request #2 – Aquatic Habitat Mapping of the Projects' Reservoirs**

Goals and Objectives

§5.9(b)(1) – *Describe the goals and objectives of each study proposal and the information to be obtained.*

The goal of this study is to map the aquatic habitat within each of the five reservoirs associated with the Mongaup River projects, evaluate the types of aquatic habitats that occur, and identify any potential effects project operations may have on this habitat.

Specifically, the objectives of the study are to:

1. Survey and map the aquatic habitat types distributed within the reservoirs, from the upper extent of each impoundment to the associated dam.

2. Describe the potential influences of the projects' operations on aquatic habitats within the impoundments.

§5.9(b)(2) – *If applicable, explain the relevant resource management goals of the agencies or Indian tribes with jurisdiction over the resource to be studied.*

Not applicable.

§5.9(b)(3) – *If the requester is not a resource agency, explain any relevant public interest considerations in regard to the proposed study.*

The Federal Energy Regulatory Commission must decide whether to issue new licenses to Eagle Creek Hydro for the projects. Sections 4(e) and 10(a) of the Federal Power Act require the Commission to give equal consideration to all uses of the waterway on which a project is located, and what conditions should be placed on any license that may be issued. In making its license decision, the Commission must equally consider the environmental, recreational, fish and wildlife, and other non-developmental values of the projects, as well as power and developmental values. Any license issued must be best adapted to a comprehensive plan for improving or developing a waterway or waterways for all beneficial public uses.

Aquatic habitats in the projects' reservoirs support an aquatic ecosystem that provides public opportunities, including sport fisheries. This study would provide information needed to determine the effects of project operations on this resource relevant to the Commission's public interest determination.

Background and Existing Information

§5.9(b)(4) – *Describe existing information concerning the subject of the study proposal, and the need for additional information*

Upon review of Eagle Creek's PAD, we find aquatic habitat data for the projects' reservoirs to be very limited. Eagle Creek generally implies that there is a sufficient amount of existing information to support the licensing process, including information on the aquatic habitat resulting from study and/or monitoring in support of the current license. However, the PAD did not include sufficiently detailed information to allow us to determine if the information is adequate to support the Commission's licensing process. As such, additional aquatic habitat information, including the mapped locations of aquatic habitats within each of the projects' reservoirs is needed to evaluate the projects effects on aquatic resources.

Project Nexus

§5.9(b)(5) – *Explain any nexus between project operations and effects (direct, indirect, and/or cumulative) on the resource to be studied, and how the study results would inform the development of license requirements.*

Currently, water levels in the projects' reservoirs fluctuate on a seasonal, weekly, daily, and even hourly basis due to the projects' load-following peaking operations. As a result, any aquatic habitat exposed under low water levels may be adversely affected and/or inhibit the utilization of aquatic habitats by aquatic species during various life stages. These events may also cause fish or other aquatic species (e.g., mussels and macroinvertebrates) stranding and associated mortality.

This requested study would help establish a baseline condition and the health of the aquatic habitat within the projects' reservoirs and assist in forming the basis for inclusion of potential license articles to protect the aquatic resources.

Proposed Methodology

§5.8(b)(6) – *Explain how any proposed study methodology (including any preferred data collection and analysis techniques, or objectively quantified information, and a schedule including appropriate field season(s) and the duration) is consistent with generally accepted practice in the scientific community or, as appropriate, considers relevant tribal values and knowledge.*

Using generally accepted practices in the scientific community:

1. Conduct field surveys of aquatic habitat during full-pool from the head of each of the projects' reservoirs to the associated dam.

2. Categorize habitat survey information per accepted practices in the scientific community (e.g., habitat type, substrate type, depths, etc.) and plot on aerial maps. Also record in-situ water quality conditions (temperature, dissolved oxygen (DO), pH, conductivity) and the presence of invasive aquatic vegetation (species and location).

3. Prepare a report that includes a summary of the data collected. Include in the report, aerial habitat maps that demarcate proposed minimum and maximum reservoir elevations, habitat descriptions, project operations and reservoir elevations and surface areas during the surveys, effects of

proposed project operations on the aquatic habitat(s), and in-situ water quality data. Include all data used to develop the report in an appendix.

Level of Effort and Cost

§5.9(b)(7) – *Describe considerations of level of effort and cost, as applicable, and why any proposed alternative studies would not be sufficient to meet the stated information needs.*

The estimated cost of this work is approximately $100,000 and may be completed within one study season. It is anticipated that two technicians and a biologist would spend about 40 hours in each reservoir to conduct field work. Report preparation would require about a month of a biologist's and/or GIS specialist's time to complete.

We recognize, however, that if more detailed information exists on aquatic habitat in the project reservoirs than what was provided in the PAD, and we determine it to be sufficient to inform our environmental analysis, this requested study should not be necessary.

**Study Request #3 – Baseline Fisheries Population Study**

Goals and Objectives

§5.9(b)(1) – *Describe the goals and objectives of each study proposal and the information to be obtained.*

The goal of this study is to gather baseline fisheries data throughout the projects' area. These data are needed to identify the fish species that occur in the projects' impoundments, tailwaters, downstream riverine corridors, and bypassed reaches as well as to evaluate any potential project effects. Specifically, the objectives of the study are to:

1. Determine the relative abundance and distribution of fish species within the project impoundments, tailwaters, riverine corridors, and bypass reaches within the projects' area.

2. Describe the distribution of fish species within the aquatic habitats and compare and contrast current data with historic survey data.

§5.9(b)(2) – *If applicable, explain the relevant resource management goals of the agencies or Indian tribes with jurisdiction over the resource to be studied.*

Not applicable.

§5.9(b)(3) – *If the requester is not a resource agency, explain any relevant public interest considerations in regard to the proposed study.*

The Federal Energy Regulatory Commission must decide whether to issue new licenses to Eagle Creek Hydro for the projects. Sections 4(e) and 10(a) of the Federal Power Act require the Commission to give equal consideration to all uses of the waterway on which a project is located, and what conditions should be placed on any license that may be issued. In making its license decision, the Commission must equally consider the environmental, recreational, fish and wildlife, and other non-developmental values of the projects, as well as power and developmental values. Any license issued must be best adapted to a comprehensive plan for improving or developing a waterway or waterways for all beneficial public uses.

Fish populations in the Mongaup River support a sport fishery. The effect of project operation on this resource is relevant to the Commission's public interest determination.

Background and Existing Information

§5.9(b)(4) – *Describe existing information concerning the subject of the study proposal, and the need for additional information.*

A review of the PAD, revealed that the New York State Department of Environmental Conservation (NYSDEC) conducted surveys of fish populations for portions of the project area prior to 1980 and in 1987 the prior licensee conducted fish surveys in support of its license application. While this information is existing, project operations, particularly minimum instream flow requirements, were changed when the current license was issued and it appears that no new fisheries data has been collected since those project operational changes occurred, as a result, fisheries population data are needed to evaluate the projects' effects on this resource.

Project Nexus

§5.9(b)(5) – *Explain any nexus between project operations and effects (direct, indirect, and/or cumulative) on the resource to be studied, and how the study results would inform the development of license requirements.*

Potential project effects on fishery resources may include fish entrainment through the generating units, minimum instream flows, and peaking flow operations. Information on the abundance and distribution of the existing fish community would help to identify whether adverse effects are occurring and/or determine whether the current license conditions are protective of the resource as intended.

The applicant is proposing to continue providing the existing minimum flows. Flow releases from the projects have the potential to affect the suitability of aquatic habitat in these reaches, and in turn fishery resources. This requested study would help establish the current baseline condition on the health of the fishery in the projects' area of the Mongaup River basin under the current projects' operation. These data would also assist in informing potential license articles to protect fishery resources in the Mongaup River.

Proposed Methodology

§5.8(b)(6) – *Explain how any proposed study methodology (including any preferred data collection and analysis techniques, or objectively quantified information, and a schedule including appropriate field season(s) and the duration) is consistent with generally accepted practice in the scientific community or, as appropriate, considers relevant tribal values and knowledge.*

Using generally accepted practices in the scientific community:

1. Conduct electrofishing surveys in each of the project impoundments, tailwaters, and downstream riverine corridors, including boat or backpack electrofishing within the bypassed reaches. Conduct sampling during late-summer or fall in order to observe annual juvenile production (juvenile fish would be large enough to collect). Establish sampling locations that represent the full extent and types of habitat in the study area.

2. Separately target upstream and downstream migrating American eels for sampling using generally accepted methods, such as electrofishing, trap/fyke netting, eel pots, etc. to provide data on the abundance of

American eels at various life stages, and where they tend to congregate. Conduct the study in late spring/early summer to target upstream migrating juvenile eels (i.e., elvers and yellow eels), and during the fall to target downstream migrating adults eels (i.e. silver eels).

3. Identify to species and count all collected fish while weighing and measuring only a subsample. Measure eye diameters of captured American eels for use in the evaluating silver eels phase. Identify and record the habitat type and substrate of each sampling location, and record in-situ water quality conditions (temperature, DO, pH, conductivity).

4. Prepare a report that includes a summary of the data from the above studies. Include tabular summaries of fish species collected by station, plus data on lengths, weights, condition factors, and in-situ habitat conditions. Also include specific information relating to American eel population characteristics, such as areas at the base of the dams where elvers congregate, and the abundance of potential downstream migrating silver eels. Include all data used to develop the report (including date and time of collection) within an appendix to the report.

Level of Effort and Cost

§5.9(b)(7) – *Describe considerations of level of effort and cost, as applicable, and why any proposed alternative studies would not be sufficient to meet the stated information needs.*

The estimated cost of this work is approximately $100,000 and may be completed within one study season. It is anticipated that three technicians and a biologist would spend about 160 hours conducting field work for each project. Report preparation would require about 60 hours by a biologist. Eagle Creek did not propose an alternative study.

**Study Request #4 – Stream Reach Water Quality Study**

Goals and Objectives

§5.9(b)(1) – *Describe the goals and objectives of each study proposal and the information to be obtained.*

The goal of this study is to monitor and evaluate water quality within area streams affected by project operations to support an evaluation of the existing minimum instream flow requirements to meet state water quality standards.

Specifically, the study objective is to monitor water quality (e.g., dissolved Oxygen and temperature) on area stream reaches where current water quality data is limited or non-existent.

§5.9(b)(2) – *If applicable, explain the relevant resource management goals of the agencies or Indian tribes with jurisdiction over the resource to be studied.*

Not applicable.

§5.9(b)(3) – *If the requester is not a resource agency, explain any relevant public interest considerations in regard to the proposed study.*

The Federal Energy Regulatory Commission must decide whether to issue new licenses to Eagle Creek Hydro for the projects. Sections 4(e) and 10(a) of the Federal Power Act require the Commission to give equal consideration to all uses of the waterway on which a project is located, and what conditions should be placed on any license that may be issued. In making its license decision, the Commission must equally consider the environmental, recreational, fish and wildlife, and other non-developmental values of the projects, as well as power and developmental values. Any license issued must be best adapted to a comprehensive plan for improving or developing a waterway or waterways for all beneficial public uses.

Water quality in project affected reaches of area streams support an aquatic ecosystem that provides public opportunities, including sport fisheries. Ensuring that the effect of project operations pertaining to this resource is considered in a reasoned way is relevant to the Commission's public interest determination.

Background and Existing Information

§5.9(b)(4) – *Describe existing information concerning the subject of the study proposal, and the need for additional information*

Pursuant to its existing license, Eagle Creek has monitored summer and fall dissolved Oxygen and water temperature downstream of the Swinging Bridge, Mongaup Falls, and Rio Powerhouses since 2011 and the PAD summarizes these monitoring results. In addition, a U.S. Geological Survey (USGS) gage station (Station No.

01433500) has collected water quality data immediately downstream of the Rio Project's tailrace on the Mongaup River since October 1, 2013. However, there are several reaches of area streams that are affected by project operations where water quality monitoring does not appear to have been conducted and no water quality data has been presented. These reaches include:

- Black Lake Creek between Toronto Reservoir and Cliff Lake,
- Black Lake Creek between Cliff Lake Reservoir and its confluence with the Mongaup River,
- the Mongaup River between the Swinging Bridge Powerhouse No. 2 and the Mongaup Falls Project reservoir,[1]
- the Mongaup Falls Project's bypassed reach on the Mongaup River, and
- the Rio Project's bypassed reach on the Mongaup River.

Project Nexus

§5.9(b)(5) – *Explain any nexus between project operations and effects (direct, indirect, and/or cumulative) on the resource to be studied, and how the study results would inform the development of license requirements.*

The existing license requires Eagle Creek to release minimum flows from the project's reservoirs to the five area stream reaches mentioned above. The presence of upstream project reservoirs and the projects' operations alter the stream flow which subsequently affects water quality.

This requested study would help establish the baseline water quality condition within these five affected area stream reaches and aid in determining the adequacy of the minimum instream flow release for protecting water quality and assist in forming the basis for inclusion of potential license articles to protect water quality and aquatic resources therein.

Proposed Methodology

§5.8(b)(6) – *Explain how any proposed study methodology (including any preferred data collection and analysis techniques, or objectively quantified information, and a schedule including appropriate field season(s) and the duration) is consistent with generally*

[1] We recognize that Eagle Creek monitors the water quality 0.3 miles downstream of the Swinging Bridge Powerhouse No. 2 tailrace.

*accepted practice in the scientific community or, as appropriate, considers relevant tribal values and knowledge.*

1. Using generally accepted practices in the scientific community monitor water quality (DO and water temperature) from June 1 through September 30 on a fifteen minute interval at the following locations:

    - Black Lake Creek at the discharge of the Toronto Reservoir,
    - Immediately upstream of the mouth of Black Lake Creek at Cliff Lake,
    - Black Lake Creek at the discharge of Cliff Lake,
    - Black Lake Creek immediately upstream of its confluence with the Mongaup River,
    - Mongaup River immediately upstream of the Mongaup Falls Project reservoir,
    - Mongaup River immediately downstream of the Mongaup Falls Project's minimum flow outlet structure discharge (upper extent of the bypass reach),
    - Mongaup River immediately upstream of the Mongaup Falls tailrace (lower extent of the bypassed reach),
    - Mongaup River immediately downstream of the Rio minimum flow powerhouse (upper extent of the bypassed reach), and
    - Mongaup River immediately upstream of the Rio Project's tailrace (lower extent of the bypassed reach).

2. Document and record stream flows within each project affected stream reach during the study period on the same 15 minute interval that water quality data is collected.

3. Record ambient air temperature at each water quality monitoring location during the study period.

4. Prepare a comprehensive water quality study report for each of the projects' affected stream reaches that incorporates all existing water quality data collected pursuant to the current license and USGS gage Station No. 01433500, the new water quality data collected pursuant to this study request, and consider the influence of ambient air temperature and stream flows on water quality within the project affected stream reaches.

Level of Effort and Cost

§5.9(b)(7) – *Describe considerations of level of effort and cost, as applicable, and why any proposed alternative studies would not be sufficient to meet the stated information needs.*

The estimated cost of this work is approximately $40,000 and may be completed within one study season. It is anticipated that it will take two technicians, eight days to deploy and retrieve the monitoring equipment (including travel and staging) and about 80 to 100 hours for oversight and report preparation by a senior biologist.

**Study Request #5 – Reservoir Water Quality Study**

Goals and Objectives

§5.9(b)(1) – *Describe the goals and objectives of each study proposal and the information to be obtained.*

The goals and objectives of this study are to monitor baseline water quality conditions within the projects' reservoirs to support an evaluation of the existing condition and potential effects on aquatic habitats within project reservoirs and determine if reservoir water quality meets state water quality standards.

§5.9(b)(2) – *If applicable, explain the relevant resource management goals of the agencies or Indian tribes with jurisdiction over the resource to be studied.*

Not applicable.

§5.9(b)(3) – *If the requester is not a resource agency, explain any relevant public interest considerations in regard to the proposed study.*

The Federal Energy Regulatory Commission must decide whether to issue new licenses to Eagle Creek Hydro for the projects. Sections 4(e) and 10(a) of the Federal Power Act require the Commission to give equal consideration to all uses of the waterway on which a project is located, and what conditions should be placed on any license that may be issued. In making its license decision, the Commission must equally consider the environmental, recreational, fish and wildlife, and other non-developmental values of the projects, as well as power and developmental values. Any license issued must be best adapted to a comprehensive plan for improving or developing a waterway or waterways for all beneficial public uses.

Water quality in the projects' reservoirs support aquatic habitats and public recreational opportunities, such as swimming, boating, and fishing. Therefore, evaluating the effect of the projects' operations on reservoir water quality is relevant to the Commission's public interest determination.

Background and Existing Information

§5.9(b)(4) – *Describe existing information concerning the subject of the study proposal, and the need for additional information*

The PAD provide very little information about the water quality within the projects' reservoirs. Swinging Bridge Reservoir was assessed and included in the NYSDEC 2002 *Water Body Inventory / Priority Waterbodies List* (NYSDEC 2002) as an impaired water body.[2] That assessment noted that hydrologic impacts associated with hydropower generation may have been an issue affecting the reservoir's water quality and influenced its inclusion on the list. However, Swinging Bridge Reservoir was not included NYSDEC's proposed final Section 303(d) list in 2016 (NYSDEC 2016). The PAD also acknowledges that during the summer, the hypolimnion in Toronto and Swinging Bridge reservoirs, become anoxic; however, the source of this information appears to be limited and possibly anecdotal. Similarly, the PAD notes that Rio reservoirs hypolimnion becomes anoxic when thermally stratified and cites Orange and Rockland Utilities 1988 license application for the project (Orange and Rockland 1998). The PAD also notes that the Mongaup Falls reservoir hypolimnion does remain oxygenated during the summer months and contributes this to project operations and subsequent turbulence within the reservoir that disrupt the development of a thermocline; however, no citation or supporting data is provided in the PAD.

Project Nexus

§5.9(b)(5) – *Explain any nexus between project operations and effects (direct, indirect, and/or cumulative) on the resource to be studied, and how the study results would inform the development of license requirements.*

Water quality in the projects' reservoirs may affect aquatic habitats and influence public recreation opportunities within the reservoirs. As mentioned above and demonstrated in the Mongaup Falls reservoir, project operational regimes can influence

[2] Toronto, Cliff Lake, Mongaup Falls, and Rio reservoirs were not assessed in the 2002 inventory.

the water quality within a reservoir. Additionally, water discharged from project reservoirs may affect aquatic habitats and biota within the receiving stream reaches. Understanding the existing water quality conditions within the projects' reservoirs is necessary to inform the need for, and the development of, potential license conditions to protect water quality within the reservoirs and downstream riverine reaches for aquatic habitats and biota and recreational opportunities.

Proposed Methodology

§5.8(b)(6) – *Explain how any proposed study methodology (including any preferred data collection and analysis techniques, or objectively quantified information, and a schedule including appropriate field season(s) and the duration) is consistent with generally accepted practice in the scientific community or, as appropriate, considers relevant tribal values and knowledge.*

1. Using generally accepted practices in the scientific community monitor water quality (e.g., water temperature and DO) within each of the projects' reservoirs from ice-off in the spring until ice-on in the winter. Water quality data must be monitored at appropriate locations within each reservoir and at 1-meter increments in depth from the reservoir surface to its bottom. An additional monitoring location must be established at the project intakes (depth and location) within each reservoirs. Data collected should be sufficiently robust to evaluate and consider what, if any, short- and/or long-term (seasonal) influences project operations may have on reservoir water quality (e.g., thermocline depth, water temperature, etc.).

2. Prepare a comprehensive water quality study report for each of the projects' reservoirs that incorporates the water quality data collected pursuant to this study request and as appropriate, the in-situ water quality data collected pursuant to the aquatic habitat mapping study discussed above.

Level of Effort and Cost

§5.9(b)(7) – *Describe considerations of level of effort and cost, as applicable, and why any proposed alternative studies would not be sufficient to meet the stated information needs.*

The estimated cost of this work is approximately $110,000 and may be completed within one study season. It is anticipated that it will take two technicians, 28 days to

deploy, maintain, and retrieve the monitoring equipment (including travel and staging) and about 80-100 hours for oversight and report preparation by a senior biologist.

**Study Request #6 – Special-status Wildlife Species and Habitat Assessment**

Goals and Objectives

§5.9 (b)(1) – *Describe the goals and objectives of each study proposal and the information to be obtained.*

The goal of this study is to develop additional information to supplement the existing information necessary to address the potential effects of project operations and maintenance (O&M), land management activities, and recreation use on the presence of special-status wildlife species[3] and their habitat. The specific information to be obtained is the type, abundance, and general distribution of special-status wildlife species and their habitat within the project area, required to assess the potential effects of the project on these species.

§5.9(b)(2) – *If applicable, explain the relevant resource management goals of the agencies or Indian tribes with jurisdiction over the resource to be studied.*

Not applicable.

§5.9(b)(3) – *If the requester is not a resource agency, explain any relevant public interest considerations in regard to the proposed study.*

The Federal Energy Regulatory Commission must decide whether to issue new licenses to Eagle Creek Hydro for the projects. Sections 4(e) and 10(a) of the Federal Power Act require the Commission to give equal consideration to all uses of the waterway on which a project is located, and what conditions should be placed on any license that may be issued. In making its license decision, the Commission must equally consider the environmental, recreational, fish and wildlife, and other non-developmental values of the project, as well as power and developmental values. Any license issued must be best adapted to a comprehensive plan for improving or developing a waterway or waterways for all beneficial public uses.

[3] Special-status wildlife species include federally listed threatened and endangered species, proposed species, candidate species, and species of concern; state protected species; and species of conservation concern.

Special-status species are of particular interest because of their rarity and ecological functions. Ensuring that environmental measures pertaining to these resources are considered in a reasoned way is relevant to the Commission's public interest determination. Additionally, this information may be needed to ensure compliance with the Endangered Species Act.

Background and Existing Information

§5.9(b)(4) – *Describe existing information concerning the subject of the study proposal, and the need for additional information.*

Special-status wildlife species, such as federally listed northern long-eared bat, Indiana bat, and bog turtle as well as several state-listed species are identified in the PAD as potentially occurring in the project area. NYSDEC has indicated that bald eagles use all five reservoirs associated with the projects in the winter, but no information was provided regarding potential breeding pairs using the projects. NYSDEC also indicated that state-listed peregrine falcon nests and timber rattlesnake are found in the project area. NYSDEC conducted surveys for the New York State Breeding Bird Atlas from 2000 to 2005 which provided a list of potential bird species in the project area including species of conservation concern such as the wood thrush, Canada warbler, and bobolink. There are, however, no comprehensive surveys to identify the abundance, timing, activities, and general distribution of special-status wildlife species or their habitats within the project area.

This information will inform the development of potential license conditions that consider the non-developmental values of the project, as well as their power and developmental values. Additionally, this information may be needed to ensure compliance with the Endangered Species Act.

Project Nexus

§5.9(b)(5) – *Explain any nexus between project operations and effects (direct, indirect, and/or cumulative) on the resource to be studied, and how the study results would inform the development of license requirements.*

Project O&M as well as recreation use associated with the project, have the potential to affect special-status wildlife species and their habitat in the project area. This study will assist in identifying special-status wildlife species within the project area and the need for measures to reduce or eliminate effects.

Proposed Methodology

§5.8(b)(6) – *Explain how any proposed study methodology (including any preferred data collection and analysis techniques, or objectively quantified information, and a schedule including appropriate field season(s) and the duration) is consistent with generally accepted practice in the scientific community or, as appropriate, considers relevant tribal values and knowledge.*

Office Review

Prior to field surveys, the candidate list of special-status wildlife species should be confirmed and developed in consultation with the U.S. Fish and Wildlife Service (FWS) and NYSDEC and include all special-status species currently identified in the PAD. Consultation with resource agencies should also determine recommended survey protocols for each species. Habitat maps and/or aerial photographs should be used to determine habitats that have the potential to support special-status wildlife species for field surveys.

Field Surveys

Field surveys for special-status wildlife in appropriate habitats should be conducted by individuals with experience conducting wildlife field surveys; knowledge of animal taxonomy and animal ecology and classification; familiarity with the wildlife of the area; and experience with analyzing impacts of a project on native wildlife species.

Field surveys should cover the entire area directly and indirectly affected by the project during the appropriate seasons. Multiple surveys should be conducted to locate all potential special-status wildlife species and should also assess seasonal habitat use when relevant (e.g. bat maternity sites and winter hibernacula). Survey protocols should follow accepted and agency recommended wildlife species survey guidelines and protocols.[4] Some project features may also provide suitable roosting and hibernating habitat for special-status bat species and therefore should also be surveyed. The abundance, distribution, and habitat use (including raptor nest sites) of all special-status species should be documented and the locations of all special-status species and their potential habitat should be indicated on maps showing the relationship to project features.

A report should be prepared that includes the results (including photo documentation) of the surveys and mapping efforts and identifies, describes, and assesses

[4] Available through the FWS's IPaC system at https://ecos.fws.gov/ipac/.

the extent to which project-related actions and activities may affect special-status wildlife species and their habitat. The report will include the issues addressed, objectives, study area, methods, analysis, results, discussion, and conclusions. The report should also include documentation of consultation with relevant resource agencies.

Level of Effort and Cost

§5.9(b)(7) – *Describe considerations of level of effort and cost, as applicable, and why any proposed alternative studies would not be sufficient to meet the stated information needs.*

The estimated cost of this work is approximately $180,000, based on one study season and the amount of habitat that has the potential to support special-status wildlife species. It's anticipated that a technician and a biologist would spend one week of desktop review and planning in preparation for field work. One biologist and two technicians would spend about 300 hours conducting field work. Report preparation is estimated at six weeks of a biologist's and technician's time to complete.

**Study Request #7 – Special-status Plant Species and Noxious Weed Assessment**

Goals and Objectives

§5.9 (b)(1) – *Describe the goals and objectives of each study proposal and the information to be obtained.*

The goal of this study is to develop additional information to supplement the existing information necessary to address the potential effects of project O&M and recreation use on the presence of special-status plant species[5] and the presence and potential spread of noxious terrestrial and aquatic weed species.[6] The specific information to be obtained is the type, abundance, and general distribution of special-status and terrestrial and aquatic noxious weed species within the project area, required to assess the potential effect of the project on these species.

[5] Special-status plant species include federally listed threatened and endangered species, proposed species, candidate species, and species of concern; state protected species; and watch list species.

[6] A noxious weed is any plant designated by a federal, state, or county government as injurious to public health, agriculture, recreation, wildlife, or property.

§5.9(b)(2) – *If applicable, explain the relevant resource management goals of the agencies or Indian tribes with jurisdiction over the resource to be studied.*

Not applicable.

§5.9(b)(3) – *If the requester is not a resource agency, explain any relevant public interest considerations in regard to the proposed study.*

The Federal Energy Regulatory Commission must decide whether to issue new licenses to Eagle Creek Hydro for the projects. Sections 4(e) and 10(a) of the Federal Power Act require the Commission to give equal consideration to all uses of the waterway on which a project is located, and what conditions should be placed on any license that may be issued. In making its license decision, the Commission must equally consider the environmental, recreational, fish and wildlife, and other non-developmental values of the project, as well as power and developmental values. Any license issued shall be best adapted to a comprehensive plan for improving or developing a waterway or waterways for all beneficial public uses.

Special-status species are of particular interest because of their rarity and/or ecological functions. Noxious weeds are resources of particular interest because of their potential effects on natural ecosystems. Noxious weeds can degrade wildlife habitats, crowd out beneficial native species, create fire hazards, and result in economic losses. Ensuring that environmental measures pertaining to these resources are considered in a reasoned way is relevant to the Commission's public interest determination.

Background and Existing Information

§5.9(b)(4) – *Describe existing information concerning the subject of the study proposal, and the need for additional information.*

Special-status plant species, such as the federally listed small whorled pogonia as well as state-listed species have been identified in the PAD as potentially occurring in the project area. NYSDEC indicated that state-listed riverbank quillwort, dwarf sand-cherry, and swamp buttercup also occur in the project area. Additionally, a list of potential terrestrial and aquatic noxious weed species was provided in the PAD, however no surveys for noxious weed species have ever been conducted.

Currently, there is very limited information concerning the rare plant and noxious weed species that may be present, their relative abundance, habitat associations, locations, information on the possible effects of project O&M activities and recreation

use on these populations as well as the potential effects of noxious weed species on native plant diversity and habitat quality.

Project Nexus

§5.9(b)(5) – *Explain any nexus between project operations and effects (direct, indirect, and/or cumulative) on the resource to be studied, and how the study results would inform the development of license requirements.*

Project O&M as well as recreation use associated with the project, have the potential to destroy special-status plant species as well as introduce and spread noxious weeds in the project area. This study will assist in identifying special-status plants and noxious weeds within the project area and provide baseline information from which to evaluate project alternatives and/or develop and evaluate specific proposals for protection, mitigation, and enhancement of rare plant populations and their habitats and control of noxious weeds.

Proposed Methodology

§5.8(b)(6) – *Explain how any proposed study methodology (including any preferred data collection and analysis techniques, or objectively quantified information, and a schedule including appropriate field season(s) and the duration) is consistent with generally accepted practice in the scientific community or, as appropriate, considers relevant tribal values and knowledge.*

Office Review

Prior to field surveys, the current list of special-status plants identified in the PAD should be confirmed and developed in consultation with FWS and NYSDEC. Field surveys should examine habitat maps and/or aerial photographs to determine vegetation cover types that have the potential to support special-status plant species.

Field Surveys

Field surveys for special-status plants of appropriate habitats should be conducted by individuals with experience conducting floristic field surveys; knowledge of plant taxonomy and plant community ecology and classification; familiarity with the plants of the area; and experience with analyzing impacts of a project on native plant species. Field surveys should be floristic and cover the entire area affected by the project during the appropriate blooming periods. Multiple surveys should be conducted to locate all

potential special-status species. Two study seasons should be performed to confirm the presence of rare, special-status plant species. The survey protocol will follow accepted special-status plant survey guidelines. The abundance and distribution of all special-status species should be documented and indicated on maps showing the relationship to proposed project features.

Aquatic[7] and noxious weed surveys should map noxious weed occurrence and distribution and be conducted in conjunction with the special-status plant surveys using generally accepted practices in the scientific community. All remaining aquatic habitats not covered in Study Request #2 should also be surveyed for aquatic noxious weed species. The surveys will serve to identify the current extent of weed infestations in a general sense throughout the project area, the species that occur, and the relative abundance of each species.

After completion of the field surveys, prepare a report that includes the results of the surveys and mapping efforts and identifies, describes, and assesses the extent to which project-related actions and activities may affect special-status plants and noxious weeds. The report should include the issues addressed, objectives, study area, methods, analysis, results, project-specific maps with known occurrences of special-status plants and noxious weed species, discussion, and conclusions.

Level of Effort and Cost

§5.9(b)(7) – *Describe considerations of level of effort and cost, as applicable, and why any proposed alternative studies would not be sufficient to meet the stated information needs.*

The estimated cost of this work is approximately $86,000, based on two study seasons and depending upon the amount of habitat that has the potential to support special-status species and noxious weed species. It's anticipated that a technician would spend one week of desktop review and planning in preparation for field work. One biologist and a single technician would spend about 100 hours conducting field work. Report preparation would require about two weeks of a biologist's and technician's time to complete.

[7] Aquatic weed species associated with lacustrine habitats are included in Study Request #2 – Aquatic Habitat Mapping of the Projects' Reservoirs.

**Study Request #8 – Recreation Facility Inventory, Recreation Use and Needs Assessment, and Reservoir Surface Area Assessment**

Goals and Objectives

§5.9(b)(1) – *Describe the goals and objectives of each study proposal and the information to be obtained.*

The goals of the Recreation Facility Inventory, Recreation Use and Needs Assessment, and Reservoir Surface Area Assessment are to: (1) obtain information about the condition of existing recreation facilities and access sites at the projects; and existing recreation use, access, and demand at the projects; (2) conduct an assessment of the need to enhance recreation opportunities and access at the projects; (3) quantify and map the relationship between reservoir surface area and reservoir levels; and (4) develop a Recreation Management Plan for the implementation of any enhancement measures and long-term monitoring of recreation demand and adequacy of facilities at the projects over the terms of new licenses.

§5.9(b)(2) – *If applicable, explain the relevant resource management goals of the agencies or Indian tribes with jurisdiction over the resource to be studied.*

Not applicable.

§5.9(b)(3) – *If the requester is not a resource agency, explain any relevant public interest considerations in regard to the proposed study.*

The Federal Energy Regulatory Commission must decide whether to issue new licenses to Eagle Creek for the projects. Sections 4(e) and 10(a) of the Federal Power Act require the Commission to give equal consideration to all uses of the waterway on which a project is located, and what conditions should be placed on any license that may be issued. In making its license decision, the Commission must equally consider the environmental, recreational, fish and wildlife, and other non-developmental values of the projects, as well as power and developmental values. Any license issued must be best adapted to a comprehensive plan for improving or developing a waterway or waterways for all beneficial public uses.

Recreation has been identified as a project purpose by the Commission. Applicants are encouraged to develop recreation resources in such a matter that is "consistent with the needs of the area to the extent that such development is not inconsistent with the primary purpose of the project" (18 C.F.R. §2.7). Identifying

effects of project operations pertaining to this resource is relevant to the Commission's public interest determination.

Background and Existing Information

§5.9(b)(4) – *Describe existing information concerning the subject of the study proposal, and the need for additional information*

Section 5.8 of the PAD provides a summary of project-related recreation activities and recreation facilities. It also provides a general discussion of recreation demand in the region. However, the PAD provides no project-specific information regarding visitor perceptions of recreation at the projects, nor any information of how project operations may affect the visitor experience. Public recreation access and reservoir levels were two of the primary topics discussed by members of the public during the June 22, 2017, scoping meetings. Furthermore, there is an extensive record of a variety of conflicts associated with public recreation access at the projects. Information on visitor perceptions of the adequacy of public access and facilities, current use, and whether existing access facilities in the area are meeting recreation demand would inform future license conditions related to public access and recreation facilities. Information on reservoir surface area would inform our analysis of the impact of project operations on recreational opportunities at the projects.

Project Nexus

§5.9(b)(5) – *Explain any nexus between project operations and effects (direct, indirect, and/or cumulative) on the resource to be studied, and how the study results would inform the development of license requirements.*

The projects include five reservoirs and one bypassed reach with recreational opportunities. An analysis of existing recreation use and access at the projects would help form the basis for determining the projects' ability to enhance public recreation opportunities. Also, an assessment of the current level of recreation use and how project operation may affect use would provide information necessary to develop a Recreation Management Plan for efficient management of the recreational components of the projects over the terms of new licenses.

Proposed Methodology

§5.8(b)(6) – *Explain how any proposed study methodology (including any preferred data collection and analysis techniques, or objectively quantified information, and a schedule*

*including appropriate field season(s) and the duration) is consistent with generally accepted practice in the scientific community or, as appropriate, considers relevant tribal values and knowledge.*

1. Update existing data on recreation resources adjacent to and within the projects through site assessment and consultation with public and private recreation providers.

2. Update the inventory of informal and formal public and private waterfront recreational sites/facilities within and adjacent to the project boundaries. Identify all informal and formal public and private recreational sites/facilities within the project areas.

3. Develop and implement a site condition evaluation criterion of measurable and manageable indicators for facilities and dispersed recreation area conditions. Site condition assessments should be conducted at all formal and informal publicly accessible recreation sites. Eagle Creek Hydro should also consult with the NYSDEC to evaluate the need of including other NYSDEC recreational developments that serve the projects into the site condition assessment.

4. The use and needs assessment should include all recreation activity types known to occur or potentially occurring at the projects. Specific methods should include visitor observations and on-site visitor intercept surveys at formal and informal public recreation areas at the project reservoirs and riverine areas, including the bypassed reach between the Rio Project minimum flow powerhouse tailrace and the main powerhouse tailrace.

5. Specific methods for each sampling approach in the use and needs assessment:

   - the visitor observations should capture information such as location, date, time, weather, number of vehicles, watercraft (if any), number of recreation users or party size, and recreation activity engaged in; and
   - the visitor survey sampling should be based on a stratified random sample that includes all seasons, various locations, and various times of week and day to enable representative responses from the visitors, while ensuring interview coverage during key times (e.g., holiday and weekend days, shoulder seasons, fishing and hunting seasons).

6. The survey instrument should include items that assess visitor perceptions of crowding, recreational conflict, conflicts between the public and adjacent property owner(s), welcoming public access, adequacy and placement of signage, adequacy of recreation facilities and access to the projects, and effects of project operations and management on recreation and recreation opportunities at the projects (e.g., fluctuating reservoir levels and minimum flow releases).

7. In conjunction with Study #10 requested below, consult with stakeholder groups to develop a whitewater boating-specific addendum to the survey instrument that would rate satisfaction with the current whitewater boating flow release schedule, access facilities, and boating information. The study report should include an assessment of opportunities to modify or enhance the current whitewater flow release schedule, boater access facilities, and/or boating information.

8. Annual recreation use by activity type and season should be quantified to include both formal and informal publicly accessible recreation sites.

9. The needs assessment should also include a future demand estimate from both current use and unmet demand based on guidance from Haas et al. (2007). Specifically, the following information should be integrated to provide an estimate of future recreation demand at the projects: (1) prior and current project use data; (2) state, regional, and national recreation trend data; and (3) population growth data.

10. Quantify the relationship between reservoir surface area and reservoir levels (i.e., reservoir elevation) for the range of operation (i.e., full pool to minimum reservoir level) at each project reservoir. This relationship should also be mapped to visually assess the effects of reservoir levels on reservoir surface area and identify specific areas that may become inaccessible at lower reservoir levels.

11. Identify potential measures to alleviate or reduce any negative effects of project operations, to enhance existing recreation opportunities, and (if appropriate) provide additional public access at the project reservoirs or riverine reaches (potential locations, type of facilities and access, and any associated costs).

12. Using the information from all recreation studies, develop a Recreation Management Plan for the projects. The plan should be included in the license application and should include, at a minimum: (1) description of any proposed protection, mitigation, and enhancement measures, including: location of any proposed facilities and/or access areas (including descriptions and figures depicting the relationship of any proposed facilities to the existing project boundaries), proposed ownership and management of any proposed facilities, associated capital, and O&M costs, and a timeline for implementation; (2) description of operation and management measures associated with project-related recreation access and facilities; and (3) an adaptive plan for future monitoring of recreation use, impacts, and adequacy of project-related facilities to meet demand over the term of the new license.

Level of Effort and Cost

§5.9(b)(7) – *Describe considerations of level of effort and cost, as applicable, and why any proposed alternative studies would not be sufficient to meet the stated information needs.*

The estimated cost of the Recreation Facility Inventory, Recreation Use and Needs Assessment, and Reservoir Surface Area Assessment is $95,000, including study plan development, field data collection, reservoir surface area modeling and mapping, study report preparation, and development of the Recreation Management Plan. One field season should be sufficient to collect the required data and prepare the study report.

**Study Request #9 – Shoreline Management Assessment**

Goals and Objectives

§5.9(b)(1) – *Describe the goals and objectives of each study proposal and the information to be obtained.*

The goals of the Shoreline Management Assessment are to: (1) obtain information on the adequacy and appropriateness of current shoreline management practices, and (2) develop a Shoreline Management Plan in consultation with relevant stakeholders.

§5.9(b)(2) – *If applicable, explain the relevant resource management goals of the agencies or Indian tribes with jurisdiction over the resource to be studied.*

Not applicable.

§5.9(b)(3) – *If the requester is not a resource agency, explain any relevant public interest considerations in regard to the proposed study.*

The Federal Energy Regulatory Commission must decide whether to issue new licenses to Eagle Creek for the projects. Sections 4(e) and 10(a) of the Federal Power Act require the Commission to give equal consideration to all uses of the waterway on which a project is located, and what conditions should be placed on any license that may be issued. In making its license decision, the Commission must equally consider the environmental, recreational, fish and wildlife, and other non-developmental values of the projects, as well as power and developmental values. Any license issued must be best adapted to a comprehensive plan for improving or developing a waterway or waterways for all beneficial public uses.

Recreation has been identified as a project purpose by the Commission. Applicants are encouraged to develop recreation resources in such a matter that is "consistent with the needs of the area to the extent that such development is not inconsistent with the primary purpose of the project" (18 C.F.R. §2.7). Identifying effects of project operations pertaining to this resource is relevant to the Commission's public interest determination.

Background and Existing Information

§5.9(b)(4) – *Describe existing information concerning the subject of the study proposal, and the need for additional information*

The PAD includes only limited information on shoreline management in Sections 5.8.5 and 5.8.9. We note that, although it did not include it in the PAD, Eagle Creek Hydro did file the current "shoreline management guidelines" with the Commission on June 5, 2015. During the June 22, 2017, scoping meetings, several shoreline property owners expressed concerns regarding shoreline management issues and reservoir levels. Additionally, there is an extensive record of complaints related to shoreline management

issues. Therefore, Commission staff needs information on current shoreline management practices in order to determine whether these practices are adequate and appropriate.

Project Nexus

§5.9(b)(5) – *Explain any nexus between project operations and effects (direct, indirect, and/or cumulative) on the resource to be studied, and how the study results would inform the development of license requirements.*

The projects include five reservoirs. Currently, private residential and commercial developments are primarily located on the Toronto and Swinging Bridge reservoirs. Eagle Creek Hydro is directly responsible for shoreline management at the projects. Additionally, project operations directly impact reservoir levels, and reservoir levels affect shoreline management practices. An assessment of current shoreline management practices would provide the information necessary to develop a Shoreline Management Plan that would be implemented over the terms of any new licenses issued for the projects.

Proposed Methodology

§5.8(b)(6) – *Explain how any proposed study methodology (including any preferred data collection and analysis techniques, or objectively quantified information, and a schedule including appropriate field season(s) and the duration) is consistent with generally accepted practice in the scientific community or, as appropriate, considers relevant tribal values and knowledge.*

1. Develop a questionnaire to solicit information from shoreline property owners at each project reservoir about their recreation activity participation, areas visited, perspectives about reservoir levels and current shoreline management practices, perceived conflicts and crowding, and their satisfaction with or desire for recreational opportunities and facilities.

2. The applicant should consult with representatives of the various shoreline property owners on the most effective means of distributing the questionnaire. Regardless of how the questionnaire is distributed (i.e., mail, email, or internet), the applicant should follow the Dillman (2014) tailored design method. This method would help ensure that property owners have ample opportunity to complete the survey and would help increase survey response rates. The applicant should also consult with interested stakeholders, including property owner representatives and the

NYSDEC, and Commission staff in the development of the questionnaire before it conducts the study.

3. Prepare a detailed report of the study results, and use these results in conjunction with the results of the other recreation studies to inform the development of a Shoreline Management Plan. Interested stakeholders should be given the opportunity to comment on the draft plan. The plan should be included in the license application and should include, at a minimum: (1) a detailed description of all rules, regulations, guidelines, and measures associated with non-project use or occupancy of project lands, (2) documentation of consultation with interested stakeholders, (3) an appendix containing stakeholder comments on the draft plan and Eagle Creek Hydro's responses to them, and (4) an adaptive plan for future plan revisions that includes provisions for consultation with relevant stakeholders.

Level of Effort and Cost

§5.9(b)(7) – *Describe considerations of level of effort and cost, as applicable, and why any proposed alternative studies would not be sufficient to meet the stated information needs.*

The estimated cost of the Shoreline Management Assessment is $30,000, including questionnaire development and distribution, study report development, and drafting of a Shoreline Management Plan. This figure could vary depending on how the questionnaire is distributed.

**Study Request #10 – Whitewater Boating Assessment**

Goals and Objectives

§5.9(b)(1) – *Describe the goals and objectives of each study proposal and the information to be obtained.*

The goals and objectives of the Whitewater Boating Assessment are to: (1) evaluate the adequacy and appropriateness of the current whitewater boating opportunities at the projects, including flow releases and access facilities; (2) assess whitewater boating opportunities in the bypassed reach between the Rio Project minimum flow powerhouse tailrace and the main powerhouse tailrace; and (3) identify

potential measures to enhance whitewater boating opportunities at the projects over the terms of new licenses.

§5.9(b)(2) – *If applicable, explain the relevant resource management goals of the agencies or Indian tribes with jurisdiction over the resource to be studied.*

Not applicable.

§5.9(b)(3) – *If the requester is not a resource agency, explain any relevant public interest considerations in regard to the proposed study.*

The Federal Energy Regulatory Commission must decide whether to issue new licenses to Eagle Creek for the projects. Sections 4(e) and 10(a) of the Federal Power Act require the Commission to give equal consideration to all uses of the waterway on which a project is located, and what conditions should be placed on any license that may be issued. In making its license decision, the Commission must equally consider the environmental, recreational, fish and wildlife, and other non-developmental values of the projects, as well as power and developmental values. Any license issued must be best adapted to a comprehensive plan for improving or developing a waterway or waterways for all beneficial public uses.

Recreation has been identified as a project purpose by the Commission. Applicants are encouraged to develop recreation resources in such a matter that is "consistent with the needs of the area to the extent that such development is not inconsistent with the primary purpose of the project" (18 C.F.R. §2.7). Identifying effects of project operations pertaining to this resource is relevant to the Commission's public interest determination.

Background and Existing Information

§5.9(b)(4) – *Describe existing information concerning the subject of the study proposal, and the need for additional information*

The PAD includes only limited information on recreation at the projects, including whitewater boating, in Section 5.8.1. The PAD briefly describes the Rio Project's whitewater boating access facility and references the current whitewater boating flow release schedule, but does not include the study report from the whitewater boating study conducted in the spring of 1990 that is referenced in the current license order.[8]

[8] *See* 59 FERC ¶ 62,035

Furthermore, the PAD does not include any information on the bypassed reach between the Rio Project minimum flow powerhouse tailrace and the main powerhouse tailrace.

Project Nexus

§5.9(b)(5) – *Explain any nexus between project operations and effects (direct, indirect, and/or cumulative) on the resource to be studied, and how the study results would inform the development of license requirements.*

The current license for the Rio Project requires scheduled weekend whitewater flow releases based on a study completed in the spring of 1990. Project operations have a direct impact on whitewater boating below the main powerhouse tailrace because the Rio Project generates power during times of peak demand, which are typically weekdays in the summer. Therefore, an analysis of the current flow release schedule would determine if any changes are necessary, and would inform potential license conditions related to the whitewater flow release schedule. Additionally, project operations divert flows from the Mongaup River below the Rio Project's minimum flow powerhouse that could possibly provide whitewater boating opportunities. An analysis of project operations relative to a range of boatable flows would help inform potential license conditions pertaining to whitewater boating opportunities in the bypassed reach.

Proposed Methodology

§5.8(b)(6) – *Explain how any proposed study methodology (including any preferred data collection and analysis techniques, or objectively quantified information, and a schedule including appropriate field season(s) and the duration) is consistent with generally accepted practice in the scientific community or, as appropriate, considers relevant tribal values and knowledge.*

The Whitewater Boating Assessment will have two primary components:

1. For the current whitewater boating opportunities below the Rio Project's main powerhouse tailrace, in conjunction with the overall recreation study (Study # 8) requested above, evaluate the current flow release schedule, boater access facilities, and boating information provided at the projects. Obtain any available study report or data from the study conducted in 1990. Consult with stakeholder groups and Commission staff to determine if the existing information is adequate. If inadequate, then conduct a whitewater boating study based on accepted practices (i.e. Whittaker et al., 2005).

2. For the bypassed reach, use accepted practices for a whitewater boating study as described in Whittaker et al. (2005). The study should use a sequential three-phased approach.

    - Phase I: Use a desktop analysis to identify access options for the bypassed reach, create a gradient profile, and identify any other flow-related information that may be pertinent to recreation in the bypassed reach.
    - Phase II: Use experienced whitewater boaters to conduct an on-land feasibility assessment by scouting the bypassed reach to examine potential quality and characteristics of boating opportunities, estimate potential flow ranges, identify obvious hazards, and determine whether an on-water controlled flow study is needed to evaluate whitewater recreational opportunities in the bypassed reach.
    - Phase III: If determined to be necessary by Phase II, use an on-water controlled flow evaluation to determine the acceptable minimum and optimal instream flow needed for whitewater boating in the bypassed reach.

Prepare a study report for each phase of the study. The Phase I report should include a description and maps of potential access options to the bypassed reach, and any additional pertinent information identified about flows and recreation in the bypassed reach. The Phase II report should include an assessment of study participants' evaluations for potential quality and characteristics of boating opportunities (e.g. difficulty, type of run, type of craft likely suitable for the run), estimated potential flow ranges, obvious hazards (e.g. woody growth in the river bed), and recommendations for implementing Phase III. The Phase III report (if necessary) should include a description of the whitewater boating attributes of the range of flows examined (e.g. difficulty, unique features, portage requirements), determine the acceptable and optimal flows for the reach, the frequency of availability of the identified flows under current and any proposed project operation modifications, and incorporate relevant results from other studies to identify any competing recreational uses (e.g. fishing) or other resource needs (e.g. aquatic habitat) that may be adversely affected by any scheduled releases.

Level of Effort and Cost

§5.9(b)(7) – *Describe considerations of level of effort and cost, as applicable, and why any proposed alternative studies would not be sufficient to meet the stated information needs.*

Eagle Creek Hydro should develop the detailed study protocol, logistics, and schedule in consultation with interested stakeholders. The estimated cost of the whitewater boating assessment is approximately $45,000, depending upon the adequacy of existing information and the extent of fieldwork conducted.

**Study Request #11 – Cultural Resources**

Goals and Objectives

§5.9(b)(1) – *Describe the goals and objectives of each study proposal and the information to be obtained.*

The goal of this study is to locate cultural resources that are eligible for the National Register of Historic Places (National Register) and may be affected by project O&M (including recreational activities associated with the projects reservoirs) within the FERC project boundary and respective area of potential effects (APE).[9] Such cultural resources would include archaeological sites, project facilities, historic structures, and other places of religious and cultural significance to Indian tribes. The study would determine an APE to locate cultural resources and assess specific project-related effects to any cultural resource determined to be eligible for the National Register. If existing or potential project-related adverse effects are identified on National Register-eligible cultural resources, a historic properties management plan (HPMP) would be crafted to resolve any such adverse effects and made part of any new licenses issued by the Commission.[10]

§5.9(b)(2) – *If applicable, explain the relevant resource management goals of the agencies or Indian tribes with jurisdiction over the resource to be studied.*

[9] This study would comply with all aspects as specified in the implementing regulations (36 CFR Part 800) of section 106 of the National Historic Preservation Act, as amended.

[10] Using the information and findings from the cultural resources study, a draft HPMP would be filed with a draft license application, and a final HPMP with a final license application. Prior to filing the draft and final HPMPs with the draft (or PLP) and final licenses, respectively, the HPMPs would be submitted to the New York SHPO and any involved Indian tribe for review and comment.

The results of the cultural resources study would be reviewed and commented by the New York State Historic Preservation Officer (SHPO) and any involved Indian tribe. The APE (including a description and map) would also need to be approved by the New York SHPO prior to conducting field investigations related to the cultural resources study. Any National Register eligibility recommendations to cultural resources located within the APE would also need to be approved by the New York SHPO. If existing or potential project-related adverse effects are identified on National Register-eligible properties within the project's APE, the Advisory Council on Historic Preservation (Council) must be notified and given an opportunity to comment.[11]

§5.9(b)(3) – *If the requester is not a resource agency, explain any relevant public interest considerations in regard to the proposed study.*

The Commission must decide whether to issue new licenses to Eagle Creek Hydro for the projects. Issuing new licenses by the Commission is considered a federal undertaking, pursuant to section 106 of the National Historic Preservation Act (section 106), and requires the Commission to take into account any existing or potential project-related adverse effects to historic properties (i.e., those cultural resources determined eligible for the National Register).

Background and Existing Information

§5.9(b)(4) – *Describe existing information concerning the subject of the study proposal, and the need for additional information*

The cultural resources section within the PAD (section 5.10) provided an APE for the projects. Section 5.10 also provided a general cultural context about cultural and historic resources in and near the project area and provided a brief summary of archaeological and historic resources within the vicinity of the projects. Section 5.10 also noted the comments from the Bureau of Indian Affairs stating that the projects are located within a historic Delaware tribal area.

Although the PAD highlighted several undetermined National Register-eligible cultural resources in and near the project vicinity, the information provided is

[11] This is usually done by the Commission when they issue a draft programmatic agreement involving a new or original license.

insufficient.[12] For example, the Swinging Bridge Hydroelectric Plant is a project facility and is within the projects' APE, but its National Register eligibility remains undetermined despite the power plant being more than 50 years old, meeting the age criteria for consideration for inclusion in the National Register. There are other project facilities (i.e., other powerhouses, wood stave penstocks, surge tanks, diversion dams, employee housing) within the APE that also meet the 50-year-old age criteria, but are not mentioned in the PAD, nor are they considered for their National Register eligibility. There is also evidence for non-project historic foundations and potentially related archaeological sites that date prior to the Civil War and exist within the projects' APE. Several historic towns dating the 19th century were known to have been inundated by the project reservoirs. Historic roads are also known near the project area, and some may have crossed into the projects' APE. There is also a potential for pre-contact archaeological sites existing within the projects' APE along the former water courses within the Mongaup River Basin which had served as a historic and traditional area for aboriginal groups associated with the Delaware Indians for hundreds of years prior to European contact.

Project Nexus

§5.9(b)(5) – *Explain any nexus between project operations and effects (direct, indirect, and/or cumulative) on the resource to be studied, and how the study results would inform the development of license requirements.*

Project O&M have the potential to adversely affect project facilities, some of which meet the age criteria for National Register eligibility. Fluctuating water levels produced by the projects within the five reservoirs have the potential to adversely affect inundated town sites, above-ground associated historic foundations and archaeological sites, of which there is no existing information on how extensive any of these cultural resources are, or where they may exist. There is also the potential of pre-contact

[12] Note that a 1987 finding from the New York SHPO stating that the projects would have no effect on districts, sites, buildings, structures, objects, or archaeological resources eligible for listing in the National Register was based on the previous relicensing process more than 25 years ago, and does not apply to the new proposed license, which, in turn, constitutes a new undertaking, pursuant to section 106. Methods used in the 1980s to assess cultural resources for project effects and National Register eligibility would not be accepted under current section 106 standards. At present, none of the FERC project boundary for the projects has been systematically inventoried for historic properties and where assessments for project-related effects to such properties has not been conducted.

aboriginal archaeological sites being adversely affected by the reservoirs. Unauthorized activities by relic collectors utilizing designated project recreational areas could have additional adverse effects on archaeological resources along the shoreline of the reservoirs within the APE.

Proposed Methodology

§5.8(b)(6) – *Explain how any proposed study methodology (including any preferred data collection and analysis techniques, or objectively quantified information, and a schedule including appropriate field season(s) and the duration) is consistent with generally accepted practice in the scientific community or, as appropriate, considers relevant tribal values and knowledge.*

The cultural resources study plan should include the following proposed measures and associated tasks:

1. Upon the issuance of the Commission's Study Plan Determination, submit a definition of the projects' APE and associated APE to the New York SHPO for concurrence. Written concurrence from the New York SHPO should be obtained prior to conducting field work associated with this study.

2. Conduct a systematic cultural resources survey and inventory within the projects' APE. This would include a systematic pedestrian survey within all accessible areas of the APE using a crew of qualified professional archaeologists[13] where all cultural resources encountered would be recorded, mapped, and photographed in compliance with standards set forth by the New York SHPO. Such survey methods would reflect Phase 1A and IB archaeological assessment guidelines provided by the New York SHPO. Once archaeological resources are located and determined to be potentially affected by the projects, National Register eligibility of each site would be assessed using Phase II assessments or other appropriate measures agreed to by the New York State SHPO.

3. Conduct a survey of all built environment resources (i.e., above ground structures) that would include all project facilities and non-project facilities

[13] See Secretary of the Interior's standards and guidelines for archeology and historic preservation.

with the APE. Each built environment resource would need to be assessed as either eligible or not eligible for inclusion in the National Register, and such assessments would need to be done by a qualified architectural historian or other similarly qualified professional.[14] Work conducted should meet the New York SHPO recommended standards for historic resources survey, including maps, site records, and photographs. The possibility of establishing a historic district associated with some or all of the project facilities should be considered that would include both contributing and non-contributing elements. Specific project-related effects would also need to be determined on each built environment resource located with the APE.

4. Contact the Delaware Nation and Delaware Tribe to see if they know of any place of religious or cultural significance (i.e., traditional cultural properties, past villages or sites, gathering areas) and allow them to comment on the cultural resources study in draft and final form. If such cultural resources exist within the APE, assess National Register eligibility (if applicable), and potential or existing project-related effects. This element of the study should be conducted by a knowledgeable person with anthropological training when talking and gaining information from the Indian tribes.

5. State in the study plan, that if there are historic properties within the APE that would be potentially affected by the project, that a draft HPMP would be crafted, in consultation with the New York SHPO and involved Indian tribes, and filed with a draft license application (or PLP), and that a final HPMP, first reviewed by the New York SHPO and involved Indian tribes, would be filed with the final license application.[15] The HPMP would provide measures to resolve any existing or potential project-related adverse effects to historic properties.

---

[14] Ibid.

[15] For crafting a HPMP, use the Council and FERC's Guidelines for the Development of Historic Properties Management Plans for FERC Hydroelectric Projects, issued May 20, 2002.

6. Prepare a cultural resources report based on the tasks above, including a detailed section on the cultural history of the project area, previous studies near and within the projects' APE, methodologies used for field surveys for archaeological resources, built environment resources and pertinent information from Indian tribes on places of religious and cultural importance.[16] Include a section that details the consultation history with the New York SHPO, involved Indian tribes, and any other persons or entities who participated or commented on the cultural resources study. Include a section that details the cultural resources located within the projects' APE, which ones were determined eligible or not eligible for the National Register, and which ones are being adversely affected by existing or future project-related activities. This report should be crafted by a qualified cultural resources professional.

Level of Effort and Cost

§5.9(b)(7) – *Describe considerations of level of effort and cost, as applicable, and why any proposed alternative studies would not be sufficient to meet the stated information needs.*

The estimated cost of the study and report preparation is approximately $100,000 and should be completed within one study season. Eagle Creek did not propose an alternative study.

[16] Due to sensitive archaeological information and maps, mark the cultural resources study report as "privileged' and request that the Secretary of Commission place it in our non-public file. Also distribute the same cultural resources study report to the New York SHPO and interested Indian tribes. This should also be done for any HPMP filed with the Commission.

## Schedule B

## Additional Information

### Aquatic Resources

1. The PAD, section 6.3 *Potential Studies*, states that an instream flow study for bypass and river reaches within the basin was completed by Stetson-Harza (1988), and that Lawler et al. completed a study on the effects of the projects on water quality, fish stranding, and streambank scouring (LMS 1999). However, these studies were not provided with the PAD. So that we may determine whether the studies are sufficient to meet our information needs and support a licensing decision please file the referenced studies and include with the proposed study plan.

2. The PAD, section 5.4.1, states that Lawler et al., conducted empirical entrainment studies at the Mongaup Falls, Swinging Bridge, and Rio Projects in 1992 and 1993 (LMS 1994). However, these studies were not provided with the PAD. So that we may determine whether the studies are sufficient to meet our information needs and support a licensing decision please file the referenced studies and include with the proposed study plan.

**RE: Revised Study Plan Comments for the Ripogenus (FERC No. 2572-133) and Penobscot Mills (FERC No. 2458-247) Hydroelectric Projects**

Dear Secretary Bose:

This is the United States Fish and Wildlife Service's (Service) response to the Revised Study Plan (RSP) for the Ripogenus and Penobscot Mills Hydroelectric Projects (collectively referred to as Project or Projects), located on the West Branch of the Penobscot River and Millinocket Stream in Piscataquis and Penobscot Counties, Maine. The RSP was submitted by Great Lakes Hydro America, LLC (GLHA; Applicant) on March 23, 2022.

## COMMENTS

General

GLHA did not incorporate any of the Service's Proposed Study Plan (PSP) comments into the RSP therefore, rather than reiterate our position, the Service respectfully requests that the Federal Energy Regulatory Commission (Commission) approve the studies requested in our October 7, 2021, Pre-Application Document (PAD) comment letter and February 2, 2022, PSP comment letter.[1,2]

Additionally, the Service supports the Extension of Time request submitted by the National Marine Fisheries Service (NMFS), to allow all stakeholders sufficient time to review all ten years of operations data provided by the Applicant in the RSP.[3] All parties to this licensing

[1] Accession No. 20211007-5023
[2] Accession No. 20220222-5270
[3] On October 8, 2021, the Commission issued an Additional Information Request for detailed operations data which was needed to clarify how the Projects are operated on a daily basis. Specifically, the Commission requested GLHA

proceeding should be allowed to have a precise understanding of the Projects modes of operations to identify any potential effects to environmental resources in Project-affected areas. As stated by NMFS, stakeholders will use the additional 60 days to analyze Project outflows and impoundment elevations and provide the Commission with well-informed comments on the RSP which will ultimately benefit the Environmental Assessment (EA) for this relicensing.

Upstream American Eel Passage Assessment Study – Presence, Distribution, and Relative Abundance

In the RSP, the Applicant proposes "…to utilize the eDNA methodology suggested by MDMR to evaluate the current distribution of American eels upstream of the Projects (Appendix D of this RSP)." GLHA states, "This initial step will inform the relative abundance of eels upstream of the Project developments." However, the abundance and distribution of eels is not in question in this licensing proceeding. Based on existing information, including GLHA's PAD for the Projects, we know that the West Branch of the Penobscot River is historic habitat for eels and that they are currently present in the impoundments above each dam. The PAD states, "Juvenile eels have the ability to ascend damp, rough surfaces of dams, resulting in their distribution above dams in the Project areas (Gulf of Maine Council on the Marine Environment [GMCME] 2007). They also inhabit West Branch riverine habitats and have been documented in fish assemblage catches from the 1980s (FERC 1996) and more recently in 2004 (Yoder, et al. 2008)." Therefore, upstream eel passage siting surveys are needed to determine the optimal locations for siting permanent upstream eel passage facilities at each of the six dams as this information does not exist and a presence, distribution, and relative abundance study is not needed.

> **Service recommendation:** The documented presence of eels alone has elicited the Commission to mandate installation of eelways in its Environmental Assessments at other projects in the Service's Northeast region, most recently at the Blackstone (FERC No. 3023-014), Woonsocket Falls (FERC No. 2972-027), and Central Falls (FERC No. 3063-021) Hydroelectric Projects.[4] Therefore, since the presence and distribution of eels is already known in the West Branch, as stated above and in the Applicant's PAD, the Service respectfully requests that the Commission approves the Service's upstream eel passage study as outlined and described in our PAD and PSP letters.

In addition to the above comments, the Service supports the study requests and clarifications submitted to date by NMFS, the PIN, the Department of Marine Resources, MDIFW, Trout Unlimited, Ed Spear, and the other Non-Governmental Organizations (NGO's) participating in this proceeding.

Thank you for this opportunity to comment. Please direct any questions to Julianne Rosset at julianne_rosset@fws.gov.

---

include 10 years of operations data (in excel format) for each dam, and that this information be filed with GLHA's PSP on, or before, November 23, 2021. However, the requested data was not provided by GLHA by the Commission's November 23rd deadline. On March 23, 2022, and concurrent with GLHA's RSP (four months after the Commission's deadline) some of the requested data was filed, leaving only 15 days for stakeholders to review and comment on ten years of data.

The flow study is needed specific to the “dry way” due to its unique hydrologic features. A thorough analysis should be done before all rules and regulations pertaining to the waterway on both environmental and economic impact. Currently residing outside of this area, guaranteed releases would encourage me to travel to this location more frequently if there is reliable access to the Penobscot. Lastly, events which focus on sections of river specific to whitewater draw visitors both across the country and internationally. Not only does this increase economic attention to the area, it also encourages a community of paddlers come together to celebrate and preserve rivers such as the Penobscot.

Charles WAtkins, Dorchester, MA.
Any whitewater kayaker in New England knows that the W Branch Penobscot is one of the most pristine, wild, and beautiful runs in the country. For that reason, I am writing to inform FERC of the environmental, economic, and recreational value of providing releases on the Dryway and Millinocket stream. I am certain that if recreational releases were scheduled on the Dryway of the W Branch Penobscot, hundreds of paddlers from all over the country would attend, bringing money and life to the local community. As evidence, please see the Maine Whitewater Championship - a race on the W Branch that brings roughly 100 paddlers and many more spectators per year to race down the river.
My understanding is that Brookfield has proposed a virtual flow study based on testimonials and video footage to determine proper flows for the Dryway section and Millinocket Stream. I believe that this method would be less effective, less safe, and more costly than an in-person physical flow study. Whitewater paddling is an inherently physical and dangerous activity, so it is important that in-person representatives from the community are able to experience and evaluate potential flows in order to inform Brookfield's decision around recreational releases. Members of American Whitewater and the AMC have taken part in many physical flow studies in New England and across the country, and therefore are able to use them in the most efficient, safe, and productive way. I hope that FERC and Brookfield will hear the opinions of the local paddling community and work towards establishing a long-lasting relationship to benefit the people of northern Maine.

Ryan Waterhouse, Rochester, NH.
We would very much love regular recreational releases of the "dryway" section of the Penobscot river. Please please do everything in your power to bring this opportunity to a very special community. Thank you.

Brooks cannon, Biddeford, ME.
Hello, I am writing you to tell you how important it is to the state of Maine's residence, tourists and whitewater community that Ripogenus dam have guaranteed water flows in the summer, spring and fall for whitewater rafting and kayaking. This section of the Penobscot river gives many people jobs, purpose and recreation and we would like to keep these rights to use the put in points for recreation and commercial use as well. We would also appreciate it very much if there were scheduled releases from the dam itself so this beautiful section of whitewater is accessed more dependably.

Thank you for your consideration
Brooks cannon
River guide
Recreational whitewater kayaker

Brian Olas, Portland, ME.
I am writing this comment today regarding Docket P2572-133.

As a user of the West Branch of the Penobscot River as a private paddler for over 20 years, I wanted to advocate for a consideration of a more comprehensive flow study of the section of river known as the "Dryway" above McKay Station. The near mile long section has excellent whitewater qualities inside a gorge that has had little in the way of historical flow data to take into consideration. This section is a prime location to develop future whitewater activities that could bring in real economic activity to a struggling but upcoming part of rural Maine. Millinocket is a town that could benefit from additional eco tourist events such as a whitewater river race or canoe races on the lower section of the river.

Thank you for the opportunity to comment.

Brian Olas
North Yarmouth Maine

Brian Olas, NORTH YARMOUTH, ME.
My name is Brian Olas of North Yarmouth Maine, long time recreational user of the West Branch of the Penobscot River. As a part of my experiences inside the Penobscot River Corridor as a Maine Whitewater and Recreational Guide for 22 years now, I have long looked at the section of the West Branch of the Penobscot known as the "Dryway" for potential whitewater recreational opportunities. This section of the river has very little in the way of historical data flow information on record. This nearly one mile stretch above McKay Station is worthy of a flow study that could impact future economic activity in an area known for its up and coming eco tourism investments. Real opportunity exists for nationally sponsored kayak races to canoe races further down the river. In fact, this is the first year of a newly developed canoe race scheduled for June 2022. With the addition of the "Dryway" the Penobscot River contains some of the best whitewater on the East Coast of the US. The current flow study's provided do not detail this section in any meaningful way.

As a member of American Whitewater, I can appreciate when hydro relicensing comes under review. It gives us time to look at opportunities for the future of such recreational places like this one under review now. American Whitewater has been very successful in working with FERC to develop paddling opportunities all over the country. Places like the Gauley River in West Virginia now have very successful festivals that attract paddlers all over the world that bring real and lasting economic value to the community.

Thank you for the consideration of a flow study for the "Dryway"

Brian Olas
American Whitewater Member
Maine Recreational Guide
Private Whitewater Paddler

Nathan Warren, Plymouth, MA.
As a longtime whitewater paddler, former outdoor educator and high school teacher, and current professor of business, I wanted to urge the parties involved in relicensing the Ripogenus Dam to fully consider the needs of the whitewater community and benefits of whitewater recreation to the local and regional communities.

First, the “dryway” section of river is a unique resource with few comparisons. It deserves an on water physical flow study. I believe any opportunity to expand recreational possibilities and impacts on the local economy should be thoroughly studied before major rules are made. If the dryway section had recreational releases, I and many others would be more likely to travel from out of state to take advantage of recreational releases and paddle the Penobscot. I have already participated in many whitewater festivals and events around New England and the country. These festivals are often hosted around recreational releases and they are good for the paddling community and local economy.

Christopher Howe, kingfield, ME.
I’m writing on behalf of myself as a raft guide who has worked on the West Branch Penobscot River since 2009. I currently now manage North Country Rivers Penobscot, located at the Big Moose Inn just outside of Millinocket.
It is absolutely imperative for the local economy that at the very least Brookfield Renewable Power maintains current license agreements as was written in the 1996 License when it comes to flows for whitewater rafting below McKay Hydro Station. To limit or reduce any of these releases would have long-term detrimental impacts on the Penobscot commercial rafting industry, which has significant economic influences in Millinocket and the greater Katahdin Region.
Not only should we maintain what we already have, but we must also thoroughly study and properly assess all whitewater boating opportunities that are affected by Millinocket Lake Dam, Ripogenus Dam, and the Stone Dam.
Ever since the Great Northern Mill shut down in the early 2000s Millinocket’s economy has suffered. Outdoor recreation remains a huge asset to the town in providing direct income for many residents and businesses. Since recreation has already proved its economic power to the area for the last 20+ years it only makes sense for the Katahdin Region and Brookfield Renewable to further invest in and expand recreational opportunities in town.
The old Great Northern Mill site in Millinocket is being revitalized and thousands of square feet of industrial space are up for grabs thanks to an organization called Our Katahdin. This plot of industrial land has already attracted the attention of many big companies that are looking to invest and grow their businesses in Millinocket. One of them being Nautilus Data Technologies. Which is going to start construction on one of the world’s greenest large-scale data centers. They use the Penobscot River to create electricity and use cold water from the river to cool the computers which is revolutionary.
With large-scale investments and job availability potentially spiking in Millinocket for the coming decades that this license entails. Plus combine this with individuals and families continuing to move away from cities to more rural locations with widespread outdoor recreational opportunities. The Katahdin Region could use every bit of recreation we can to help draw in potential employees for these businesses and families who are looking to move to a place where they can work, live, and play in their backyard
The future possibilities and the history in this region make it essential that recreational boating opportunities affected by these 3 dams are thoroughly studied and assessed, so we can fully understand what it takes to provide new scheduled recreational whitewater assets to the area and what the long term beneficial effects could be with expanded recreational releases, for the economy of Millinocket and the wellbeing of its present and future youth and residents. A schedule of recreational releases from these 3 dams can literally facilitate a whitewater boater from complete novice to expert all within 45 min of Millinocket.
The most important aspect when thinking about the future implications of these releases is the amount of change that can happen in a community during the duration of this license agreement. Thinking back on the scale of change that has occurred in Millinocket since the current license agreement was filled in 1996 is imperative to the thought process here. When considering this new agreement we must acknowledge all future possibilities and the scale of positive change that can

happen for the Katahdin Region over the duration of this agreement.
Although it appears no current whitewater rafting outfitter wants to expand their business by offering an additional mile of class IV/V through the Dryway, a new owner down the road might. As a 14-year commercial guide and a manager from one of the top outfitters in the state, and someone who was rafted and kayaked all over the country. Commercial rafting in the Dryway is possible with the right water level from Ripogenus Dam and proper safety regimen on behalf of the outfitter. There has been only 1 attempt to officially determine the feasibility of commercial rafting in the section between Rip Dam and McKay Hydro Station. This took place over 40 years ago in the mid-80s when Great Northern Paper Company was attempting to build the Big A Dam. The lake behind the dam would have buried the best rapids on the West Branch of the Penobscot so they put together a test to check out the Dryway, which was unsuccessful and is an incredible story. However, this was again over 40 years ago when they were in floppy, non-bailing, rubber rafts. Today we have self-bailing rigid PVC rafts, a rigorous Guide Training, and testing program, and a completely different perspective on river running that has evolved over 40+ years of successful rafting trips in Maine. It is a fact that this license agreement will last beyond all the careers and lives of these first-generation outfitter owners. During the next 3 decades that this license will be in effect, almost all of the major outfitters will either close, consolidate, or fall under new ownership. If a new generation of commercial rafting is what is going to happen in Maine all future business expansions pertaining to commercial rafting and boating should be considered.
Brookfield has stated in their revised study plan that they want to use videos and pictures from the internet along with anecdotal data from paddlers to complete such flow studies. It is my strong belief that this methodology is completely insufficient to obtain proper data to make such lofty long-term assessments. Their proposed methodology would possibly be okay for a sort of short-term assessment. However, we are talking about a 30-year contract, and this length of time surely justifies the most thorough and accurate studies available so all parties involved can come to a fair and data-driven agreement.

Casey Tull, Grand Rapids, MI.
I have been fortunate to visit Maine 5 times now in the early summer season. The sole reason for my visits was because of the incredible nature the state offers, specially the whitewater. I firmly believe the natural flow of the water is a lot more crucial to the ecosystem than any amount of energy potentially produced. There's are many ways to provide energy to communities, but creating a river is unmatched to the power of nature. Thanks for your consideration.

Dan Bernard, South Portland, ME.
The flows coming out of Rip Dam have changed my life and the life of many others. They have created a recreational outing that occupies peoples' weekends and summers, challenges youth and adults alike to develop a wide range of technical skills, strengthens the economy of Maine and Millinocket by attracting tourists from all over the world, and generates a community centered around the whitewater that is one of the strongest groups of people I have ever met. This is all due to the water that flows and our access to it.

We cannot lose these rights. In fact, we must strengthen our relationship with the river.

For the next relicensing period, I would like to see:

-Guaranteed whitewater flows (at least 2000 cfs during the months of May - September) to allow rafting and kayaking and other boaters to reliably enjoy the river, recreationally and commercially.
-Scheduled Ripogenus Dam water release days providing whitewater flows for a handful of days every summer (at least 2000 from the dam), much like the Dead River releases or the Seboomook releases. This will provide an educational opportunity to study the effects of high water in the "dryway" portion of the river between the dam and the power station, and will most certainly attract hundreds of people from all over the country and beyond to harvest the beautiful whitewater through the upper gorge. It is an untapped resource that would be one of the best flowing stretches of water in the country. It's better than the Dead, it's better than the Kennebec, it's better than the rest of the Penobscot, and the water does not belong to Brookfield! Let's make it happen!
-Maintain all access points to the river that currently exist, no matter what!
-Allow private boaters to access the river resource without restrictions.

Thank you for reading and considering my comments. Looking forward to being on this river for the rest of my life!

Penobscot Mills Hydroelectric Project (FERC No. 2458

RE: In Support of Maine Department of Inland Fisheries and Wildlife's Request to Radio Tag North Twin Impoundment Landlocked Salmon

In its April 7, 2022 filing, the Maine Department of Inland Fisheries and Wildlife (MeDIFW) filed Comments on the Revised Study Plan for the Ripogenus Hydroelectric Project (FERC No. 2572) and Penobscot Mills Hydroelectric Project (FERC No. 2458). This recent MeDIFW filing repeated earlier requests to include radio tagging of North Twin Impoundment landlocked salmon (salmon) in studies proposed by the Licensee in the Revised Study Plan. This filing is in support of "Study Request 8".

MeDIFW Study Request 8: Landlocked Salmon Habitat Use/Spawning Study

Penobscot Mills Project

*MDIFW continues to recommend a landlocked salmon radiotelemetry tracking study be conducted in the North Twin impoundment. The goals and objectives of this study include:*

- *Track seasonal movements and behaviors of landlocked salmon (within and between the five connected lakes) via radiotelemetry.*
- *Determine the effects of annual Project drawdowns on the movement and behaviors of landlocked salmon within the North Twin impoundment.*
- *Identify landlocked salmon spawning areas within the North Twin impoundment.*

I fully support MeDIFW's Study Request 8 that includes radio-tagging as it is the only method of determining potential project impacts on salmon spawning behavior e.g., movement, accessibility to spawning areas, distribution, timing and

ultimately, success. Locating, enumerating salmon, and photographing the stream bed accomplish nothing. However, I recommend this procedure for the West Branch above and below the Ripogenus Impoundment (P-2572). Great Northern Paper studied North Twin Impoundment salmon population from 1978-1989 and the results are included in the 1992 license application. Initially, these studies (tagging, creel surveys) were designed to determine possible interaction between salmon in the river reach below McKay Station (P-2572) and the North Twin Impoundment. Beginning in 1985, fish and angler surveys focused on the North Twin impoundment. Radio tagging was in its infancy and small radio tags were still being developed. Therefore, salmon were collected with trap nets and jaw tagged before being released near the collection site. Recapture of tagged salmon was through creel surveys or by trap net. Both methods of capture and recapture are passive in nature. Each depends on where nets are set or anglers fish and the movement of the tagged salmon. The results of these studies were that large areas of the impoundment were unsampled. The 1980's salmon taggings did confirm that fish moved toward Nahmakanta Stream and West Branch during the fall. However, the time between the initial tagging and subsequent recapture was weeks, months, and even years. Therefore, GNP fisheries data collected during the 1985- 1989 Penobscot Mills relicensing effort <u>is unsuitable</u> in regards to meeting current MeDIFW North Twin Salmon Spawning study objectives.

The Licensee in its March 23, 2022 filing rejects MeDIFW's radio tagging proposal (10.0 Deviations from Requested Study) basically stating a number of unsupported reasons e.g., "*when, and where adult fish are sourced, available sample size, and prevailing impoundment levels at the time of the study. Source fish would need to be wild fish collected within the approximately 18,000-acre North Twin impoundment. There would be no way to know the natal stream origin of adults captured for tagging, and therefore where such tagged fish would be inclined to go to spawn, resulting in potential spawning tributaries being overlooked due to a lack of fish native to that particular stream having been tagged."* The Licensee misses the point and has likely not reviewed the 1992 license application. The North Twin impoundment is now managed for wild salmon, stockings were discontinued in 2017. In the unlikely event stocked fish are captured and radio tagged, aging (scale reading) would reveal their hatchery

origin. There are only two North Twin Impoundment tributaries with flow and size capable of supporting significant salmon reproduction. The Jo-Mary system offers a third possibility. As the study issue is spawning access and success, the natal stream is largely irrelevant.

,

It is clear that radiotelemetry is the only viable method of meeting MeDIFW's goal of determining "*seasonal movements and behaviors of landlocked salmon".* Collections of fish suitable for radio tagging e.g., wild, adult fish, is relatively simple and radio tracking will product thousands of data points over the four - eight week pre spawning and spawning periods. Both South Twin and Pemadumcook lakes have excellent trap netting sites and adult salmon collected during the 1980s exceeded one fish a trap net day. Given the relative ease of salmon collections, in order provide robust study results, I recommend that the final study plan requires the licensee to provide MeDIFW with an adequate number of radio tags. Without the use of radio tags, the MeDIFW study goals can not be met and time and resources wasted.

Spawning and spawning success, in this case landlocked salmon, is a critical factor in determining ongoing project impacts. Salmon are the principal, perhaps only, cold water fish species in the project area. Understanding the spawning behavior of salmon in the North Twin Impoundment waters will help the FERC staff balance existing uses. I fully support MeDIFW's very reasonable and much needed Study Request 8.

Thank you for the opportunity to comment.

Alexander Tragakes, Windham, ME.
Hello,
The "Dryway" is a speacial piece of the Upper West Branch of the Penobscot. Something I have only ever been able to witness from land on few occasions. This is certainly a respectable section of whitewater that deserves to be understood and appreciated by learning what flows offer what types of experiences to whitewater boaters. Understanding how flow rates affect these rapids is impossible to do from a camera. I believe it is absolutely necessary to conduct on water studies of this section of river by professional and private boaters to determine optimal flow rates for recreational possibilities on this section of the West Branch.
I believe that adding additional opportunities to host outdoor experiences in the greater Millinocket area can have a big impact on the local economy and the businesses that operate there. This study of new activities in the area has the potential to offer a bigger draw to the area and bring more visitors to local businesses. This also could offer an additional river section for hosting paddling events, which offer opportunities for even more people to visit this special area.
I live in southern Maine and new recreational releases on the Dryway section, hopefully at varying flow rates for different skill levels, would absolutely be a reason that I would come to Millinocket over other whitewater locales both in the state and in New England.

Christopher Howe, kingfield, ME.

I'm writing on behalf of myself as a raft guide who has worked on the West Branch Penobscot River since 2009. I currently now manage North Country Rivers Penobscot, located at the Big Moose Inn just outside of Millinocket. I want nothing but a prosperous and healthy future for the Millinocket Region, and this new license agreement and my proposals can play a much larger role in achieving this goal than any of us could ever imagine for the Katahdin Region.

Millinocket Stream is an incredible asset to the town of Millinocket that is completely underutilized. Its numerous mellow rapids, benign nature, and long smooth pools make it a dream whitewater run for the novice to intermediate paddler. Or an ideal venue for classes and education in whitewater kayaking, canoeing, paddleboarding, and swift water rescue.

The opportunities to expand recreational releases on the Millinocket Stream I think are quite appealing to the economic benefit of Millinocket, especially when considering such economic benefits compounding over a 30-year period. I also believe that releases can be managed relatively easily on the behalf of Brookfield. Millinocket Stream on a regular year dumps quite a bit of water down this reach each spring to maintain lake levels on Millinocket Lake. Often I've seen boatable flows on the Millinocket for a good chunk of May and June, due to the large watershed of the lake.

I believe it is entirely reasonable for Brookfield to consider scheduling out weekend releases on the Millinocket during the months of May, June, and possibly July when they already have to dump water during this period anyway especially since there is no direct Hydro energy production from this location. It seems possible Brookfield could just release flows on scheduled days so whitewater paddlers, education groups, commercial outfitters, outing clubs, event directors, and local school outing programs can plan in advance, market, and promote whitewater lessons, courses, outings, and events. Outdoor Sport Institute (OSI), a non-profit based in Millinocket offers whitewater kayaking lessons for youth and adults who would directly benefit from rec releases along with other registered Maine rec and fishing Guides, commercial whitewater outfitters, and school recreation programs. Outdoor Sports Institute director and I say that the learning environment on Millinocket Stream is perfect. Herein lies the very reason it is imperative Brookfield provides thorough, on water, and in-person flow studies. Because words are only words. I can go on and on about my perspective of how great this stretch is. However, when it comes time to officially determine and make further decisions in this process my words or the director of OSI's words are "anecdotal" data that has zero weight in any sort of real legal setting and can be written off as here say.

What separates Millinocket Stream apart from the other river reaches in the re-licensing and why it is so important is that it's available to a much broader demographic of people, especially youth. Maine currently has a healthy regimen of rec releases on the Penobscot and Kennebec Rivers which are class III and above Rivers. Adding the class I/II/III section of the Millinocket Stream will help complete a cycle of natural progression in Whitewater Kayaking in the state which will in turn create a sustainable economic return for all communities that are affected by such rec releases. For example: Johnny is in high school and wants to learn whitewater kayaking because he did the Kenduskeag Canoe Race with his uncle.

He convinces his parents to enroll him in the Outdoor Sports Institute Beginner whitewater course offered on Millinocket Stream. Johnny falls in love with whitewater in high school and decides to take a job as raft guide during the summers while attending college, while progressing his passion and skills in whitewater kayaking. Johnny obtains his degree and moves to Portland and gets a job at Maine Med. Johnny works hard and needs time to decompress on time off so he continues traveling to Millinocket to paddle on his favorite rivers he learned and spent so much time on. Johnny doesn't like going alone so he recommends classes with OSI to his co-workers, before you know it Johnny and his group of friends head up to Millinocket most weekends to take advantage of recreational releases while going out to dinner, buying groceries, staying at campgrounds and hotels in the community. Johnny progresses enough in his career to where he can afford a second home in Millinocket for his friends and family.  Eventually, Johnny signs up his kids for a beginner whitewater class that OSI is offering on Millinocket Stream and the cycle starts again. That is just one example of sustainable economic growth the Katahdin Region could see because of scheduled releases on Millinocket Stream. The economic benefits of such a regimen of releases on Millinocket Stream could have tremendous and far-reaching economic impacts on the town, outfitters, and other businesses.  Therefore recreational boating opportunities must be studied completely and thoroughly especially considering the duration of the license. Anecdotal data and content from the internet are insufficient when trying to gather solid data to understand the recreational opportunities downstream of Millinocket Dam. Brookfield must give incremental releases of water to a group of paddlers to best understand minimum and optimum flows, so parties involved can come to a reasonable data-driven agreement that will satisfy all stakeholders in the re-licensing of this watershed.

Thank you for the opportunity to comment,
Chris Howe

RE; North Twin Project P-2458-247

Comments and Study Requests: Great Lakes Hydro America Proposed Instream Flow and Habitat Assessment in West Branch Downstream of Stone Dam Study Plan

Great Lakes Hydro America (the Licensee) continues to emphasize energy production over fisheries and aquatic community's needs. The best example of this strategy can be found in the *Proposed Instream Flow and Habitat Assessment of West Branch Downstream of Stone Dam Study Plan*. The Licensee, with support of the Maine Department of Inland Fisheries and Wildlife's (MeDIFW) Enfield Regional Office, is suggesting that a "put-and-take" hatchery brook trout fishery should be the Flow Study's focus, and that the adult life stage should be used in evaluating habitat suitability. While not clear, it appears all life stages of landlocked salmon will be included and habitat requirements evaluated.

The Licensee is proposing an Instream Flow and Habitat Assessment in West Branch Downstream of Stone Dam Study that focuses on hatchery brook trout. A "put and take" brook trout fishery is not an achievable goal. In summary, the licensee is proposing a study of adult brook trout habitat requirements, ill-suited for local recreational demands; and a <u>hatchery product they can not provide</u>. Both are in contradiction to published MeDIFW landlocked salmon management goals

While the MeDIFW stocks Maine waters everywhere with brook trout, the mitigation program (Article 413) agreed to by the Licensee for Millinocket Stream has been an on-going failure since the early 2000s due to the lack of fish, effort, interest or all three. Namely, <u>there have been NO Millinocket Stream spring</u>

stockings of trout "1/3 to one pound" since 2010 (MeDIFW archival records are not provided on the website before that date). Brook trout stocked in October as the fishing season concludes provide very limited fishing opportunity and do not meet mitigation goals. The failure to meet the FERC Article 413 requirement of spring stockings of suitable size brook trout over an 11 year period is a 401 WQC violation. This failure also emphasizes the frugality of including stocked brook trout in the proposed West Branch Channel study. Now, the Licensee would have us believe that stocked trout are the way to go, and that this time we should believe that they will be able to follow through with License mandates. Natural (salmon) production is more dependable than Brook Trout stocking and an achievable MeDIFW goal.

Essentially conducting a flow study for a "put and take" brook trout fishery is an oxymoron as this life stage requires no flow. This study request makes no sense. There are ample stocked waters including nearby Millinocket Stream that provides both easy road and foot access. Historically, 1996-2001 Millinocket Stream stockings provided less than two weeks angling opportunity (see Great Northern Paper's creel survey files) and less in recent years as there are no spring trout stockings that met Article 413 guidelines. Brook trout inhabit a variety of waters including vernal streams, beaver Ponds, and small flowages, they require ZERO flow. Brook trout habitat suitability curves have no nose velocity requirement i.e., they do not require water currents, although trout do require water and depth. Under the Licensee proposed study parameters, the results are known. Low inflow, perhaps 25cfs will do the trick. This is not practical fisheries management and it contradicts MeDIFW's published goals and environmental analysis envisioned in the NEPA. FERC needs to act to ensure that all salmon life stages as well as macro-invertrabrate communities are evaluated and provide information that can be used in balancing the resources in this section of river.

The Licensee in its obfuscatory Study Plan for Instream Flow and Habitat Assessment in West Branch Downstream of Stone Dam fails to consider a number of abiotic factors that doom this bizarre unscientific plan. Flow records contained in the licensee's filing provide evidence of "spring/early summer" spill events, these events would "wash" downstream hatchery brook trout, ill adapted for life in the wild. In addition, the licensee has failed to consider angler and hatchery truck access to and from the study reach and then foot access along an alder lined

rocky riverbank that lacks foot tails that can not be reached without crossing the watered West Branch Channel. The 1996-2001 "success" of the nearby Millinocket Stream put-and take trout fishery was a result of easy angler access as anglers could easily drive to and then walk literally 100 feet to fish.

A few comments follow;

1.0 Study Requests

This section of the study plans states that "put and take" (hatchery) brook trout will be the focus of the study. As noted below, the selection of hatchery brook trout is worse than arbitrary and focuses on a life stage that needs little flow and then for only a two week period. This proposal clearly reflects the Licensee's continuing effort to find study outcomes that support extremely low flows in the channel below Stone Dam. The Licensee has developed an outcome and found a study fish (life stage) to produce the desired results. This is the exact opposite of the scientific approach of first conducting a study. FERC staff is clearly aware of the licensee's continuing attempt to choose hydro-electric generation over fish, aquatic communities and boating needs. There is no "balancing" in this study proposal.

2.0 Goals and Objectives

• *Evaluate the potential for alternative minimum flows in the West Branch below Stone Dam to support a seasonal coldwater sport fishery*

The Licensee is preemptively and arbitrarily setting its own study plan objectives and accompanying outcome. There is nothing "seasonal" about a future Stone Dam tailwater salmon fishery. Salmon of all life stages would thrive in the area below Stone Dam as do salmon populations presently/historically existing below North Twin Dam and the Millinocket facility. The information available (see Penobscot Mills 1991 License Application) demonstrates the West Branch Downstream of Stone Dam, with appropriate flow, can clearly support a "year-round" salmon fishery and juvenile salmon production and meet MeDIFW published salmon management goals set forth in **both current (2002-2021) and the (draft) FISHERIES STRATEGIC PLAN 2021-2035. Goals of these plans include;**

- **statewide management goals for landlocked salmon are to maintain the current distribution of principal fisheries for landlocked salmon, provide**

**for a diversity of fishing opportunities, maintain and where possible expand the contribution of wild salmon to the population**

**The 2022 plan adds;**

**Maintain or enhance existing (salmon) populations *(High Priority)***

*"Identify potential strategies—including regulation, partnerships, habitat modification, ….."*

***Maintain healthy and sustainable landlocked Atlantic salmon fisheries***

*"Advocating for in-watershed land and water management practices that maintain or enhance spawning and rearing habitats for wild populations, where populations are not overabundant*

I also request that macro invertrabrate suitability be added to the species study list. As any salmonid species (including any ephemeral stocked trout population) inhabiting the West Branch Channel will require food, this is a very basic and reasonable request. I suggest Hydrophyscid caddis, as they are both common to the drainage and are an important and widespread food source for salmonid populations inhabiting the West Branch Drainage (see Vol VIII table 34 of the Ripogenus Application and Vol VII Table 17 of the Penobscot Mills Application)

**3.0 Resource Management Goals**

*Due to changing MDIFW fisheries goals and growing angler pressures in the region, MDIFW is trying to establish a seasonal put-and-take fishery in this resource [Back Channel] to provide more angler opportunities. Given changing MDIFW management objectives for this resource since the original license was issued, MDIFW requests that minimum flows be re-evaluated at the Back Channel (MDIFW 2021a).*

I am a proud MeDIFW alumnus, and in my brief MeDIFW career and during my 25 years with GNP, I attended perhaps a dozen MeDIFW division meetings. Interesting formats, new ideas and old issues were discussed. Being a change in policy *(changing MDIFW fisheries goals*), the use of the West Branch channel as put-and- take trout water would have been a likely discussion topic. Any meeting notes from those division or other meetings would provide insight into this proffered disturbing change in management directions.

Brook trout are widely stocked in Maine waters, including the Millinocket area (see www.maine.gov/ifw/fishing-boating/fishing/fish-stocking). In my January 7, 2022 filing, I asked for documentation e.g., creel survey, angler questionnaires, of "Given changing MDIFW management objectives for this resource", namely the need for a "put-and-take" stocked brook trout fishery in a relatively inaccessible location. I realize that MeDIFW staff(s) have many mandated tasks however, these data have not been provided. Additionally, "establish a seasonal put-and-take fishery" is misleading. The product, hatchery brook trout stocked each spring prior to 2010, existed in the nearby Millinocket Stream (Article 413) for a week or two. By definition, "put and take" is ephemeral. The only parameters that need to be established, and these are serious questions, how will anglers access the rocky/boulder 2 ½ mile reach? What method will be used to get a hatchery truck across a wetted channel and then 2 ½ miles downstream over an abandoned 4 wheel drive road?

More importantly, MeDIFW's request for a "put and take" brook trout fishery defies current fisheries and management objectives stated in the 2002 and draft 2021 MeDIFW salmon management plans. These plans (published goals) include; producing wild salmon, enhancing habitat and creating riverine salmon fishing opportunity. What is the purpose of having peer reviewed state wide resource plans, regarding landlocked salmon in this case, if they can be arbitrarily ignored to meet power generation goals?

4.0 Study Area *The study area will be the West Branch from Stone Dam to Grand Falls (Shad Pond backwaters to the toe of Grand Falls).*

My understanding of the "flow study process" is that interested stakeholders are included in the process, including study site selection. As I participated in the 1989 study, I would like to be part of this process.

Aerial photos picturing the 1989 study sites are provided in the proposed study plans. It has been 33 years since I last visited this area. These are not the study sites I remember walking to. Could the Licensee kindly check study records including survey records and confirm the photos correctly show the two 1989 study sites?

5.0 Background and Existing Information; "*The overall Project area supports a productive and popular sport fishery primarily for landlocked salmon and brook*

*trout, supported by both stocking and self-sustaining populations, primarily at the North Twin (impoundment and tailwater) and Millinocket Lake (impoundment and in Millinocket Stream) Developments".*

Current fisheries data for the Penobscot Mills Project area are limited to a MeDIFW winter angler survey and very limited gill nettings, thus these statements are unsupported. Pre 2022 data on the North Twin Tailwater fishery have not been provided and 2022 data is desperately needed. Thus, the status of that once important North Twin tailwater fishery is totally unknown and should not be referenced. The only brook trout fisheries in project waters are maintained by stocking as there are no significant self-sustaining brook trout population within the project boundaries. However, MeDIFW routinely stocks many waters both within and outside the project boundaries with hatchery brook trout. The case for yet another water with stocked brook trout and poor access is extremely weak. It is even weaker when source hatchery fish (Article 413) are unavailable in May.

7.0 Methodology

After being included in earlier sections, salmon are excluded from the study, only brook trout were referenced. The Licensee need to clarify the role of all landlocked salmon life stages. I requested that all salmon life stages be included in an earlier filing and MeDIFW made a similar request in its Revised Study Plan comments of February 22, 2022 (Appendix B).

As noted above, my only other comment is that macro-invertrabrates flow, depth and substrates requirements be added to the modeling event and that Hydrophyscid caddis be include as a study species (Family in this case).

In summary, for the last seven months I have read licensee and agency filings that are subjective at best. This an evidentiary proceeding. Simply because the licensee or MeDIFW makes a statement doesn't mean it is accurate. Many of these statements are not backed up with data or formal written policy. The licensee and to a lesser degree MeDIFW, need to provide facts e.g., data, policy, when they comment on fisheries and aquatic communities subject to a 30 year FERC License. I ask that FERC require the licensee and MeDIFW to provide supporting data, rather than subjective thoughts when contributing to this ongoing process.

Thank you for the opportunity to Comment

Jesika Lucarelli, Millinocket, ME.
Jesika Lucarelli, owner/operator @ Great Mountain Guide Service

We are in favor and encourage flow studies be conducted so we may better understand the full potential and opportunities for Whitewater recreation between rip damn and McKay station, below Millinocket damn, and below the stone dam on Millinocket stream.
Our goal is to see adequate flow studies in these 3 reaches, done by professionals “on water” and not Have the study be conducted by testimony from the Internet. As a local guide service we support a new study for relicensing because the desire and need for recreational white water is in high demand. We want to see our local economy continue to benefit from the tourism attracted by these places. More accurate and up-to-date flow studies may result in the expansion of our businesses, and continued growth for local economy.

Ryan Reed, Kingfield, ME.
I am writing in support of recreational water releases for whitewater boating in the Ripogenus Dryway as well as Millinocket Stream. I am a member of American Whitewater and I fully support the comments submitted by AW and AMC regarding the Revised Study Plan. Creating more recreational opportunities in this area would be beneficial for both the whitewater paddling community and the local economy. Thank you for your consideration.

Benjamin Koehler, Orono, ME.
I am writing today both as an avid recreational user, and as an outdoors professional working on the rivers of Maine. The three sections that the Maine whitewater community would like to have flow studies for whitewater recreation are; The Dryway on the West Branch of the Penobscot, between Ripogenus Dam and McKay Station, Millinocket Stream, and the dewatered section of the West Branch of the Penobscot between Quakish Lake and Shad Pond.
The Dryway on the West Branch of the Penobscot is one of the most quality, continuous class 4-5 sections in the state. When paired with the Gorge Crib section downstream of the Dryway, it is hands down the best dam release whitewater in the northeast. This section of whitewater could be a huge economic and recreational asset to the nearby town of Millinocket, but currently no releases are scheduled for the Dryway, and when it does run Brookfield makes no effort to publicize the release. It is essential for the economy of the area that FERC orders Brookfield to complete a Whitaker style Whitewater Boating Flow Study on this section.
Millinocket Stream is a quality class 2-3 section that ends right in Millinocket, a town that is transitioning from an industrial economy to an outdoor recreation economy. Millinocket has great access to class 4-5 whitewater on the West Branch, but lacks a venue for beginner boaters to hone their skills. Having summer releases on Millinocket Stream would provide recreation for boaters of all skill levels, give local outdoor educators such as Outdoor Sport Institute a section to provide instruction, and be especially beneficial to local children who aspire to become competent boaters. It is essential for the economy of the area that FERC orders Brookfield to complete a Whitaker style Whitewater Boating Flow Study on this section.
The dewatered section of the West Branch of the Penobscot between Quakish Lake and Shad Pond has a short but quality class 3-4 gorge, and a beautiful waterfall. Currently next to no flow is sent down this natural river channel, as it is diverted into the hydro project at the Millinocket mill site. Putting water back into this river section would provide another great stretch of whitewater, right in Millinocket, and would provide a great intermediate step for improving boaters between Millinocket Stream and the West Branch. Brookfield alludes to a flow study that was done on this section last time licensing was done, however no one at Brookfield can locate the study. It is essential for the economy of the area that FERC orders Brookfield to complete a Whitaker style Whitewater Boating Flow Study on this section.
In conclusion, existing knowledge of these sections is anecdotal, and needs to be studied formally so that FERC can make an informed decision about the future of whitewater recreation in the Millinocket area.

Re: The Ripogenus and Penobscot Mills Projects P-2572 and P-2458

Great Lakes Hydro America's failure to meet 401 Water Quality Certification Articles and Protection, Migration and Enhancements Measures during 2021.

Great Lakes Hydro America (the Licensee) initiated the Licensing of the Ripogenus (P2572) and Penobscot Mills (P2458) Projects on June 8, 2021. During this process the Licensee has submitted numerous filings that demonstrate their failure to follow 401 WQC prescriptions. Additionally, the licensee has ignored measures suggested in the 1996 EIS and then listed them in the Preliminary Application Document (PAD) as Protection, Enhancement and Mitigations (PE&M) measures. The Licensee needs to be held to both legal standards and enhancement measures so often referred to in the PAD and subsequent filings. Stating that nothing has changed and "everything is great", simply is not supported by the March 23, 2022 "flow and elevation" filing and the Maine Department of Inland Fisheries and Wildlife's (MeDIFW) Chesuncook lake (Ripogenus Impoundment) October 8, 2021 filing. I contend that the Licensee needs to correct operating procedures that clearly violate 401 WQC articles or contradict PE&M statements made in the PAD. This filing requests that FERC immediately take the necessary actions to correct present and future operations that are impacting fish and aquatic communities and angler use and success in the Ripogenus Impoundment and all reaches of the West Branch. The areas of concern are;

- Article 402 – Ripogenus Project, Upper Gorge July-September 30 flows
- Article 406 - Ripogenus Project, Holbrook Bypass Channel Salmon Spawning and Nursery Flows
- Article 408 – Penobscot Mills Project, Irregular Flows
- Article 413 -Millinocket Stream, Spring and Fall Brook Trout Stockings

- The Use of the Water Management Plan

Upper Gorge:

Former MeDIFW Regional Biologist, Paul Johnson filed (October 8, 2021) comments on the PAD, noting that the licensee's present practice of providing surface flow into the Upper Gorge were not meeting the objective of Article 402, section 401 of the Clean Water Act. MeDIFW echoed this concern in its October 8, 2021 filing.

> "*It was the intent of MDIFW that the flows in the Upper Gorge would originate from a deep gate and provide a cool water attraction flow as adult salmon reached the upper river in July. However, the water is released from a sluice (surface) gate which is warm water. This water is warmer than the water passing through McKay Station into the river and is therefore ineffective as an attraction flow*."

Brookfield Renewable Energy/ Great Lakes Hydro America is a competent and well-run organization. During *due diligence* the Licensee surely became aware of goals and operating necessities required by License articles and PM&E measure presented in the 1996 EIS and the resulting FERC license. Still, despite complaints and study requests, the Licensee continues to ignore issues raised in numerous stakeholder filings and a very reasonable MeDIFW request has been ignored. However, this "pales in comparison" to the fact that the Licensee's lists the Upper Gorge flow as a PM&E measure when recent Upper Gorge flows are by surface discharge. The resulting flow act as a salmon repellent rather than an attraction flow. The existing Upper Gorge flow regime is exactly opposite of the MeDIFW request.

In recent years, the July 1 -September 30 period, flows into the Upper Gorge were 90 cfs of surface water though a "log sluice" gate. The assumption was that the remaining flow needed to meet the 100 cfs requirement was from leakage (12 Cfs recorded during a full pond 1991 measurement). However, the license says release. This implies an action, in this case, opening a gate. Leakage is passive and beyond control of the licensee and in fact, there are no current data reporting the amount of (any) leakage and change in (any) flow volume as the Ripogenus Impoundment head is reduced.

The present licensing schedule appears to be delayed and field collections are unlikely to be initiated by May 1, 2022. Another year's delay and another year of continuing impacts. During this transition period FERC can act to bridge the gap, by ordering the Licensee to either provide Upper Gorge flow through a deep gate or by requiring the Licensee to siphon off water (say 10-15 cfs) from below the McKay Station intake structure, say 55 feet below full pond elevation. Either method will reduce the Upper Gorge stream flow temperature. A return to the initial MeDIFW goal and conditions of Article 402 is a simple operation.

.Holbrook Bypass Channel:

The Holbrook Bypass Channel, Article 406, was designed at the request of MeDIFW in order to mitigate for the lack of young-of-the-year (YOY) salmon habitat in the West Branch below McKay Station. Two intake pipes were buried under a rocky berm along the northeast side of Holbrook Pool. One pipe with an adjustable valve, allowed for flows of 35 (June 1st) or 65 cfs (October). Mandated monitoring studies required in Article 406 and conducted during the years of "relatively stable base flows" determine that this mitigation measure was a success. Adult salmon spawned in the bypass channel and subsequent YOY production was excellent in earlier years. Monitoring studies ended in 2001.

During the summer and fall of 2021, low McKay Station flows resulted in reduced flow into the bypass area. On September 14, 2021 Licensee's staff photographed the upper Bypass Channel at a reported station flow of 1000 cfs (see the Licensee's September 30, 2021 filing). The two pictures show a flow that lacks surface turbulence and riffles, conditions needed for optimum YOY salmon production. Looking downstream from the intake gates, a long, flat stretch with an "unbroken" surface is apparent. Such waters are not suitable for YOY salmon and salmon production is lost or reduced under a 1000 cfs flow regime.

By November 2021, Holbrook bypass low flows became effectively no flow, and this very limited flow was not suited to spawning AND overwintering survival of eggs. The 2020 spawning year class and resulting 2021 salmon YOY production was lost during late summer and early fall low flow events. Then November 2021 salmon spawning was lost due to fall and (2022) winter dewatering, this will result in NO 2022 salmon YOY production. Two years of Article 406 mitigation lost and the West Branch salmon population will suffer in the coming years. While 2021 was a "dry

year", the Licensee was in complete control of Ripogenus storage and McKay Station Flow. On May 15, 2021 the Ripogenus Impoundment elevation was 933.77 (see March 23, 2022 filing) or about 23 BCF, the upstream Storage Project (P-2634) presumably in full license compliance, contained another 9 BCF. An additional 8+ BCF of inflow would eventually contribute to storage during the May 15-September 15 period. The resulting 40 BCF was enough water to meet both hydroelectric and PM&E measures. Instead, the Licensee chose to generate and drain the Ripogenus Impoundment, and eventually the West Branch, rather than meet PM&E measures so often cited in the PAD and subsequent filings. The FERC compliance section should require the Licensee to meet the WQC Article 406 condition as well PM&E measures it now boasts of so frequently.

Daily low evening flows e.g., 1000 cfs, not only impacted the above referenced salmon nursey area (both in the bypass and in downriver areas) but aquatic communities, fisheries and angling opportunity. The foundation of the 1992 Ripogenus Project License Application was "relatively stable base flows" and the accompanying "two wheel" (turbine) 2000 cfs flow when Mill energy demands were low. This was an environmentally proven mode of operation. The fishery below McKay Station was a "world class" fishery. MeDIFW referred to this river section as a "Destination Fishery". FERC now has an opportunity to protect the fish and aquatic insects below McKay Station by requiring the licensee to adhere to article 406 standards. Mandating McKay Stations discharges that provide a June 1st flow of 35 cfs into the bypass stream will meet multiple goals including downstream fish and aquatic communities' needs.

Penobscot Mills Project Flows

The 1996 License was based on Great Northern Paper's historical relatively stable West Branch base flow operations. It appears that the Licensee has changed from historical operations into a peaking mode in waters downstream of North Twin Dam and extending to the Medway Impoundment. For example, during August 12 and 13 of 2021, North Twin Dam outflows peaked at 3943 cfs before returning to the licensed minimum of approximately 2000 cfs (the Licensee's March 23,2022 filing). These peaking events appeared in other years and all other facilities. While well within the license WQC conditions, such flows are not "relatively stable" and impact fisheries and aquatic communities. The Licensee has yet to file the

requested hourly flow and elevation records for each facility. These records should be made public. A review of licensee' March 23, 2022 filing of *Daily operations data* listing "min.station" and "max.station" records indicate that there were numerous peaking flows events but the time frame is unknown. Minimum and maximum station flow differentials of 1000-1400 cfs were common below all facilities. FERC should require that the Licensee provide the requested hourly flow information, these data will demonstrate any daily flow fluctuations in response to energy demands.

During low flow periods, the West Branch provides much of the mainstem Penobscot River's flow, perhaps 90%. Thus, flow management of the West Branch (Penobscot Mills Project) impacts down river fisheries and aquatic habitat downriver of the Weldon Station (Mattacecunk Project P-2520). The entire mainstem Penobscot River below Weldon Station is considered critical habitat for the federally listed Atlantic salmon. The USGS West Enfield flow records, when viewed in graphical form, suggest upstream peaking events. The impact(s) of Penobscot Mills Project flow management on critical Atlantic salmon habitat in the mainstem Penobscot River should be considered.

Millinocket Stream, brook trout stocking

Article 413 requires *"The licensee shall implement an upgraded spring and fall brook trout stocking program to provide a seasonal fishery in Millinocket Stream. Each stocking shall consist of about 500 fish ranging in size from 1/3 to one pound,…."*.

Initially, Millinocket Stream hatchery brook trout were supplied by a private source rather than a public source, MeDIFW**.** A review of MeDIFW stocking records dating back to 2010 revealed that the licensee has been unable to meet Article 413 requirements in the last 11 years. The Licensee has consistently failed to meet the "spring and fall brook trout requirements" as spring stockings of trout "*1/3 to one pound*" have not occurred. The 2021 stocking of small, but catchable, 10 inch trout was an improvement but still failed to meet WQC Article 413 requirements. There were also a number of May stockings, when two inch fry were stocked. These efforts also failed to meet Article 413 requirements. Stocking brook trout fry in Millinocket Streams makes no biological sense. The reason for stocking brook trout fry is unclear. This alarming failure to meet an important

Article 413 mitigation measure was not revealed in any of the Licensee's frequent filings. I urge FERC to correct this licensee violation by requiring the Licensee to stock "*1/3 to one pound*" brook trout in the spring.

The Use of the Water Management Plan:

The Licensee has mostly ignored the 1996 Water Management Plan (WMP) and arbitrarily set up its own water management plan; a peaking operation driven by the market for electric power that conflicts with environmental needs. Circa 1990, Great Northern Paper hired highly credentialled Dr Nathan Burris PhD to develop a Water Management Plan that evolved into a Water Use Plan (WUP) for the West Branch drainage. The WUP was used in the early years of the current license but may have been abandoned by the Licensee. I say "may" because the licensee sometimes claimed to follow their own water management scheme while at other times referring to the WUP. The best and perhaps only example of "picking and choosing" water management guidance, the WUP, or using their own mysterious water management plan that ignores stated license goals is found in a footnote to Table 4.4-1 of the PAD;

*"The whitewater flow for each month from May through September is determined on the first day of each month based on an analysis of Total Available Water as described in the Water Use Plan in the application for new license filed with the Commission on December 17, 1991"*

There are no upper flow limit associates with "whitewater flow" releases. The March 23, 2022 flow spreadsheets demonstrate that during 2021, the Licensee routinely operated in a peaking mode, e.g., 3000 cfs, during periods before, during and after boaters were on the river. Market driven energy needs for peaking are simply called "Whitewater flows". MeDIFW questioned water management in its October 10, 2021 filing, questioning 3000 cfs flows during draught conditions. *"MDIFW observed on several occasions in the winter and summer of 2021 that the Licensee was indeed running in excess of 3,000 cfs when lower flows were required by the license;*". By August 2021 Ripogenus Impoundment storage was clearly being rapidly depleted and many PM&E measures threatened. Still the Licensee continued to operate in a peaking mode. The WUP, including "*an analysis of Total Available Water as described in the*

*Water Use Plan"* referenced in the PAD, was clearly arbitrarily ignored in the summer of 2021.

The PAD states that the licensee measures snow in late February/early March and uses the result to "manage" storage. The relevance of "snow depth" is not clear. The critical factor relating to potentially available storage, is water content in the snowpack. Equally bewildering, is the apparent lack of knowledge of the North Branch and South Branch (hydraulically controlled by the Canada Falls facility) USGS monitoring stations and the unwillingness to use real time inflow data. A review of the 2021 USGS North Branch station and to a lesser degree the (hydraulically controlled) South Branch Station flow data provides clear and irrefutable evidence that the Licensee violated the "or inflow" provision of the Ripogenus' s Project Article 406 during the late summer and early fall of 2021.

"*The 1991 Water Use Plan (i.e., the licensee's proposed operation alternative) was developed prior to issuance of the Projects' existing licenses and was the basis for the operational requirements included in the Projects' 1996 FERC Licenses. However, as compared to the Water Use Plan, the Projects' current operations are defined by the requirements of the Projects' licenses. Therefore, the 1991 Water Use Plan is not a "management plan" consistent with other management plans resulting from a relicensing proceeding"* (PAD 1-12).

The above quote is simply the Licensee's opinion. Other than the obvious change to a peaking operation (that the Licensee has yet to acknowledge), the Licensee provides no explanation of the above statement. I have seen no FERC filings where the Licensee has filed statements concerning abandonment of the FERC license guidelines. The change in operation was a deliberate business decision to maximize generation. In the PAD the Licensee states "*Therefore, the 1991 Water Use Plan is not a management plan consistent with other management plans resulting from a relicensing proceeding*." The WUP is the foundation of the 1996 Licenses. FERC, in the 1996 EIS, found the WUP compatible with existing fish and aquatic communities and "boating" needs while at the same time meeting other required PM&E measures. The Licensee implies nothing has changed but then states in the PAD that the WMP is no longer valid. So, what has changed to the degree that the WUP is not "consistent with other management plans"? The Licensee referenced water management frequently and boasted about it as a

PM&E measure. Thus, it is obvious that the Licensee has some type of a water management plan with starting and ending points. However, "generate and drain" is not a water management plan as the end points are a dry impoundment and an environmental disaster. It is time for the Licensee to share the parameters used in managing storage and flow in all project waters with the agencies, stakeholders and FERC.

It is time to develop a new Water Management Plan. MeDIFW in its October 8, 2021 filing echoed a similar sentiment, *"We view this upcoming relicensing process as an opportunity to review and fine tune the water management for the Ripogenus Project."* Simply stated, at this time, there is simply no peer reviewed water management plan for the West Branch for the West Branch between McKay Station and the Medway facility. In its frequent filings, the licensee constantly talks of water management and then demonstrates that none exist. It is obviously that in the case of fisheries, aquatic communities, loons, camp owners and boaters, their needs were not considered during 2021 and other years. The West Branch River system is out of balance. As soon to be mandated 2022-2024 studies are completed, a list of competing needs will be developed. In order to balance the needs of various users, FERC staff will require information on available storage and flow requirements. Without a peer reviewed water use plan, FERC staff's task will be impossible.

Despite the Licensee's warning of another "dry year" in its March 9, 2022 filing, heavy rains have greatly improved storage conditions and the impoundments are filling or already full. To those of us involved in this licensing(s), we are happy to see the Licensee enjoy an apparent (at this time) "wet year". Wet years are good for hydroelectric generation, and even better for fish and aquatic communities. A win for all parties. Still, environmental concerns remain. As an interim measure, I urge FERC to require that Holbrook bypass flows be maintained as envisioned by Article 406. This can be accomplished by ordering that minimum McKay Station operating flows be set between 2000 -2200 cfs. I also request that FERC implement MeDIFW's ramping request (October 8 2021 filing) of a 25% change per hour outflow below all project facilities. Ramping rates are common to all new FERC licenses/401 WQCs and the Licensee is required to ramp at Caucomgomoc Lake Dam (P-2634), Stone Dam (P-2572) Article 412 (7), and the Magpie River (Ontario, CA) to name a few facilities. A new license is at a minimum four years

away. The ongoing impacts to fish and aquatic communities needs to be corrected. Current project operations are out of balance, heavily skewed to power generation. Requiring the Licensee to adhere to the many license articles and PM&E measures it so often boasts of would be a good start.

Thank you for the opportunity to comment on the many license violations that resulted from Licensee's 2021 operations of the Ripogenus and Penobscot Mills Projects.

***Via Electronic Filing***

Kimberly D. Bose, Secretary
Federal Energy Regulatory Commission
888 First Street, NE
Washington, DC 20426

**Subject: Ripogenus Hydroelectric Project (FERC No. 2572-133)**
**Penobscot Mills Hydroelectric Project (FERC No. 2458-247)**
**Response to Stakeholder Comments on Revised Study Plan**

Dear Secretary Bose:

Great Lakes Hydro America, LLC (GLHA), a subsidiary of Brookfield Renewable and Licensee of the Ripogenus Hydroelectric Project (FERC No. 2572) and the Penobscot Mills Hydroelectric Project (FERC No. 2458) (collectively referred to as the "Projects"), herein files with the Federal Energy Regulatory Commission ("FERC" or "Commission") responses and clarifications to select stakeholder comments on the Revised Study Plan (RSP) for the relicensing of the Projects. The Projects are located on the West Branch of the Penobscot River and Millinocket Stream in Piscataquis and Penobscot Counties, Maine.

On June 11, 2021, GLHA filed the Notices of Intent and Pre-Application Document (PAD), which initiated the formal relicensing proceeding to obtain two separate new licenses for the continued operation of the Projects through the Commission's Integrated Licensing Process (ILP). Subsequently, FERC issued Scoping Document 1 (SD1) on August 10, 2021, and held daytime and evening virtual scoping meetings on September 9, 2021.[1] Additionally, on the afternoon of September 9, 2021, GLHA hosted a virtual environmental site review. On November 22, 2021, FERC issued Scoping Document 2 (SD2). Also on November 22, 2021, GLHA filed a single Proposed Study Plan (PSP) for the Projects. GLHA hosted a two-day virtual PSP meeting on December 15 and 16, 2021. On March 23, 2022, GLHA filed a RSP for the Projects.

Via letter dated April 1, 2022, the National Marine Fisheries Service (NMFS) requested an extension of time to file comments on the RSP. Via letter dated April 7, 2022, FERC approved an extension of time until April 28, 2022, for stakeholders to file comments on the RSP and until May 13, 2022, for FERC to issue the Study Plan Determination for the Projects. Given these extensions of time, GLHA is providing clarifications and responses to select stakeholder comments regarding the RSP. GLHA believes that this additional information will provide stakeholders with additional needed information and support the Commission's development of the Study Plan Determination.

[1] As specified in SD1, the Commission did not conduct in-person public scoping meetings or in-person environmental site reviews due to concerns with COVID-19.

**April 1, 2022 Letter filed by American Whitewater and Appalachian Mountain Club (AW-AMC)**

**AW-AMC Comment on Whitewater Boating Assessment Study**

Specific to the West Branch Below Stone Dam, SD2 and the comments of AW, AMC and Maine Department of Conservation, Division of Parks and Public Lands on the PSP requested that the West Branch below Stone Dam be assessed to adequately evaluate the needs and opportunities related to this resource for whitewater boating and other recreation. In the RSP, related to Stone Dam in section 5.0, AW and AMC believe the licensee is seeking to justify their lack of interest in following the Whitaker 2005 methodology by arguing that flows needed for such an analysis cannot be provided. AW and AMC find this assertion to be unclear and inconsistent with other publicly available information related to the operating parameters of the Stone Dam.

Though the licensee claims that the inflatable flashboards that have replaced the old gate structures at Stone Dam prevent the licensee from conducting a controlled flow study in this reach, AW and AMC find this contradictory to filings on this project to the Low Impact Hydropower Institute in their application and the reviewer's report in that docket (https://lowimpacthydro.org/lihi-certificate-167-millinocket-dolby-hydroelectric-project-maine/). Regarding the Stone Dam inflatable structure, the LIHI docket notes that Stone Dam may be used to attain the 2,000 cfs minimum flow downstream of the Millinocket Project when the Millinocket project is offline. The LIHI docket notes that, "*During periods of high seasonal flows or whenever abnormal conditions occur such that turbine flow [at the Millinocket Project] cannot be passed to achieve the 2,000 cfs minimum flow, the pneumatic rubber flashboard system [at Stone Dam] is deflated to release flows in an expeditious effort. When this occurs, a two-minute siren warning is initiated and a safe flow of 200 cfs is released for fifteen minutes. Increases of 400 cfs per hour are made until either the required downstream flow is met, the elevation at Stone Dam falls to 459.45 ft msl or the pneumatic rubber flashboard system is fully deflated. The ramping down of flows in the Back Channel is initiated once turbine hydraulic capacity is restored or seasonal flows start returning to normal.*" Provided that this information is accurate, it appears that Stone Dam can be operated in such a manner to assess whitewater paddling with an on-water component as part of the study if deemed necessary after Whitaker Level 1 study through single flow or multiple flow on-water study. This should be corrected in the Study Plan Determination.

**GLHA Response**

GLHA has reviewed the above-referenced information from the LIHI docket regarding the operation of the pneumatic rubber flashboard system at Stone Dam and provides clarifying information herein.

GLHA notes that LIHI docket information is consistent with the Water Management Plan for the Penobscot Mills Project, filed for Commission approval on April 9, 1997. The plan had been prepared in accordance with License Articles 401, 402, 403, 404, and 408 and was approved by Commission order on September 3, 1997.

The pneumatic flashboard system at Stone Dam is operated in support of public safety and to address abnormal operations (e.g., unplanned outages). Whereas GLHA operates the pneumatic flashboard system as such, it should not be interpreted that sufficient control of flows from Stone Dam exists to support a controlled flow study.

Minimum flows are released from Stone Dam using a procedure that incorporates ramping to avoid public safety concerns associated with an abrupt increase in flows downstream of Stone Dam. To provide the approximately 200 cfs public safety ramping release from Stone Dam, the control center partially deflates the pneumatic flashboard system. Prior to and during this deflation, the control center sounds the public safety siren for 6 minutes to notify downstream users of the increased flow entering the stream channel. During the public safety ramping release, the control center also observes via cameras the water flowing over the pneumatic flashboard system for the 15-minute duration to visually verify the deflation and estimated flow.

While the pneumatic flashboard system has a general gate discharge curve associated with it, the system, unlike pneumatically actuated gate systems, does not deflate consistently and, as such, does not release precise outflows. Although the pneumatic flashboard system at Stone Dam cannot release precise outflows, it is manually adjusted (as there is no automatic control) by the control center to maintain a stable head pond in compliance with the Penobscot Mills FERC license. As a result, the pneumatic flashboard system at Stone Dam is not capable of consistently providing the precise or sustained flows necessary for conducting a controlled flow study in this reach.

**AW-AMC Comment on Recreation Study**

Though AMC and AW appreciate the inclusion of a recreation user intercept surveys in the study methodology, we request that the study methodology also include an online survey, input from a stakeholder working group, and key person interviews with organizational representatives from user groups, representatives of camp owners and other recreation related interests, such as outfitters. It is not practical for our organizations or, for example, a camp owner on one of the lakes, rivers, or upland areas to be expected to travel to a FERC-approved recreation site to complete the survey, nor does the survey instrument speak to the feedback of these audiences as a broader representation of the needs, opportunities and issues that would be brought forward by these audiences.

**GLHA Response**

GLHA would like to clarify that the proposed study includes an online version of the recreation user survey. The survey boxes that GLHA will be deploying at each of the Project recreation sites will be displaying a QR code which, when scanned with a cell phone, can be used to find an online version of the recreation user survey. This method has been used effectively at numerous other hydropower projects and is a good way to provide online access to the survey.

Regarding the availability of the recreation user survey (or the QR code to complete the survey online) by those accessing the Project impoundments from locations other than the Project recreation sites, GLHA notes that the recreation user survey is focused primarily on understanding how the FERC-approved Project recreation sites are being used, and whether the facilities and amenities provided at the sites are functioning well and meeting their intended purpose. For this reason, it is appropriate to provide the surveys and QR code for online survey access at the Project recreation sites. That said, in their comments on the RSP, the Bureau of Parks and Land (BPL) asked how users of the remote campsites will be surveyed. To address this concern, GLHA will work collaboratively with BPL to install additional survey boxes at the boat launch locations indicated by BPL that are primarily used to access the remote campsites on the Ripogenus impoundment.

**April 7, 2022 Letter filed by Maine Department of Environmental Protection (MDEP)**

**Comment on Fish Assemblage Study**

In its comments on the Proposed Study Plan, the Department requested a Fish Assemblage Study that would be used to demonstrate, in part, whether the Projects meet applicable water quality standards. Specifically, the impounded waters must support all species of fish indigenous to those waters. The results of the Fish Assemblage Study would also be used as evidence that could demonstrate attainment of the designated use of habitat for fish and other aquatic organisms.

In the RSP, Great Lakes does not adopt the Department's requested Fish Assemblage Study, and instead proposes to conduct a Fishery Assessment as part of the Impoundment Aquatic Habitat Assessment component of the Water Quality Study. The Fishery Assessment would not involve any scientific sampling of fish populations. Instead, it would rely on existing information and interviews with various parties.

Although Great Lakes did not directly address the Department's request in its rationale for not adopting the Fish Assemblage Study, it did address a similar study request from a stakeholder group. Great Lakes appears to base its decision not to adopt the Fish Assemblage Study on its assertions that existing information is sufficient [section 5.9(b)(4)], that study results are not likely to inform potential license conditions [section 5.9(b)(5)], and that the study methods proposed by the stakeholder group (gill netting) are not consistent with generally accepted practice in the scientific community [section 5.9(b)(6)].

The Department disagrees with Great Lakes' assertions. First, existing information would not be sufficient to demonstrate that the Projects are currently meeting water quality standards. Historical and anecdotal data could be useful for fisheries managers, but it is unlikely to provide sufficient, defensible data for the Department to determine that the Projects' currently support all indigenous species of fish. Comprehensive, scientific sampling of fish populations would provide sufficient data to draw conclusions about the Projects' effects on water quality [section 5.9(b)(4)]. Second, the results of a Fish Assemblage Study would directly inform potential conditions that the Department could require in any Water Quality Certification it would issue for the project. Study results would be used to demonstrate attainment of

water quality standards related to fish populations in addition to providing evidence that the Projects meet water quality standards related to aquatic habitat more generally. If evidence of nonattainment is found, the Department will use the study results to inform the development of measures to mitigate for the Projects' effects on water quality. This is critically important to the relicensing proceeding, because FERC must include Water Quality Certification conditions in any new licenses for the Projects [section 5.9(b)(5)]. Third, the Department did not provide specific methods in its request since this type of study is commonly conducted in many FERC relicensing proceedings. Great Lakes' response focused on their concerns with the stakeholder group's proposed methods for collecting fish samples (gill netting). Great Lakes did not discuss any other generally accepted, and more commonly used, practices that the scientific community typically uses in fish assemblage studies, such as electrofishing. Due to this omission, Great Lakes' response did not fully address the study criteria, nor does it provide a basis for Great Lakes to not adopt the Department's requested study [section 5.9(b)(6)]. For these reasons, the Department requests that FERC determine that Great Lakes must complete a Fish Assemblage Study.

**GLHA Response**

To demonstrate that the Ripogenus Project meets applicable water quality standards, GLHA proposed in the RSP to complete additional data review and meet with regional Maine Department of Inland Fisheries and Wildlife (MDIFW) biologists who have current, first-hand knowledge of the existing Chesuncook Lake fishery to identify and describe indigenous species that are known to occur. In addition, GLHA proposed a macroinvertebrate study at the Ripogenus impoundment and aquatic habitat studies at the North Twin and Millinocket Lake impoundments to determine if aquatic life standards are supported in the Project areas. GLHA did not propose aquatic habitat assessments for the Millinocket (Quakish Lake and Ferguson Pond), Dolby, and East Millinocket impoundments because they are operated in run-of-river mode, which does not result in impoundment drawdowns under normal operations; MDEP typically does not require impoundment aquatic habitat studies for projects operated in run-of-river mode.

As described in the RSP, indigenous fish species known from the region include brook trout, yellow perch, white sucker, rainbow smelt, longnose sucker, lake whitefish, lake chub, golden shiner, fallfish, creek chub, common shiner, burbot, brown bullhead, and blacknose dace (Lakes of Maine 2022[2]). Most of these species are common throughout Maine waters. As described in Table 5-4.3 of the PAD, GLHA has previously documented that the Ripogenus impoundment supports these indigenous game and non-game fish species. The Licensee collected 18 species of fish in the Ripogenus impoundment as part of the last relicensing, including all known indigenous game and non-game fish species.

GLHA notes that the MDIFW, the principal state resource agency responsible for fisheries management and monitoring, did not request site-specific fisheries studies given the considerable

[2] Lakes of Maine. 2022. Database of Maine Lakes. Online [URL]: https://www.lakesofmaine.org/index.html?r=1650984792. Accessed April 14, 2022.

body of knowledge and their overall understanding of the fish assemblage in the Ripogenus Project area. MDIFW noted in its comments on the PAD (October 8, 2021) that there is an "*extensive history of inland fisheries studies associated with the Ripogenus Project completed in preparation for the 1996 license, and these studies need not be duplicated unless there are identified data gaps, or changes in operation that may impact the fisheries resources*." MDIFW also noted that the "*inland fisheries management goals for the Ripogenus impoundment and river have not changed since the last license was approved*."

In addition to the fisheries information collected during the previous relicensing effort, MDIFW has indicated that there is additional existing information on fishery resources in Chesuncook Lake of the Ripogenus impoundment that demonstrates the waterbody continues to support the indigenous fish species. GLHA spoke to the MDIFW Regional Biologist responsible for fisheries management at the Ripogenus Project on April 15, 2022, to discuss the fishery assemblage in Chesuncook Lake. During the call, MDIFW conveyed again that they have a good understanding of the Ripogenus impoundment fish community, and that there are more recent data (e.g., creel angler data and fish stomach content data) that can demonstrate the impoundment supports the indigenous fish assemblage. The following is a brief summary of the discussion with MDIFW during the April 15th conference call:

- MDIFW has a good understanding on species composition in Chesuncook Lake and is comfortable with the information that is available.
- No exotic species are known to occur.
- MDIFW offered to generate a species list from recent and past angler creel data (1,000s of hours of fishing records) that will document indigenous game and non-game species.
- MDIFW may have information from stomach content analysis that could supplement the species list.

On April 25, 2022, MDIFW provided additional data to GLHA consisting of raw data and a summary of data collected from the Ripogenus Impoundment between 1996 and 2021. The data summary provided by MDIFW is provided as an attachment to this letter.

Consistent with the approach that GLHA proposed in the RSP, GLHA will continue to work collaboratively with MDIFW staff to obtain and understand the existing fisheries data available for the Ripogenus impoundment. Additionally, GLHA will process and evaluate the raw data provided by MDIFW and provide a detailed summary of the data in the ISR to demonstrate the current make-up of the fish community.

GLHA's approach to compile and review existing contemporary data and work with MDIFW regional biologists to document that Chesuncook Lake continues to support the indigenous fishery assemblage, along with the proposed macroinvertebrate study in Chesuncook Lake and the aquatic habitat studies at the North Twin and Millinocket Lake impoundments, is a reasonable

and logical approach to determining if the structure and function of the waterbodies in the Project area are maintained.

Existing data from the previous licensing process, more contemporary data (e.g., MDIFW creel data), and professional input from MDIFW biologists will allow GLHA to document that the indigenous species assemblage in Chesuncook Lake is supported without the need for comprehensive, labor-intensive, and costly baseline fish assemblage studies throughout the Project area requested by TU and MDEP.

GLHA also notes that although electrofishing and other netting methods (e.g., seining, trap-netting) are common techniques for sampling shallow, near-shore habitats, it is unlikely that these methods (recommended by MDEP) will capture deep water or pelagic fish species (e.g., lake trout and lake whitefish), so they will only confirm the presence of common, near-shore fish species such as perch, minnows, and fallfish, which are already known to occur.

**April 7, 2022 Letter filed by Maine Council of Trout Unlimited (TU)**

**Comment on Stranding Evaluation Study**

TU submitted study requests for two types of studies: a Ripogenus Flow Excursion Study and a series of Fish Assemblage Studies correlating to the reaches described in the Pre-Application Document. In its Proposed Study Plan (PSP), Brookfield stated the Historical Operations Data and Assessment Study would document any such deviations from project minimums; however, the proposed study did not account for the stranding study component of our requested Flow Excursion Study. Accordingly, TU proposed a Stranding Evaluation Study in its PSP Comments.

**GLHA Response**

GLHA's rationale for not adopting the TU-requested Stranding Evaluation Study is consistent with that provided in the RSP in response to the Ramping Study requested by Mr. Ed Spear. GLHA believes that information collected and reported from other proposed studies, such as the Historical Operations Data Assessment Study, will provide information on how the Ripogenus Project has been operated, including flows provided by McKay Station. Additionally, fieldwork to be performed in the West Branch below McKay Station for other studies will provide additional information regarding flows in the West Branch in relation to aquatic resources.

Concurrent with this filing, GLHA is providing a copy of this letter to all parties listed in the attached distribution list, which can also be downloaded from FERC's eLibrary system at https://www.ferc.gov/docs-filing/elibrary.asp by conducting a search using the docket numbers p-2458 and/or p-2572.

If you have any questions regarding this letter, please contact me by phone at (207) 775-5605 or by email at randy.dorman@brookfieldrenewable.com.

Sincerely,

Randall Dorman
Licensing Manager
Brookfield Renewable

**Summary of MDIFW Species Data from Chesuncook Lake**
**1996 to 2021**

**IFW Clerk Surveys (completed by our staff)**

Winter: We conducted winter clerks surveys in 8 years during the period 1996 – 2021

Summer: We conducted summer clerk surveys in 4 years during the period 1996- 2021

Data summary all years/all seasons:

Total Angler days: 1,821

Total Angler Hours: 10,444

| Species | # Reported (all sizes) |
|---|---|
| Brook Trout | 25 |
| Cusk | 222 |
| Fallfish | 70 |
| Lake Trout | 13 |
| Landlocked Salmon | 2087 |
| Lake Whitefish | 7 |
| Smelt | 390 |
| Splake | 20 |
| White Perch | 300 |
| Yellow Perch | 355 |

**Summary of MDIFW Species Data from Chesuncook Lake**
**1996 to 2021**

**Voluntary record book data**

Winter: We have data from 24 years during the period 1996 – 2021

Summer: We have data from 23 years during the period 1996- 2020

Data summary all years/all seasons:

Total Angler days: 2,777

Total Angler Hours: 15,523

| Species | # Reported (all sizes) |
|---|---|
| Brook Trout | 28 |
| Cusk | 87 |
| Fallfish | 64 |
| Lake Trout | 22 |
| Landlocked Salmon | 6,318 |
| Smelt | 7 |
| Splake | 32 |
| White Perch | 3,474 |
| Yellow Perch | 171 |

MDIFW Age and growth data – These are fish that our staff have handled during creel surveys. They are typically measured, weighed, scale samples and a subsample of stomachs taken.

| Species | # Examined | Mean Length ( mm) | Ages represented |
|---|---|---|---|
| Brook Trout | 4 | 352 | 2-4, 6 |
| Cusk | 17 | 501 | |
| Lake Trout | 7 | 711 | 8,10,17 |
| Landlocked Salmon | 428 | 405 | 3-8 |
| Splake | 19 | 415 | 3-6 |

**Summary of MDIFW Species Data from Chesuncook Lake**
**1996 to 2021**

Food Habits data – Stomach samples are taken during winter clerk surveys. Food items are identified, enumerated, and volumes measured by displacement.

| Species with Stomachs Examined | # examined |
|---|---|
| Brook Trout | 4 |
| Lake Trout | 16 |
| Landlocked Salmon | 376 |
| Splake | 7 |

Food items identified in stomachs

Smelt

Unid. Fish Remains

White Perch

Old Hooks

Insects

White Suckers

Frogs

Unid. Minnow spp

Rocks

Vegetation

**Summary of MDIFW Species Data from Chesuncook Lake**
**1996 to 2021**

**Notes**:

Brook Trout – Population is limited by competition by warm waters species such as white perch, yellow perch, fallfish, and suckers. Brook trout are present in the lake but not abundant. Likely abundant in the tribs.

Cusk: Abundant

Fallfish: Abundant

Lake Trout: Fishery was maintained through a stocking program. Stocking was terminated in 1994.

Landlocked Salmon: Abundant

Lake Whitefish: We are not clear on the status. They do not show up in the winter clerk surveys. If they were abundant, we would expect to see them. Anglers have reported them, but they may be misidentified round whitefish or, most likely, fallfish. The last lake whitefish IFW sampled were in 1970 during a gillnetting operation. Seventeen were taken that ranged in size from 415-520 mm.

Smelt: Present. Although not as abundant as in past years, the population is still considered stable. Anglers that target smelt are successful and smelt are commonly found in salmonid stomachs.

Splake: Splake occasionally drop downstream from Ragged Lake and Deer Pd into the Chesuncook System. Considered incidental.

White Perch: Abundant

Yellow Perch: Abundant

White Sucker: Abundant

RE: Comments on the Revised Study Plans for Ripogenus Hydroelectric Project (FERC No. 2572) and Penobscot Mills Hydroelectric Project (FERC No. 2458) from Kathleen K. Houston

Dear Secretary Bose,

The following comments on the RSP are being submitted after review of the Operations data, in general support of agency study requests with the goal of helping FERC commissioners understand the need for requested studies. Careful analysis of the Operations Data clearly illuminates why agencies and NGO's have requested various studies. The data proves operations are vastly different than under the past licensing and studies are needed to understand the impact of the changes.

**Comments on 1-2 Description of Water Use Plan in relation to Existing Licenses**

The applicant describes: "*current operations are defined by the requirements of the Projects' licenses. Therefore, the 1991 Water Use Plan is not a "management plan" consistent with other management plans resulting from a relicensing proceeding. The one exception being that the Water Use Plan is used as the basis for determining recreational flows from McKay Station at the Ripogenus Project. As indicated in Article 402 of the Ripogenus License*, "*The recreational flow for each month from May through September shall be determined on the first day of each month. This determination shall be based on an analysis of Total Available Water, as described in the Water Use Plan"*

If "recreational flow for each month" is determined on the first day of the month, logic dictates that Recreational Flows during a dry hydrologic year, as defined by the license, would be adhered to. Instead, from June 1, 2020 to September 1, 2020 more water was released than required by the licensee every single day. Most days the release was 500cfs more. Many days the release was as high as 1000 cfs more. The operations data provided does not tell us if the amount of time the excess water was released, but one can assume it was beyond required time parameters as well. The same pattern is seen in 2018 when the lake was two feet down Memorial Day, and more water than required was released every day of the summer but three,

with August 31st finding a lake fourteen feet down. Similar patterns are seen in other years. With this much excess water being released in drought and non-drought years, a logical conclusion is that the fisheries and wildlife are being negatively impacted. Requested studies will help determine the status of aquatic life.

**Comments on 1-3 Description of Mitigation Measures Implemented Pursuant to Existing Licenses**

It must be noted these mitigation measures were required by the past license issued nearly 30 years ago, based on data at that time. It cannot be assumed these mitigation measures have had the intended impact without further study.

The mitigation measures needed in 1996 to "offset impoundment fluctuation" was minimal compared to current impoundment fluctuations. In the 1996 application, the applicant stated, *"Current operations of the Ripogenus impoundment results in annual water level fluctuations of as much as 44 feet. Since 1972, the maximum draw-down during the summer recreation period (between Memorial Day and Labor Day) has been 15.25 feet**: the average has been 3.5 feet (3.10.4.1).**"*

In the last 10 years, **the average drawdown** on Ripogenus, Caribou and Chesuncook lakes on August fifteenth **has been: 8.48 feet**. More than double than at the time of the previous licensing. Maximum drawdowns have been near 20 feet. This vast difference clearly illustrates the difference between the lake environment in the two applications and thus the need for the studies requested by agencies. Following license requirements negotiated before current management of the project does not preclude current, thorough studies.

**Mitigation claims that are unsubstantiated "on the ground"**

Claims conflicting with what is experienced "on the ground" cannot be deemed accurate and thus need further study.

· Claim*: Installation and enhancement of recreation facilities pursuant to the license, for which periodic monitoring was performed (every 6 years through the existing license term) of recreation facility use.*

At the Chesuncook boat landing a kiosk and a bathroom were installed and are well maintained by BPL staff. The boat launch has not been maintained in many years. In 2020, we placed a call to Brookfield requesting the boat launch at Chesuncook Lake be improved as it was unusable by mid-August. The woman we spoke with promised it would be fixed next spring. Nothing was fixed in the spring and the boat launch continued to deteriorate. A Recreational Inventory that also evaluates the quality of launch substrate is necessary.

Claim: *Deployment of artificial nesting platforms for loons and aquatic birds, for which 12 years of monitoring was performed (1998-2010).*

Loon platforms have been found out of water, some broken, along the vast shoreline in different locations and times of year.

**Comments on the Common Loon Management Plan Study**

The Maine Department of Inland Fisheries and Wildlife (MDIFW) recognizes the significance of the loon and formally requested a study to evaluate the Common Loon Management Plan. As the table below illustrates, the applicant's RSP objectives are very different from those of MDIFW.

| **MDIFW Requested Study Objectives** | **GLHA Proposed Study Objectives** |
|---|---|
| *1. **Assess** the use of rafts by loons at the Ripogenus impoundment.* | *1. **Summarize** the results of the loon nesting surveys performed in 1998 and 1999 at the Ripogenus Project* |
| *2. **Evaluate** loon/nesting success under the plan.* | *2.**Summarize** the results of the annual loon nest monitoring surveys performed between 2000 and 2010 at the Ripogenus Project* |
| *3. **Determine** if Project operations, particularly during low water years, are impacting loon nesting success and if new strategies need to be incorporated into the plan."* | *3.**Summarize** specifics as to how the existing loon management plan has been implemented over the term of the existing license* |
| | *4.**Evaluate** the existing information in relation to historic impoundment elevations at the Ripogenus Project* |

The focus of the "objectives" in the applicant's proposal is to "summarize" past data, some of which is over 20 years old. It is concerning summaries, and subsequent analysis and evaluation has not already taken place. How these summaries will meet the requested proposal "to evaluate loon/nesting success," particularly under operating conditions since 2010, is not clear. It is also unclear how "evaluating existing information in relation to impoundment elevations," as proposed, will happen as the summaries are from data before 2010 and the impoundment data shared begins in 2010. The proposed methodology after 2010 is simply to "*summarize the annual procedures from 2011-2021."* There appears to be little connection between the proposed methodology and the requested objective of: "*determine if Project operations, particularly during low water years, are impacting loon nesting success and if new strategies need to be incorporated into the plan."* Please ensure the study objectives from the MDIFW are met, as they are designed to truly evaluate loon success.

The applicant's proposed study plan goals, *"to summarize existing information collected over the term of the existing license related to loons at the Ripogenus impoundment including specific information on how the existing loon management plan has been implemented over time at the Project, which will be used to inform an updated loon management plan **anticipated to be implemented at the Ripogenus Project** over the term of the new license."* are also of concern.

The language "anticipated to be implemented" is alarming. It is imperative a new loon management plan be developed and monitored under the new license. Leaving the door open to not have to do so could be damaging for Maine's iconic loon.

**Comments on 1-4 Recent Hydrology and Effects on Project Conditions**

Claim: *"Although GLHA has implemented water conservation measures at the Projects since the current severe drought conditions began in 2020, including reducing hydro generation at the Ripogenus Project, the current low natural inflows (in combination with the required minimum flows at the Ripogenus Project and the water level and minimum flow requirements at the downstream Penobscot Mills Project) have affected Ripogenus impoundment elevations, particularly during the late spring through fall period*."

Water conservation efforts may have taken place, but these claims fail to acknowledge the impact of water releases beyond license requirements while blaming "*required minimum flows at the Ripogenus Project,*" for impoundment elevations. As previously stated, releasing significantly more water than required by the license every day of the 2020 recreational season, rendering the lake ten feet below full by July 31st, is not water conservation. The data does not give us hourly flows, but we know from the anecdotal data of people living on the river, that there were many nights in the summer of 2020 and 2021 that the river was very high, even raftable, at night. In 2021, the applicant was aware of the drought, and knew the lake was already eight feet down on Memorial Day, yet still released more water than required by the license nearly every day. As a result, at the end of the summer the lake was 17 feet down. Subsequently, GLHA later asked for a minimum flow variation giving full responsibility for this request to the drought or flow requirements downstream.

The past licensee was able to maintain those lake levels without dewatering Chesuncook, Ripogenus and Caribou lakes. The applicant can also control the outflow at downstream bodies of water to meet those lake level requirements. Drought, minimum flow requirements or recreational releases are not the sole cause of extreme lake fluctuations. Excessive water release is a major factor. Every year since 2010 shows a pattern of more water being released than required by the license. In 2010 everyday in August saw releases of over 3500 cfs, when only 1800-2300 is required. As a result, by August 31st, the lake was 13 feet down. It is unfathomable that this does not negatively impact the fish, and entire lake and river ecology. It most certainly negatively impacts recreational use of the lakes. The same is true for 2018 as well as other years. Hourly data would be even more enlightening.

It is as if the applicant considers these "impoundments" commercial wells, in which the faucet can be turned on at will. At most times operations are following the license, which indicates the previous license was developed under vastly different circumstances and the impact must be studied. Power generation must not come at the expense of the fish, the wildlife and the entire ecosystem of the waterways. Agency requested studies are necessary to evaluate the impact of these current operations, which are so very different from those of the past applicant.

The applicant seems to be clinging to the past license and laurels of past project operations, which, as has been repeatedly stated, was issued under a completely different set of economic and environmental circumstances. The paper mill is gone, there are many more camp owners on

the lakes, eco-tourism is the basis of the economy. The great potential of whitewater recreation on the economy of the region must be studied. Millinocket and the surrounding areas need the economic benefit of the recreational opportunities afforded by the lakes and rivers. An economic study, as requested by the Penobscot Nation, would inform a necessary understanding of the socioeconomics of the region, and help ensure current and future economics, as well as non-developmental interests are understood and given balanced consideration in a permit.

Ripogenus dam is no longer being run to provide energy to the mill. It is being run essentially as a peak power plant. A great variation from the 1996 license. Yes, the Ripogenus project provides renewable energy, which is greatly needed. However, the energy produced is not the only source of renewable energy available, and the dewatering of the third largest lake in Maine is too great a casualty. The upcoming license is not a recertification. It is a completely new license and needs the in-depth requested studies to support it.

The local Brookfield representatives understand the dynamics of the lakes and rivers and their importance to the local culture and economy and strive to work with community members. Their efforts are greatly appreciated. Working with them, I firmly believe a balance can be struck that preserves the fisheries and lake quality, provides hydropower, meets the interests of the whitewater community, and stabilizes lake levels for camp owners and recreational users. To achieve this balance, the requested studies need to be completed for a thorough understanding of the socioeconomic, fisheries, wildlife and recreational impacts of current operations so a permit that best balances all stakeholder interests can be achieved.

Thank you for your time and consideration.
Sincerely,

Kathleen K Houston

**RE: Analysis of flow data and Relevant Comments on the Revised Study Plan for the Ripogenus (FERC No. 2572) and Penobscot Mills (FERC No. 2458) Hydroelectric Projects**

Dear Secretary Bose:

On March 23, 2022, Great Lakes Hydro America, LLC (GLHA) filed the Revised Study Plan (RSP) for the Ripogenus Hydroelectric Project (FERC No. 2572-133) Penobscot Mills Hydroelectric Project (FERC No. 2458-247). The RSP contained daily operations data from 2010 to 2021 for each of the projects including impoundment surface elevations and daily discharge for the project's power stations. We note that this data was provided four months after the Federal Energy Regulatory Commission's (FERC) November 28, 2021 deadline for providing this information.

On March 31, 2022, the National Marine Fisheries Service (NMFS) requested that the Commission grant the agencies and stakeholders an additional 60 days to file comments on the revised study plan in order to review 10 years of flow data that was submitted concurrently with GLHP's revised study plan. On April 7, 2022, FERC granted the agencies and stakeholders an additional 21 days to review the flow data and submit comments on the revised study plan (deadline of April 28, 2022).

While we appreciate GLHA providing this data and FERC's extension of time to review this data, in our March 31, 2022 request for flow data we had also requested hourly flow data downstream of each generation facility in the Penobscot Mills and Ripogenus projects. Hourly flow data would allow us to fully understand how each of these projects are being operated on a daily basis, and potentially identify the effects of these operations on aquatic resources. We continue to contend that this data is readily available to GLHA as evidenced by the March 10, 2022, letter to FERC where GLHA submitted hourly flow data at McKay Station for September 7, 2021. Therefore this information should still be provided to fully understand how these projects are being operated. Despite not receiving hourly flow data, we have analyzed several aspects of the data and offer the following observations for FERC's consideration.

Appendix A to this letter provides an analysis of flow profiles (in cubic feet per second (CFS) per square mile to normalize flows/discharge by drainage areas) obtained from the North Branch Penobscot flow gauge compared to the flow profiles through Ripogenus and the Penobscot Mills projects. The North Branch Penobscot is a major, unregulated tributary of the West Branch,

representing a natural flow regime. A run-of-river hydroelectric project in the West Branch would have a flow regime similar to what is observed at the North Branch Penobscot flow gauge. Figure A1 compares the North Branch Penobscot flow profiles to the Ripogenus flow profiles from 2012 - 2021. Figure A2 illustrates 5 years of representative flows through Ripogenus, North Twin, Dolby, and East Millinocket. Figure A3 illustrates 5 years of representative flows through the unregulated portion of the North Branch Penobscot. Together, these data show very consistent, but very different, flow profiles through the unregulated portions of the West Branch compared to the heavily regulated portions of the West Branch. In summary, this analysis reveals that Ripogenus Dam flattens the flow profile and removes most of the discharge variability in the West Branch; this lack of variability is reflected at each of the projects downstream. The loss of flow variability subsequently dampens any disturbance flows, bankfull discharge flows, or channel forming flows that play a crucial role in the health of riverine ecosystems. Riverine organisms and ecosystems, including the feeding, migration, spawning and rearing behaviors of sea-run fish, have evolved around seasonal flow variability that are more synonymous with the flow profile of the North Branch Penobscot. Loss of flow variability puts native species, including sea run fish at a disadvantage to species that are better adapted to stable flow profiles, including invasive smallmouth bass. We expect that FERC will fully consider these effects in its NEPA analysis.

Appendix B to this letter compares project operations with required minimum flows for both recreation and aquatic resources. In their March 9, 2022, letter to FERC, GLHA states that water conservation measures were implemented at the Ripogenus and Penobscot Mills projects due to ongoing drought conditions in the upper Penobscot River watershed. On March 4, 2022, GLHA implemented reduced minimum flows (to 800 cfs at Ripogenus, and to 1,000 cfs at the Millinocket Development, part of the Penobscot Mills Project) to conserve water. However, our analysis of daily project operations data indicate that GLHA was not, in fact, consistently conserving water at the projects from 2019 to 2021 in response to drought conditions. In the figures below, we analyzed flow releases at McKay Station, impoundment elevations at the Ripogenus Project impoundment, and inflows from the North Branch of the Penobscot River. We also chart aquatic and whitewater minimum flows as currently required in the Ripogenus Project license. Taken together, it is obvious that GLHA was generating the McKay power station to provide flows well in excess of the required minimum flows for significant periods throughout 2019, 2020, and 2021 despite low lakes levels in Ripogenus Project impoundment. Neither increased nor reduced generation at McKay Station mirrored inflows from the North Branch of the Penobscot River (USGS No. 01027200 North Branch Penobscot River near Pittston Farm, ME). It would appear that GLHA was conserving water to increase generation at other times of the year. The current mode of operating the Ripogenus and Penobscot Mills Project is certainly impacting fisheries and aquatic resources in the Penobscot River watershed. We urge FERC to consider this information in making a decision to require our requested IHA study for the Ripogenus and Penobscot Mills Project. Note the recreational flows shown in the figures in Appendix B (MIN FLOW: recreation) represent the highest hourly minimum flow requirement for each day of the whitewater rafting period.

**STUDY PLAN RECOMMENDATION**

Specific to this flow data, and based on the limited data that we have received and our analysis of this data, we contend that FERC should require, at a minimum, an Indicators of Hydrological Analysis (IHA) (Study Request 1 in NMFS October 8, 2021 letter) to evaluate the effects of the Penobscot Mills and Ripogenus projects on the hydrology in the West Branch of the Penobscot River, as well as the mainstem Penobscot River downstream to the estuary. Operation of the projects on the West Branch affect the timing and magnitude of flows in the mainstem Penobscot River and may affect the physical and biological features of the Migration Primary Constituent Element of designated critical habitat for the endangered Gulf of Maine distinct population segment of Atlantic salmon (74 FR 29300, June 19, 2009). The results of this study will be used to establish baseline hydrologic conditions, project monitoring and assessment, development and analysis of alternatives for proposed project hydrology, potential mitigation measures, and planning additional instream flow studies as part of this relicensing. The objective of this study is to characterize metrics of hydrologic alteration due to project operational effects and then identify target flows and impoundment levels using the RVA method.

In addition, we are reiterating our request for hourly flow data downstream of each generation facility in the Penobscot Mills and Ripogenus projects. As we have stated previously, all parties to this relicensing must have a precise understanding of the mode of operating the Ripogenus and Penobscot Mills projects to identify potential effects to environmental resources in the project areas.

If you have any questions or need additional information, please contact Dan Kircheis (Dan.Kircheis@noaa.gov) or 207-866-7320.

Sincerely,

Julia E. Crocker

Alexander Kerney, West Boothbay Harbor, ME.
My name is Alex Kerney. I'm a current resident and was born and grew up here, and came back after going to college away. I've been puttering around in boats since I was little, and whitewater kayaking for 15 or so years now, including 5 or so years teaching kids to paddle for the Chewonki Foundation on the West Branch and other rivers around the state and beyond.

These days I send a lot of my free time when I'm not paddling, helping to develop trails and ski glades in the Mahoosucs, and volunteering on a search and rescue team (Mahoosuc Mountain Rescue Team) that has recently added swiftwater rescue to our complement of skills, though I am not representing the team or Chewonki, just myself.

The dryway between Rippogenous Dam and McCay station is a pretty distinct section of whitewater from my experience. While I've tried to paddle it multiple times, I've only gotten a few laps on it as most of the times I've shown up to find the water just having been shut off, so my experiance of the dryway at a range of flows is no where near complete. Because of this, I support American Whitewater's request that on water flow studies are completed on both the dryway and other sections of the West Branch of the Penobscot system.

Cory, Weare, NH.
I lived and worked on the west branch of the Penobscot. In addition to being a kayaker and raft guide on the penobscot , I teach college whitewater kayak courses in the state of Vermont for UVM and NVU. I believe the west branch would benefit tremendously if the were scheduled recreational releases on the millinocket stream a great town run and the Dryway a fantastic expert section  to add to the already quality gorge crib section. This area is a absolutely gold mined of opportunity for teaching whitewater. I have had the opportunity to paddle the Dryway at many different flows from 300,  1000, 1500, 2500, 3000, 6500 cfs and levels in between. This run is very unique for it encompasses a large gorge that was mostly lost in the building of the RIP dam. The Dryway is the last part of the gorge that should be restored. I think these recreational releases are what this area needs to show it’s full potential as a whitewater destination for the people and for the community.

Doug Kranich, Millinocket, ME.
The flow in Millinocket Stream needs to be sufficient for navigating personal watercraft and for fishing. For the past several years, it has been so low that both activities have been compromised. The flow needs to be at a sustainable rate to enjoy this amazing resource within the town of Millinocket. Thank you for listening to my concerns.

Gregory Friel, Millinocket, ME.
Millinocket Lake Dam and Penobscot Mills Relicensing

I would like to comment on the stream flows in Millinocket Stream as part of the relicensing process. I am a Registered Maine Guide, k-12 Outdoor Education Instructor and Physical Education Teacher. Millinocket Stream has been and should continue to be a great resource for the town of Millinocket as well as the local schools. One of my big concerns over the last 5-10 years is a steadily lowering water flow through late spring, summer and fall. It has been impossible to paddle a kayak or canoe down the stream just north of town, through town ending in town at Krandall Park, a gentle paddle and nice fishing trip, normally. I have used this stream for the Outdoor Education Class that I teach at Schenk H.S. for fly casting, canoeing, both swift water in the spring and flat-water paddling and poling inst. in the fall for the past 20 years. We also participate in a partnership paddling project with the University of Maine's Outdoor Leadership Class for a learning experience for our 9-12 Outdoor Education class and our grade 4 students from Opal Myrick Elementary School in East Millinocket. UMaine's Outdoor Leadership Class teaches our students safety and fundamentals of canoeing, a great experience we would love to be able to continue with some kind of consistent flows. The last 5-10 years the flow has lowered to around 80 cfs, not enough to float a boat of any type 150-200 cfs is an awesome and usable level. It would be nice if a usable flow would become the practice that is used to be so the schools and town could take advantage of a great renewable resource and bring it back to what is used to be. Maybe the practice of pumping water across to Ambajejus Lake could be changed to send more water into Millinocket Stream for the sake of recreational and educational opportunities as well as for the wellbeing of the natural resources ( fish, wildlife, plants, ecosystems ect.) Thanks for any consideration you will give to the youth of the Katahdin Region.

Jacob H Risch, Madison, NH.
My Name is Jake Risch, I've grown up spending summers exploring the woods and waters of Northern Maine. As a child, I learned how to paddle a canoe in the headwaters of the East Branch, and later honed my whitewater kayaking and raft guiding skills on the mightly West Branch.

Over the last 25 years, My paddling career has led me to complete whitewater trips and expeditions to 17 countries on four continents, earn a Maine Whitewater Guides license, start a volunteer Swiftwater Rescue Team (the White Mountain Swiftwater Rescue Team), and found a whitewater-based safety and instructional company (Sawyer River Group). Our company currently offers Swftwater Rescue Training on the West Branch.

I'm writing as a business owner with an interest in expanding our offerings in the Millinocket region, as a public safety (swiftwater rescue) expert, and as an avid recreational user of the West Branch Corridor in support of continued recreational flows on the west branch below McCay Station, in support of American Whitewater's comments on flow studies and methodologies for the Dryway section between Rippogenous Gorge and McCay Station, for Millinocket Stream, and for the "Backbend" reach of the west branch near Millinocket.

The West Branch corridor is already a special place for the Maine whitewater community. The addition of these reaches will transform the area into a world-class whitewater destination. Each of the proposed additional scheduled releases add unique characteristics that round out the recreational whitewater offerings of the Millinocket region.

Scheduled releases on Millinocket stream provide an ideal instructional run that will enable reliable beginner and intermediate whitewater courses and swiftwater rescue training sites that are more accessible to town. The backbend section builds the variety of in-town whitewater.

Finally, adding scheduled whitewater releases on the dryway section below Rippogenous Dam to the run below McCay station creates a world-class grade IV/V whitewater run that will incentivize whitewater enthusiasts from around the country (and world) to travel to the region. Those of us who have grown up on the waters of the West Branch appreciate its variety and quality. The one theme I've heard from whitewater boaters from outside of Maine looking for Class IV/V whitewater is that it's a long way to drive for a short section of expert whitewater. A scheduled release on the dryway solves this problem. I predict that this addition could create a draw similar to that of the whitewater releases in upstate NY on the Moose, Raquette, and Beaver rivers. The festivals and races that have emerged as a result of those scheduled releases have become significant economic drivers in similarly rural communities in Northern New York.

Brookfields proposed flow study methodology is not rigorous enough to determine the optimal flows for the diverse user groups that would be drawn to these reaches. A more formal study with an on-water component will provide the data necessary to

maximize the recreational and economic utility of these resources

Joyce P. Smith, MILLINOCKET, ME.
I am commenting on behalf of natural science education. As a local science teacher, I and other science instructors, along with outdoor educational leaders use the local waterways for educational purposes. We use hands-on techniques for instruction in entomology, canoeing, kayaking, fly fishing, and ecosystem sustainability.

When the CFS in our local waterways runs below 150 (as it has been the last few years in Millinocket) we cannot use them for teaching. The learning ceases to exist other than in the form of watching a video or reading an article. The water levels are too low to paddle and are ultimately causing a disturbance to fish and wildlife that is quickly destroying habitats.

Without our children having the opportunity to participate in these activities, we are leaving the future of our ecosystem sustainability to a generation of children who will not understand the importance of preserving the natural way of life that their parents and grandparents hoped to preserve for them.

Jessica Sterling, Bingham, ME.

My name is Jessie Sterling. I've grown up in and around the New England area. A retired runner and sports enthusiast , I've been active all my life. But it wasn't until my late 20s that I found whitewater, or rather it found me. Most people who know me already know this story. I was running a 5k in Portland ME, after which at a craft brew festival I saw an ad for Kennebec Brewing and Whitewater rafting. An odd combination if ever there was one, that was my perspective then so naturally it caught my attention. I ear marked it to look into further.

Not long after I was in a terrible accident that left me wheelchair bound for a short time. After a multi year recovery process that required multiple surgeries, I remain permanently handicap but not incapable. Kayaking became a major contributer to my recovery. The community welcomed me with open arms, they supported me and turned what could have been the worst time in my life into the best. Kayaking brought me back into myself. Whitewater Kayaking made me feel alive and capable of concuring everything. Now in my late 30s, I'm a team paddler for Pyranha Kayaks and Level Six. I compete in steep creek and down river kayak races. I teach beginner to intermediate whitewater kayaking and playback basics. I have kayaked throughout areas of North and South America, but there is no place like home. The West Branch is where I kayaked my first class V rapids, it's where we spend our weekends every summer.

As an instructor I believe, scheduled releases on Millinocket stream provide the opportunity to give beginner and intermediate instruction necessary to reduce entrancw barriers into the sport.
As a paddler and member of the community, adding scheduled whitewater releases on the dryway section below Rippogenous Dam creates a world-class grade IV/V whitewater run that will incentivize whitewater enthusiasts from around the country (and world) to travel to the region. We've seen consist increases in tourism in towns and other areas where they have made changes in support of the whitewater community having reliable flows to kayak on. I encourage you to see the work recently done in Franklin NH, in upstate NY. Allowing consistent access to both of these waterways helps everyone

mary haley, Skowhegan, ME.
Good afternoon,

My name is Mary Haley, I am the CEO of a Skowhegan-based marketing agency with regional coverage of central and Northern, Maine—including the Katahdin and Millinocket area. I am also a Maine Whitewater Guide and private whitewater boater using Brookfield management areas consistently.

My marketing agency specializes in tourism, hospitality, and economic development marketing. We work in rural regions promoting tourism and assets for residents and visitors. We have extensive experience in economic development projects aimed at revitalizing low-income areas.

As I'm sure you are aware, one of Maine's focuses for economic prosperity and revival is tourism and outdoor recreation. Tourism is one of Maine's top revenue generators and provides hundreds of thousands of jobs. Outdoor recreation, specifically, has become a state-wide focus with the creation of the Office of Outdoor Recreation and Maine recently ranked as having the fourth largest outdoor recreation industry in the country.

I am writing in support of continued scheduled releases for whitewater rafting and kayaking from McKay Station. These releases are non-negotiable for the continued existence of one of Millinocket's biggest tourism draws—whitewater rafting and kayaking. The whitewater rafting industry trickles down to benefit all, including, gas stations, hotels, grocery stores, restaurants, Airbnbs, etc. The benefits of this industry is not isolated to direct users only.

In addition to continued releases from McKay Station, I am submitting my support for scheduled releases from Ripogenous Dam for increased use on the Dryway (the gorge above McKay Station) and Millinocket Stream. These releases will increase the area's positioning as an outdoor recreation Mecca, offering more options for river users of all disciplines and skill levels.

I appreciate Brookfield's willingness for a flow study but I would add that the study needs to go beyond an evaluation of current data. Climate change has made our winters more volatile and unpredictable creating conditions that can have harmful implications for commercial outfitters and private users. New and additional data needs to be collected to evaluate these risks properly. A new flow study would also provide the opportunity to reevaluate flows and sections of the river previously deemed unsafe (e.g. the Dryway) or of no value, thus disqualifying those areas from scheduled flows required for use.

Thank you for your time and consideration. I hope my input and expertise provide valuable insight into the FERC process.

Mary Haley
CEO, MXH Marketing

Matthew Melcher, Bingham, ME.
My Name is Matt Melcher, I grew up in Bingham Maine and have been an avid whitewater kayaker for 25 years.
I am writing as an avid recreational user of the West Branch Corridor in support of continued recreational flows on the west branch below McCay Station, in support of American Whitewater's comments on flow studies and methodologies for the Dryway section between Rippogenous Gorge and McCay Station, for Millinocket Stream, and for the “Backbend” reach of the west branch near Millinocket.
The West Branch corridor is already a special place for the Maine whitewater community. The addition of these reaches will transform the area into a world-class whitewater destination. Each of the proposed additional scheduled releases add unique characteristics that round out the recreational whitewater offerings of the Millinocket region.
Scheduled releases on Millinocket stream provide an ideal instructional run that will enable reliable beginner and intermediate runs that are more accessible to town. The backbend section builds the variety of in-town whitewater.
Finally, adding scheduled whitewater releases on the dryway section below Rippogenous Dam to the run below McCay station creates a world-class grade IV/V whitewater run that will incentivize whitewater enthusiasts from around the country (and world) to travel to the region.  Those of us who have grown up on the waters of the West Branch appreciate its variety and quality.  The one theme I’ve heard from whitewater boaters from outside of Maine looking for Class IV/V whitewater is that it's a long way to drive for a short section of expert whitewater.  A scheduled release on the dryway solves this problem. I predict that this addition could create a draw similar to that of the whitewater releases in upstate NY on the Moose, Raquette, and Beaver rivers.  The festivals and races that have emerged as a result of those scheduled releases have become significant economic drivers in similarly rural communities in Northern New York.
Brookfields proposed flow study methodology is not rigorous enough to determine the optimal flows for the diverse user groups that would be drawn to these reaches. A more formal study with an on-water component will provide the data necessary to maximize the recreational and economic utility of these resources

Washington, D.C. 20426

**Via online submission to: http://www/ferc.gov (cross-filed)**

**Subject**: Comments of Maine Professional Rafting Outfitters on the Revised Study Plan for the Ripogenus Project (P-2572) and the Penobscot Mills Project (P-2458)

Dear Secretary Bose:

These comments on the Revised Study Plan (PSP) for the Ripogenus Project (P-2572) and the Penobscot Mills Project (P-2458) filed for Great Lakes Hydro America, LLC by Brookfield Renewable ("Brookfield") are submitted by and on behalf of the members of Maine Professional Rafting Outfitters ("MEPRO"). MEPRO is an unincorporated association of commercial whitewater rafting companies that operate in and around the Penobscot River and all other major rivers in Maine.

Recreation Study

- The study should consider both commercial and public recreation for all licensed areas. In particular, the study should recognize the differences between commercial and non-commercial recreation and the needs of each user group, so these differences can be addressed in any mitigation action taken in the licensing process.
- The study should consider the local communities' renewed reliance on the commercial recreation and tourism industries following the closure of two large, nearby mills. If recreation opportunities in the area were disrupted by the Projects, the local economy would suffer greatly.
- The study should assess recreational facilities in all licensed areas, in order to support proper maintenance or enhancement of these facilities.
- This study should consider wetted width figures based on different flow regimes.
- The study should consider all major tributaries of the Penobscot River, including Millinocket Stream.
- This study should consider minimum and maximum flow based on average conditions, with provisions for hydrologic emergency conditions.
- This study should consider Ripogenus Lake and other impoundments in the system as water storage and reservoir projects, and not as natural lakes.
- Road access to the Project sites for commercial and public recreation must be protected and assured. Furthermore, if Brookfield owns or controls that road access, access should be made available without a fee for commercial and public recreation.

Whitewater Boating Assessment Study

- The study should consider both commercial and non-commercial whitewater boating for all licensed areas. In particular, the study should recognize the differences between commercial and non-commercial whitewater boaters and the needs of each user group, so these differences can be addressed in any mitigation action taken in the licensing process.
- The study should recognize that whitewater boating involves multi-day recreation and should include an assessment of overnight camping areas and the sanitation facilities associated with these camping areas, in order to support proper maintenance or enhancement of these areas and facilities.
- This study should consider minimum and maximum flow based on average conditions, with provisions for hydrologic emergency conditions.
- This study should consider wetted width figures based on different flow regimes.
- This study should consider Ripogenus Lake and other impoundments in the system as water storage and reservoir projects, and not as natural lakes.

Controlled Flow Whitewater Boating and Access Study

- MEPRO supports the Controlled Flow Whitewater Boating and Access Study as proposed by American Whitewater and the Appalachian Mountain Club. This study should consider minimum and maximum flow based on average conditions, with provisions for hydrologic emergency conditions.
- This study should consider Ripogenus Lake and other impoundments in the system as water storage and reservoir projects, and not as natural lakes.
- This study should consider wetted width figures based on different flow regimes.

Water Quality Study

- This study should consider Ripogenus Lake and other impoundments in the system as water storage and reservoir projects, and not as natural lakes.
- This study should consider minimum and maximum flow based on average conditions, with provisions for hydrologic emergency conditions.
- This study should consider wetted width figures based on different flow regimes.

Marsh Bird Survey Study and Furbearer Survey Study

- Both of these studies should consider wetted width figures based on different flow regimes.
- Both of these studies consider Ripogenus Lake and other impoundments in the system as water storage and reservoir projects, and not as natural lakes.

Socioeconomic Study

- MEPRO supports the Socioeconomic Study proposed by the Penobscot Indian Nation. The closure of the remaining paper mills in the area since the last licenses were issued

has changed the local socioeconomic conditions radically, renewing local reliance on the commercial recreation and tourism industries. The Socioeconomic Study is necessary to assess the effects that changing the local commercial recreation conditions through these Projects would have on local communities.

Request for Carbon Sequestration Study

- MEPRO requests a Carbon Sequestration Study to assess the carbon output of mixed or fossil fuel replacement energy in the event the Projects were removed.

Request for Wetted Width Study

- MEPRO requests a Wetted Width Study to assess wetted width figures based on different flow regimes.

MEPRO appreciates the opportunity to comment on these Projects.

Respectfully,

/s/ Joseph Christopher

Robin Nesbeda, ANDOVER, ME.
Maine has a long history of outdoor recreation. Our wilderness/outdoor recreation environments stand-up to better-known (and profitable) areas in other parts of the nation (like the rivers and mountains around Golden, CO). And these activities need not detract from hydro-electric generation. Flow studies can help gather better data for meeting all interests!

One other thought: as a paddler, there need not always be larger releases. More consistent lower-releases can appease paddlers/rafting companies. Consistency matters more than periodic high-volume.

Thank you for your time and consideration!!

Re: The Ripogenus Project P-2572, Great Lakes Hydro America April 27, 2022 Filing; The Licensee's Response to Stakeholder Comments on Revised Study Plan

Great Lakes Hydro America (the Licensee) continues to attack reasonable requests for much needed fish and aquatic communities studies with legal references and data irrelevant to the issues at hand. As in recent filings, the Licensee again misses the point. After the earlier rejection of Maine Department of Inland Fisheries and Wildlife (MeDIFW) creel survey data, is the Licensee actually attempting to tell the Maine Department of Environmental Protection (MDEP) what it needs for information? The MDEP study request is designed to meet statutory goals, (MeDIFW) responsibility is fisheries management rather than determining water quality standard. In its comments in response to the April 7, 2022 letter filed by MDEP "Comment on Fish Assemblage Study", the Licensee in its April 27, 2022 filings, continues its constant refusals to collect meaningful Fish species data as required by the Clean Water Act (CWA).

The Licensee mentions that MeDIFW is the State's lead fisheries agency. This is correct and MeDIFW does an excellent job of managing angler use and harvest. The issue however, is the environment and water quality, salmon are only part of the equation. MDEP has a statutory mandate to determine if all project waters support fish and aquatic communities. The CWA requires this information. This is the responsibility of MDEP and in the absence of useful MeDIFW data they have been forced to ask for a fish assemblage study. The Study result will help MDEP determine if various WQC standards are being met. If project waters are not compliant, and it appears they are not, MDEP has the ability to order operational changes. Possible project operational modifications include lake management and downstream flow requirements. MeDIFW, somewhat "off handily", supported MDEP when they noted Ripogenus drawdown limits and unusually high West Branch flows in its October 8, 2021 filing. Thus, MeDIFW has a stake in the results.

MDEP study results in areas such as juvenile smelt and plankton communities data will provide useful management information to MeDIFW.

The Licensee continues to misuse and misrepresent MeDIFW data. Opinion is not fact. The fact is that MeDIFW has done an excellent effort in its creel survey of the Ripogenus Impoundment landlocked salmon (salmon) population. Another fact is study results are alarming in terms of the Ripogenus Impoundment salmon and rainbow smelt populations. Still, another fact is that MeDIFW creel surveys were not designed to identify the status of non-salmon species e.g. lake whitefish, cusk, smelt, white and yellow perch as any appearance in the "creel" is incidental i.e., not from a directed fishery. Non salmon species are a major concern to MDEP and their meeting of Water Quality Standards. Creel survey data presented by MeDIFW does not meet the objectives of MDEP's study request, namely identifying the status and relative abundance the of all fish species in the Ripogenus Impoundment.

Creel Surveys are a management tool that provide useful information on anglers and catch. However, such surveys do not account for fish species not vulnerable to angling. Creel surveys depend the presence of anglers and the vulnerability of fish species. If the fish are not hungry, they do not bite, thus they are not caught and sampled. Is the licensee suggesting that anglers fish for and catch "minnow" species? No amount of creel survey effort can account for this sampling bias. More robust measures (electrofishing, trap netting, seining, etc.) are required.

In prior filings, MeDIFW has provided conclusive data on the improvise Ripogenus Impoundment salmon population. A population that fails to meet MeDIFW and MDEP standards. The Ripogenus Impoundment adult salmon population (greater than 16 inches) are so in decline that MeDIFW has attempted to increase the harvest of subadult salmon, those less than 16 inches. MeDIFW claims there are too many salmon, I have claimed that the problem(s) lies elsewhere. There are issues with the juvenile smelt and zooplankton populations and the loss of littoral zone production(s). The Proposed MDEP studies will likely provide needed insight.

The Licensee states "MDIFW also noted that the inland fisheries management goals for the Ripogenus impoundment and river have not changed since the last license was approved." This statement is in contradiction with earlier statements. While a MeDIFW goal continues to be salmon management, rules and regulation

for the Ripogenus impoundment have drastically changed. In order to meet what MeDIFW calls an over-population of salmon, the legal size and harvest limits have been changed to encourage the harvest of sub adult salmon, there is NO harvest limit of salmon less than 16 inches. Compared to harvest limits of the late 1980's this a major shift in fisheries management goals. The decline in the salmon fishery coincides with the Licensees change in water management. Coincidence?

The Licensee backs up its refusal to conduct a "Fish Assemblage Study" with information from an April 15, 2022 phone call. *"The following is a brief summary of the discussion with MDIFW during the April 15th conference* call":

- *MDIFW has a good understanding on species composition in Chesuncook Lake and is comfortable with the information that is available.*
- *No exotic species are known to occur.*
- *MDIFW offered to generate a species list from recent and past angler creel data (1,000s of hours of fishing records) that will document indigenous game and non-game species.*
- *MDIFW may have information from stomach content analysis that could supplement the species list.*

Information provided by MeDIFW in the April 15 phone call is simply an update of previously filed reports. No new information is provided. Below, I offer a few remarks on the Licensee's interpretation MeDIFW's comments listed above

1. First, no biologist would characterize a phone call in this manner. It may be true that no new exotic species were evident in creel surveys. It is totally false that NO EXOTIC species occur. Salmon are exotic to the Ripogenus Impoundment as are white and yellow perch and most likely rainbow smelt. How can MeDIFW have an "*understanding on species composition in Chesuncook Lake*" based on biased angler surveys that depend on hungry fish? While MeDIFW creel survey provide useful information on a salmon population in collapse, there have been no trap net, minnow traps, electrofishing, trawling, seining or even gill netting efforts to collect fish species not vulnerable to angling. MeDIFW's understanding of "species composition" inhabiting the Ripogenus Impoundment may be adequate for fisheries management purposes but is totally inadequate in describing

existing the fish communities. Critical fish species information is needed by stakeholders, FERC staff and by MDEP to meet 401 WQC standards and provide corrective measures.

2 I am confident that MeDIFW believes there are no NEW exotic (fish) species. But how can they know with any certainty without the robust sampling proposed by MDEP?

3 The generation of yet another species list will not provide any new data. As noted above, this proposal is biased, as it depends on anglers and then salmon or trout preying on some unknown indigenous or exotic fish species perhaps spatially separated by habitat selection.

4 Salmon are known to depend primarily on rainbow smelt as a forage item. As MeDIFW has demonstrated by its preliminary smelt drift net collection downstream of McKay Station, the Ripogenus Project's juvenile smelt population has collapsed and this has impacted salmon growth in impoundment waters and the downstream West Branch. Thus, MeDIFW's suggestion that salmon stomach content analysis will provide additional information is unlikely, even extreme. The licensee is using a negative to prove a negative.

Even more important, how will FERC staff be informed of the status of lake whitefish (Coregonus clupeaformis) and smelt population? Diminished lake whitefish populations are currently a major MeDIFW concern. As noted above, juvenile smelt population in the Ripogenus Impoundment have declined to the point where they no longer provide a salmon food source in the West Branch downstream of McKay Station. These two important species of MeDIFW management concern must be sampled. Nothing reported in the April 15, 2022 conference call deals with these important fish species. The below is an abbreviated summary demonstrating the importance of lake whitefish to fisheries management as documented in the Vol I of the 2021 plan, Managing Maine's Inland Fisheries into the Future.

*Lake Whitefish: Goals, Objectives & Conservation/Management Strategies*

*Goal; Conserve native populations of lake whitefish Assess the status and health of all known populations of lake whitefish in Maine (High Priority)*

*• Develop an assessment plan to characterize population age structure and relative abundance to establish a baseline for this planning period.*

*Identify and implement strategies to reduce threats and protect lake whitefish (High Priority)*

*• Examine Department stocking and management programs to reduce potential impacts to lake whitefish populations, considerate of inter-specific competition, regulations, lake whitefish population abundance, angler use, and risk for new competing introduction.*

*Monitor lake whitefish populations (High Priority)*

*• Develop a long-term population monitoring program to assess changes in population size and age structure*
*• Identify habitats (e.g., spawning) where lake whitefish are more vulnerable to sampling*

*Monitor lake whitefish populations (High Priority)*

*• Develop a long-term population monitoring program to assess changes in population size and age structure*
*• Identify habitats (e.g., spawning) where lake whitefish are more vulnerable to sampling*

Clearly MeDIFW has a departmental mandate to accept or participate in a Ripogenus Impoundment fish assemblage study. Study results can only enhance fisheries management objectives, including and perhaps most importantly, lake whitefish. The 1992 License application documented a concentration of lake whitefish at the mouth of Umbazookus Stream. The only downside to fish assemblage studies is that it will confirm the Licensee's worse fears; project operations are degrading Ripogenus fish communities.

The Licensee is obviously concerned that updated 2022 data will weaken their arguments that "nothing has changed, everything is Ok". The Licensee's April 27, 2022 filing is simply another "data dump" coupled with legal arguments, no new fisheries data were provided. The apparent premise is that if they say "nothing has changed" enough, people will begin to believe them. Quote case law often

and perhaps the stakeholders and agencies will back away. Hopefully FERC staff will require the needed studies as this information will be needed when negotiations begin.

Re: The Ripogenus Projects P-2572

Great Lakes Hydro America's April 29, 2022 Filing, Articles 402 and 406: Violations not Excursions?

The Licensee's April 29, 2022 filing calls the past winter's low flow event an "excursion" when it was, in fact, a violation of two License Articles; 402 and 406. Extreme low fall and winter flows impacted two salmon year class (fry from 2020 and eggs from 2021 spawning) and aquatic communities. The impact of lost salmon reproduction will be evident in two to four years.

The licensee's April 29, 2022 "after the fact" *salmon spawning and incubation minimum flow excursion* Article 402 notification is not only six months late but additionally, fails to acknowledge the obvious violation of Article 406 of the Ripogenus Project License. Low McKay Station flow events that began September 6, of 2021 (GHHA filing of March 23, 2022) and continued into April, 18 2022. This impacted juvenile landlocked salmon (salmon) habitat in all areas downstream of McKay Station. Article 406 was designed as mitigation. The goal was to produce young-of-the-year salmon in the Holbrook spawning and nursey bypass channel. Article 406 requires a flow of 35 cfs for the period beginning June 1, continuing until October 15. At that time flows are increased to 65 cfs. On September 17, 2021 the licensee photographed the upper section of the Holbrook bypass area. These pictures clearly show a reach with low flow and unsuited to meet goals developed by MeDIFW. This was the first documented violation of Article 406. Flows were further reduced March 4, 2022 (March 9, 2022 filing). The result was the additional loss of salmon fry and parr overwintering in the bypass and downstream reaches. This was in addition to spawning and incubation losses admitted to by the Licensee in its April 29, 2002 filing. In summary, poor flow management resulted in a serious and avoidable violation of Article 406 and the loss of two years classes of salmon; winter kill of fry spawned in 2020 and spawning failure in the fall of 2021

FERC's licensing and compliance process is based on trust. Licensees are <u>required</u> to follow conditions <u>imposed</u> to mitigate private use of a public resource. In this framework the licensee is <u>mandated</u> to self-report any failure, for whatever reason, to comply with the term of its license. As several filings by interested parties in the on-going relicensing have shown, Brookfield does not understand the rules, or worse is willfully ignoring them.

The Licensee wants the public and FERC staff to believe that it had no idea it was required to provide water to the Holbrook by-pass. They simply maintained a pattern of providing water and when it dried up the fish eggs and other habitat for six months it was an excursion from that pattern. A violation for which they show no remorse.

In my opinion, FERC must impose a civil penalty of at least modest proportion, to demonstrate to this licensee that compliance and trust must be introduced to its corporate hydroelectric operations.

Thank you for the opportunity to comment.

TROUT UNLIMITED
MAINE COUNCIL

**Via online submission to: http://www/ferc.gov (cross-filed)**

Subject: **Maine Council of Trout Unlimited Comments on the Minimum Flow Excursion Report dated April 28, 2022 for the Ripogenus Project (P-2572)**

Dear Secretary Bose:

On behalf of its six chapters and over 2,000 members, Maine Council of Trout Unlimited ("TU)" submits these comments on the Minimum Flow Excursion Report for the Ripogenus Project (P-2572) submitted by GLHA ("Brookfield" or "Operator") dated April 28, 2022. The event report was assigned sub-docket P-2572-136.

**The event**

Quoted from the report that is included for FERC staff convenience as Attachment A:

"*DESCRIPTION: Through agency consultation, a target flow of 1,100 cfs was established for the West Branch of the Penobscot River below McKay Station for the October 15 – November 15, 2021 spawning period. This 1,100 cfs target flow was then released from McKay Station from November 16, 2021 to March 4, 2022 for salmon egg incubation. On March 4th, the target flow was further reduced to 800 cfs through agency consultation; the 800 cfs target flow was then maintained until April 18, 2022, at which time increased and normal flows were resumed."*

"*OBSERVED OR REPORTED EFFECTS: Although the Maine Department of Inland Fisheries and Wildlife expressed concern that the reduced flows could affect salmonid redds, GLHA is not aware of any specific impacts to fish and wildlife resources, dam safety, or public safety resulting from this event*."

"*RESOURCE AGENCY COMMENTS: The Maine Departments of Inland Fisheries and Wildlife and Environmental Protection had questions and expressed concern with the reduced flows, but both supported the flow reductions (along with the Maine Land Use Planning Commission and the United States Fish and Wildlife Service) once they received additional information and better understood the drought conditions in the watershed and GLHA's water management actions in response to these conditions.*"[1]

[1] Minimum Flow Excursion Report for the Ripogenus Project (P-2572) dated April 28, 2022.

**Context**

The purpose of these comments is to provide context to the Brookfield Minimum Flow Excursion Report.

The existing license states: "*Minimum flows may be modified if required by hydrologic conditions beyond the control of the licensee, upon mutual agreement between the licensee, the U.S. Fish and Wildlife Service, DEP, LURC, and DIFW. If the flow is so modified, the licensee shall notify the Commission as soon as possible, but no later than 10 days after each such incident."*[2] As Mr. Ed Spear pointed out in his March 9 filing included as Attachment B: "*The key component of the above Article is: hydrologic conditions beyond the control of the licensee*."[3] Brookfield contributed to the hydrological conditions by releasing far more water than licensed minimum flow requirements that would not have exceeded 2300 cfs regardless if the operator considered the year a normal or a dry one. This fact was documented and described by the filing made by Ms. Kathleen Houston on March 13, 2022. This table is the most pertinent. The filing is included as Attachment C[4]

**AS OF SAT AUGUST 14 11:41AM EDT**

Total Flow 3100 cfs

**SHORT-TERM SCHEDULE**

| START DATE | START TIME | END DATE | END TIME | CFS |
|---|---|---|---|---|
| 8/11/2021 | 8:00 AM | 8/11/2021 | 9:00 PM | 3,000 |
| | 9:00 PM | 8/12/2021 | 8:00 AM | 1,800 |
| 8/12/2021 | 8:00 AM | 8/12/2021 | 5:00 PM | 2,200 |
| | 5:00 PM | 8/12/2021 | 9:00 PM | 3,400 |
| | 9:00 PM | 8/13/2021 | 8:00 AM | 1,800 |
| 8/13/2021 | 8:00 AM | 8/13/2021 | 12:00 PM | 2,000 |
| | 12:00 PM | 8/13/2021 | 5:00 PM | 3,000 |
| | 5:00 PM | 8/13/2021 | 9:00 PM | 3,400 |
| | 9:00 PM | 8/14/2021 | 8:00 AM | 1,800 |

**Minimum Flow Requirements downstream of McKay Station for the Ripogenus Project[1]**

| Date Range | Minimum Flow Requirement |
|---|---|
| ***Fish Spawning or Incubation*** | |
| September 16 – October 14 | 1,000 cfs to facilitate drawdown of the North Twin impoundment (part of the Penobscot Mills Project) |
| October 15 – November 15 | At least 1,422 cfs or inflow, but not less than 1,300 cfs[2] for salmon spawning |
| November 16 – June 7 | Greater than 1,422 cfs (or the spawning flow established above for the year)[2] for salmon incubation |
| ***Whitewater*** | |
| May 1 – September 15 (8:30 AM – 5:00 PM) | Normal hydrologic year[3]:<br>• 2,300 cfs on Saturdays and Sundays<br>• 2,200 cfs on Mondays and Fridays<br>• 2,000 cfs on Tuesdays through Thursdays<br>Wet or dry hydrologic year[3]:<br>• 2,200 cfs on Saturdays and Sundays<br>• 2,000 cfs on Mondays and Fridays<br>• 1,800 cfs on Tuesdays through Thursdays |
| September 16 – October 1 (8:30 AM – 5:00 PM) | Normal hydrologic year[3]:<br>• 2,300 cfs on Saturdays and Sundays<br>Wet or dry hydrologic year[3]:<br>• 2,200 cfs on Saturdays and Sundays |
| June 8 – October 14 (5:00 PM – 8:30 AM) | 1,000 cfs |
| ***Station Outages*** | |
| Times of generating unit outage | 400 cfs with scheduled minimum flows identified above in table to be resumed as quickly as possible by releases from Ripogenus Dam if necessary but in no event in more than three days following the initial outage |

[1] Minimum flows shall be the minimum flows for each hourly period measured on the basis of an hourly average.
[2] Flows to be established each year in consultation with the USFWS and MDIFW.
[3] The whitewater flow for each month from May through September is determined on the first day of each month based on an analysis of Total Available Water as described in the Water Use Plan in the application for new license filed with the Commission on December 17, 1991. The determination of "wet," "normal," or "dry" shall remain constant during the month based on the first day of the month classification. The range of "normal" available water

**FERC should determine that the low flow event constitutes a license violation**

The Operator can't have it both ways: claim that operations below minimum flows were caused by a dry year while operating far in excess of the minimums only a couple of months before. Brookfield has owned the project for over ten years, so inexperience cannot be to blame.

**Other license violations continue to occur**

Brookfield holds that: "*Based on a review of the Projects' compliance history, GLHA has been and continues to be in compliance with the applicable Articles of the existing FERC Licenses, or have been otherwise communicated to FERC and the applicable resource agencies and addressed by GLHA*."[6] This claim is unsupported by the facts. Mr. Spear detailed additional matters that TU askes the Commission to consider as possible violations of the licenses for both the Ripogenus and the Penobscot Mills projects license provisions. These include:

[6] Id., page 4-66.

"*Article 402 – Ripogenus Project, Upper Gorge July-September 30 flows*

*Article 406 - Ripogenus Project, Holbrook Bypass Channel Salmon Spawning and Nursery Flows*

*Article 408 – Penobscot Mills Project, Irregular Flows*

*Article 413 -Millinocket Stream, Spring and Fall Brook Trout Stockings*"[7]

The filing also references the Use of the Water Management Plan: "*The Licensee has mostly ignored the 1996 Water Management Plan (WMP) and arbitrarily set up its own water management plan; a peaking operation driven by the market for electric power that conflicts with environmental needs."*[8] We have included this filing as Attachment D.

Brookfield has also stated that the PM&E Measures included in the current license are adequate: "*These PM&E measures comprehensively address resource interests specific to the Project areas, as well as the larger river basin. These interests include water quality; management and balancing of flows within and downstream of the West Branch; aquatic and terrestrial resources; whitewater and recreational opportunities; cultural resources; and land management."*[9] If this is so, then at least some of the cause of the problems previously described with Ripogenus-Chesuncook impoundment levels must be ascribed to the operator.

**Current license minimum flows are overly permissive**

Please note some of the numbers that define minimum flows under different conditions, especially 400 cfs and 100 cfs. They were not based on biotic studies; 400 cfs is the flow through the turbines with brakes applied when a generator trip occurs, 1000 cfs is the low end of effective single generator operation. 1422 cfs was determined from the median flows determined by catchment hydrography and is not supported by study data that sought to determine optimal or minimum flows for aquatic life. Mr. Spear reports that the 1000 cfs flow did not provide adequate watering of the Holbrook bypass designed to provide additional salmonid spawning and nursery habitat: "*On September 14, 2021 Licensee's staff photographed the upper Bypass Channel at a reported station flow of 1000 cfs (see the Licensee's September 30, 2021 filing). The two pictures show a flow that lacks surface turbulence and riffles, conditions needed for optimum YOY salmon production. Looking downstream from the intake gates, a long, flat stretch with an 'unbroken' surface is apparent. Such waters are not suitable for YOY salmon and salmon production is lost or reduced under a 1000 cfs flow regime*."[10] Flows were subsequently reduced to 800 cfs for nearly two months so fisheries impacts were bound to have occurred. "*The Maine Departments of Inland Fisheries and Wildlife and Environmental Protection had questions and expressed concern with the reduced flows*"[11] but did not have specific flow limits developed by scientific study upon which to base stronger objections. TU has documented that 400 cfs

[7] Ed Spear letter dated April 27, 2022, RE: Re: The Ripogenus and Penobscot Mills Projects P-2572 and P-2458 Great Lakes Hydro America's failure to meet 401 Water Quality Certification Articles and Protection, Migration and Enhancements Measures during 2021.
[8] Id., page 6.
[9] Ripogenus Project PAD, page 1-8.
[10] Ed Spear letter of April 27, 2022. Page 4
[11] Minimum Flow Excursion Report for the Ripogenus Project (P-2572) dated April 28, 2022.

results in strandings;[12] this minimum flow must be considered extremely permissive as flows low enough to cause major dewatering and stranding do not constitute license violations; there are no limits specified in the license as to how low the Ripogenus-Chesuncook Impoundment can be drawn down, the dewatering and profound effects on both the aquatic life and recreational opportunities are so well documented on the FERC docket that we see no need to repeat them in this filing. The reason for this is clear. Look at the filings on the FERC docket from the last relicensing, they include comments from a number of prominent politicians. At one point during 1993, three comments in a row were from state legislators: Accession numbers 19930915-0188, 19930915-0190, and 19930915-0191. Maximum political pressure was put on both FERC and the Maine Department of Environmental Protection.

**The Operator is providing the minimum flow data possible**

The FERC response to the report of strandings and other possible license violations described in the previous paragraph included the recommendation that Brookfield work with TU and look into strandings.[13] That has yet to happen as we explained in our PSP Comments[14] that we have not attached due to their size, accession number is provided. NOAA fisheries requested ten years of hourly operational data from the projects and reiterated their request in their Proposed Study Plan Comments because Brookfield had not provided it. As TU had noted in its prior filing,[15] Brookfield has had the data all along at least at one-minute granularity. The data Brookfield has provided was lake levels, and flows daily: minimum, maximum, and average. Given that the license minimum flows may vary hourly during summer months, this level of detail obscures possible license violations. Brookfield has continued to reject conducting stranding or ramping studies as detailed in its eleventh hour Proposed Study Plan filing[16] provided as Attachment F. All Brookfield does is to repeat previous references to Mr. Spear's Ramping study that it also rejects in favor of its Historical Operations Data Assessment Study which looks at historical data without regard for the effects of rapid cessations of flows resulting in the strandings that we have previously mentioned. Of additional note is that all of Brookfield's filings have included the notation "*Copyright © 2021, Great Lakes Hydro America, LLC. All rights reserved*." Once filed, the information contained therein became part of the public domain. We question why Brookfield sees such a need for secrecy during the study phase of relicensing designed to inform the relicensing process and wonder what Brookfield needs to hide.

**The Operator's problems managing flows at McKay Station go back to soon after assuming control of the Ripogenus Project**

Taking a longer view, Brookfield's contention that it "*has been and continues to be in compliance with the applicable Articles of the existing FERC Licenses"* becomes even weaker. Brookfield committed a license violation shortly after assuming control of Ripogenus operations by failing to provide the 100

[12] TU Letter dated January 5, 2022. Subject: Maine Council of Trout Unlimited Amplifying Report for Observed Low Flow Events for the Ripogenus Project (P-2572).

[13] FERC letter dated March 1, 2022. Page 3: *"…we encourage you to work with Trout Unlimited, the resource agencies, and Commission staff to develop a proposal to address strandings and include it in the final license application you file by September 30, 2024. In the meantime, we also encourage you to conduct aquatic habitat surveys immediately following any future unit outages, if time allows prior to restoration of flows*."

[14] TU RSP Comments dated April 7, 2022. Accession number 20220407-5187, page 4.

[15] Id, page 2.

[16] Brookfield letter of April 27, 2022, Subject: Ripogenus Hydroelectric Project (FERC No. 2572-133), Penobscot Mills Hydroelectric Project (FERC No. 2458-247), Response to Stakeholder Comments on Revised Study Plan, page 7.

cfs fishing flow required from July 1 to September 30 yearly.[17] We have included the FERC determination[18] as Attachment G. More recently and significantly, Brookfield apparently let the braking systems that ensures the 400 cfs generator trip flows to deteriorate by 2015. This caused an outage that lasted for days and necessitated deep gate releases to provide minimum flows. We have included an applicable filing for that incident as well as Attachment H.[19]

The NGOs involved with this relicensing are on record that: "*To date, any reasonable analysis of Brookfield's participation in the Ripogenus - Penobscot Mills relicensing process indicates that Brookfield is attempting to delay and confuse the process by failing to provide the data required by FERC with the PAD, and then rejecting study requests involving the data*."[20] We have attached that filing as well as Attachment I. Taken as a whole, the record is clear that Brookfield is being less than forthcoming with the Commission. Brookfield rejects both the stranding and ramping studies explaining that the Historical Operations Data Assessment Study "*will provide information on how the Ripogenus Project has been operated, including flows provided by McKay Station.*"[21] This plan is so vague that it can select data electively and provides no assurance that it would do other than demonstrate that Brookfield has been in compliance with the lax terms and conditions of its license most of the time: "*GLHA will present the operations data in relation to the applicable license requirements for the Projects.*"[22] We have attached the study plan as Attachment J. Given what has transpired since Brookfield purchased GLHA, should FERC accept this study in its Study Plan Determination and should it be accomplished, the commission should examine its contents with the utmost scrutiny and not use it as a basis for its Compliance Report required for the final licensing stage of the process.

We ask that when investigating the matters we have described above that Brookfield look further than just the events reported above and examine the flows occurring during the timeframe from August 1, 2021 and the present. If violations are found to have occurred then we ask that the window of scrutiny be expanded so that the extent of violations can be fully determined. If Brookfield has been guilty of multiple license violations, then they should be considered matters in aggravation when determining if FERC should take enforcement action.

[17] Ripogenus PAD, page 4-43: "*Pursuant to Article 401 of the existing license, a minimum flow of 100 cfs is released from Ripogenus Dam into the bypassed reach (Upper Gorge) from July 1 through September 30 annually.*"

[18]

[19] Brookfield letter dated January 7, 2016, RE: Ripogenus Project 2572, Article 402 Compliance; Follow-up to June 13, 2015 Flow Excursion due to McKay Station Outage

[20] Preliminary Comments on the Proposed Study Plan (PSP) for the Ripogenus Project (P-2572) and the Penobscot Mills Project (P-2458), page 4.

[21] Brookfield letter of April 27, 2022, Subject: Ripogenus Hydroelectric Project (FERC No. 2572-133), Penobscot Mills Hydroelectric Project (FERC No. 2458-247), Response to Stakeholder Comments on Revised Study Plan, page 7.

[22] RSP, Pages J-1 through J-3, Historical Operations Data Assessment Study Plan.

**Enforcement action should be seriously considered by the Commission**

FERC has taken a more aggressive stance on enforcement actions since the dam failures in Michigan that occurred in 2019,[23] most recently Ampersand Cranberry Lake Hydro LLC[24] that seems to TU to be less impactful than the recent events involving the Ripogenus Project. These events prompted the letter filed by Mr. Spear that recommends enforcement action that we have included as Attachment J. Should FERC decide that enforcement action is warranted, we propose that rather than a fine, Brookfield should be required to install and maintain a USGS gage at some location between McKay Station and Telos Bridge to be determined by USGS. FERC Compliance would be saved needless effort and delay obtaining data from the Operator if those impacted by the low flows not constituting license violations had ready access to flow data readily available on the USGS National Water Information System: Web Interface.

**Conclusion with Requests**

Maine TU Council appreciates the Commission's continuing attention to compliance issues involving the Ripogenus and Penobscot Mills Projects. Compliance history is a factor to be considered during the final licensing phase and we trust that the information contained in this filing will prove useful then as well as now.

We ask that the Commission investigate the matter contained in this letter for possible license violations, and if new violations are found, expand the scope of their investigation.

Should FERC decide that enforcement action is warranted, we propose that Brookfield be required to install a USGS compatible flow gage between McKay Station and Telos Bridge at Brookfield expense and be maintained at their expense for the next ten years. We think that this would not only be appropriate but would also serve to prevent stakeholders filing low flow reports with FERC and necessitating investigations where if a USGS gage were present, no report would need to be filed.

We additionally note that if FERC obtains additional operational data reported hourly or by the minute, that this be made part of the public record and appear on the applicable FERC dockets.

TU reiterates its request for a copy of the Brookfield Renewable 11th Part 12D Independent Consultant's Safety Inspection Report and associated Potential Failure Mode Analysis Addendum for the Ripogenus Project under P-2572, Accession Number 20211229-5198, especially the addendum as previously requested.[25]

**Subject: Ripogenus Project (FERC No. 2572-ME); Minimum Flow Excursion**

Dear Secretary Bose:

As follow-up to an update provided to the Commission on March 9, 2022, Great Lakes Hydro America, LLC (GLHA), licensee for the Ripogenus Project, is reporting a salmon spawning and incubation minimum flow excursion that occurred at the Project's McKay Station from October 15, 2021 to April 18, 2022.

Please see the attached excursion reporting form for details.

If you have any questions, please contact me by phone at (207) 951-5006 or by e-mail at kevin.bernier@brookfieldrenewable.com.

Sincerely,

Kevin Bernier

| Brookfield | | | COMPLIANCE EXCURSION REPORT | | |
|---|---|---|---|---|---|
| **Project No(s):** | FERC No. 2572-ME | | **Project Name(s):** | Ripogenus Project | |
| **Licensee(s):** | Great Lakes Hydro America, LLC (GLHA) | | **Facility:** | McKay Station | |
| **SUBJECT:** | Minimum Flow Excursion | | | | |
| **BACKGROUND** (e.g. License Article/ Requirement; Permit Condition; Operating Procedure, etc.): | Article 402 of the Ripogenus Project license states in relevant part that, "The licensee shall release from the Ripogenus Project into the West Branch of the Penobscot River below McKay Station the following minimum flows: Salmon spawning flows of at least 1,422 cfs or inflow, but not less than 1,300 cfs, from October 15 to November 15, and salmon incubation flows greater than 1422 cfs (or the spawning flow established for that year) from November 16 through June 7. These flows shall be established each year in consultation with the U.S. Fish and Wildlife Service and Maine Department of Inland Fisheries and Wildlife." | | | | |
| **DATE OF EVENT:** | 10/15/21 – 4/18/22 | **TIME OF EVENT:** | N/A | **DURATION:** | 185 days |
| **DESCRIPTION:** | Through agency consultation, a target flow of 1,100 cfs was established for the West Branch of the Penobscot River below McKay Station for the October 15 – November 15, 2021 spawning period. This 1,100 cfs target flow was then released from McKay Station from November 16, 2021 to March 4, 2022 for salmon egg incubation. On March 4th, the target flow was further reduced to 800 cfs through agency consultation; the 800 cfs target flow was then maintained until April 18, 2022, at which time increased and normal flows were resumed. | | | | |
| **CAUSE:** | Salmon spawning and incubation flows were reduced due to severe drought conditions in the Upper Penobscot drainage. | | | | |
| **CORRECTIVE MEASURES:** | **IMMEDIATE ACTION** | Reduced salmon spawning and incubation flows were implemented on October 15, 2021, and then further reduced on March 4, 2022, in order to conserve water in response to severe drought conditions. | | | |
| | **LONG-TERM ACTION** | None – the reduced flows were beyond GLHA's control. | | | |
| **OBSERVED OR REPORTED EFFECTS:** | Although the Maine Department of Inland Fisheries and Wildlife expressed concern that the reduced flows could affect salmonid redds, GLHA is not aware of any specific impacts to fish and wildlife resources, dam safety, or public safety resulting from this event. | | | | |
| **AGENCIES NOTIFIED** (attach correspondence): | **Method of Initial Notification:** ☐ Phone x Email ☐ Letter **Date of Notification**: multiple (attached)<br>**Federal Agencies**: x USFWS ☐ NMFS ☐ USACE x FERC ☐ Other(s): _____<br>**State Agencies:** STATE: Maine x Env. Prot x F&W ☐ Dam Safety ☐ Other(s) Land Use Planning<br>**Other Agencies/NGOs**: None | | | | |
| **RESOURCE AGENCY COMMENTS:** | The Maine Departments of Inland Fisheries and Wildlife and Environmental Protection had questions and expressed concern with the reduced flows, but both supported the flow reductions (along with the Maine Land Use Planning Commission and the United States Fish and Wildlife Service) once they received additional information and better understood the drought conditions in the watershed and GLHA's water management actions in response to these conditions. | | | | |
| **ADDITIONAL INFORMATION /COMMENTS:** | None | | | | |

| **Subject:** | West Branch 2021 salmon spawning flow, Ripogenus Project |
| **Date:** | Monday, October 4, 2021 8:50:00 PM |
| **Attachments:** | image001.jpg |

As required by Article 402 of the Ripogenus Project FERC License, Great Lakes Hydro America, LLC (GLHA) must provide the following flows to the West Branch of the Penobscot River below McKay Station:

> *"salmon spawning flows of at least 1,422 cfs or inflow, but not less than 1,300 cfs, from October 15 to November 15 and salmon incubation flows greater than 1,422 cfs (or the spawning flow established above for that year) from November 16 through June 7. These flows shall be established each year in consultation with the U.S. Fish and Wildlife Service and Maine Department of Inland Fisheries and Wildlife*."

However, the Ripogenus FERC license also allows this minimum flow to be modified if required by hydrologic conditions, specifically:

> "*Minimum flows may be modified if required by hydrologic conditions beyond the control of the licensee, upon mutual agreement between the licensee, the U.S. Fish and Wildlife Service, DEP, LURC, and DIFW*".

Due to the current low Ripogenus impoundment level that has resulted from this year's drought (down over 21 feet from full pond this morning), GLHA is proposing to set 1,100 cfs as the 2021 target spawning flow for McKay Station for the October 15 to November 15 period. This spawning flow needs to be low enough so that subsequent egg incubation flows can be maintained throughout the winter that are at least as high as the spawning flow; thus, GLHA needs to set the spawning flow as low as possible to ensure that these incubation flows can be provided, given the limited water storage currently available upstream. Inflows into the Ripogenus impoundment are currently running at about 930 cfs, so even under this reduced spawning flow, the Ripogenus impoundment will continue to drop until the upper Penobscot drainage gets some rain.

Please provide any comments or questions on this proposed spawning flow by Wednesday, October 13th, and note that I'll assume your concurrence with the proposed 1,100 cfs spawning flow if I don't hear from you. Thank you.

| **Subject:** | Minimum flow reduction proposals for Ripogenus and Millinocket |
| **Date:** | Wednesday, February 23, 2022 1:29:00 PM |
| **Attachments:** | image001.jpg |

Due to the ongoing severe drought conditions in portions of the upper Penobscot watershed (see Maine | Drought.gov for current and historic drought conditions in Maine), Great Lakes Hydro America, LLC (GLHA), licensee for the Storage (FERC No. 2634), Ripogenus (FERC No. 2572), and Penobscot Mills (FERC No. 2458) Projects, has been implementing water conservation measures on the Upper Penobscot since the current drought intensified beginning in 2020. Due to impoundment levels and snowpack water content that are both running well below average, GLHA is proposing to reduce minimum flows further (to 800 cfs at Ripogenus, and 1,000 cfs at Millinocket) as was done during the 2001 – 2003 severe drought. Recent snow surveys in the upper Penobscot drainage have shown average water content in the snow to be about 20% below the long-term average. In addition, water levels are currently much lower than normal in both the Ripogenus (over 24 feet below full pond) and North Twin (almost 8 feet below full pond) impoundments.

Article 402 of the Ripogenus Project license states in relevant part that, "*The licensee shall release from the Ripogenus Project into the West Branch of the Penobscot River below McKay Station the following minimum flows: Salmon spawning flows of at least 1,422 cfs or inflow, but not less than 1,300 cfs, from October 15 to November 15, and salmon incubation flows greater than 1422 cfs (or the spawning flow established for that year) from November 16 through June 7.*" As indicated in GLHA's October 4, 2021 e-mail (see below), last fall's spawning and incubation flow was set at only 1,100 cfs due to the drought and low water level conditions. However, the Ripogenus impoundment has continued to drop despite this flow reduction. Article 402 of the Ripogenus Project license also allows GLHA to modify the minimum flows from McKay station if required by hydrologic conditions beyond GLHA's control. Such flow modifications must be mutually agreed upon between GLHA, the U.S. Fish and Wildlife Service (F&WS), the Maine Department of Inland Fisheries and Wildlife (IF&W), the Maine Department of Environmental Protection (DEP), and the Maine Land Use Regulation Commission (now the Land Use Planning Commission - LUPC). GLHA must then notify FERC within 10 days of the event.

Article 403 of the Penobscot Mills license states in part that, "*The licensee shall operate the Millinocket, Dolby, and East Millinocket developments in a run-of-river mode while providing an instantaneous minimum flow of 2,000 cubic feet per second (cfs) to the West Branch of the Penobscot River at Millinocket, for the protection of water quality and aquatic habitat in the Penobscot River.*" Article 402 also allows run-of-river operation or minimum flows to be temporarily modified if required by operating emergencies beyond the control of the licensee, and for short periods upon mutual agreement between the licensee, the U.S. Fish and Wildlife Service, and the Maine DEP. GLHA must then notify FERC within 10 days after the event.

As indicated above, GLHA requests agency concurrence for minimum flow reductions at both Ripogenus (to 800 cfs from the current 1,100 cfs) and at Millinocket (to 1,000 cfs from the current

2,000 cfs) due to the continued drought and low water level conditions. Please respond to this proposal **by the end of this week**, as GLHA intends to implement these flow reductions early next week. Thank you.

Good morning Kevin,

The staff at the Land Use Planning Commission finds that there would be no undue adverse effect by reducing the minimum flow at either Ripogenus or Millinocket.

Thanks,

Ruby

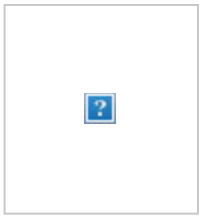
Kevin,



MDIFW is concerned with this proposed further reduction in minimum flows, down to 800 cfs at Ripogenus and 1,000 cfs at Millinocket. We anticipate there could be additional impacts on salmonid redds in these project areas. Before we can fully consider even lower flow releases that might further impact the natural resources, we would like a better understanding of the status of generation flow releases and other water conservation practices undertaken by Brookfield. Are the magnitude, duration, and frequency of generating flows being curtailed? A better understanding of any measures GLHA has been undertaking with their production releases is requested.

Also, we believe now is the time to examine alternatives for the coming spring given the high likelihood that the impoundment elevations will be significantly below the long-term average for a third consecutive year. Does GHLA have a plan for this spring, assuming the drought conditions continue through the winter? A wait and see approach will greatly challenge opportunities for meaningful and timely collaboration, including shared messaging to the public.

We understand GLHA's desire for quick concurrence, but we are requesting more information so that a more balanced resolution can be achieved, if possible.

John

**Subject:** RE: Minimum flow reduction proposals for Ripogenus and Millinocket

Kevin,

MDIFW is concerned with this proposed further reduction in minimum flows, down to 800 cfs at Ripogenus and 1,000 cfs at Millinocket. We anticipate there could be additional impacts on salmonid redds in these project areas. Before we can fully consider even lower flow releases that might further impact the natural resources, we would like a better understanding of the status of generation flow releases and other water conservation practices undertaken by Brookfield. Are the magnitude, duration, and frequency of generating flows being curtailed? A better understanding of any measures GLHA has been undertaking with their production releases is requested. Yes, generation on the Penobscot has been severely affected by the drought. For example, the Ripogenus Project generation reported to FERC for the most recent time period (October 1, 2020 – September 30, 2021) was 28% lower than the average generation reported for the previous 3 years. Since this generation report was filed with FERC last fall, generation at Ripogenus has continued to trend even

lower, averaging over 50% lower than the long-term average. As you also requested, below are examples of the water conservation measures that GLHA has implemented on the Upper Penobscot during the current drought:

- The Canada Falls, Seboomook, Caucomgomoc, and Ragged Lake Developments have been largely operating at minimum flow, or at a reduced minimum flow developed through agency consultation, since the current drought began in 2020.
- Through agency consultation, the Ripogenus spawning and incubation flows (which are required from October 15th – June 7th) have been set at 1,300 and 1,100 cfs in 2020 and 2021 respectively, much lower than the 1,700 cfs flow that had been set annually the previous 7 years. GLHA has not deviated from the current 1,100 cfs minimum flow since it was set in October.
- Ripogenus flows have been routinely reduced during non-rafting hours (i.e., from 5:00 p.m. to 8:30 a.m.) to conserve water storage in the Ripogenus impoundment.

Also, we believe now is the time to examine alternatives for the coming spring given the high likelihood that the impoundment elevations will be significantly below the long-term average for a third consecutive year. Does GHLA have a plan for this spring, assuming the drought conditions continue through the winter? A wait and see approach will greatly challenge opportunities for meaningful and timely collaboration, including shared messaging to the public. Due to the current low water levels and reduced snowpack, GLHA is proactively proposing the reduced minimum flows now in preparation for the spring, exactly because we do not want to take a wait and see approach. The water situation in the spring will dictate whether additional measures (such as reductions in whitewater rafting flows, which would further reduce generation) are necessary.

We understand GLHA's desire for quick concurrence, but we are requesting more information so that a more balanced resolution can be achieved, if possible.

Thank you for the additional information, Kevin. MDIFW supports the minimum flow reductions at both Ripogenus (to 800 cfs from the current 1,100 cfs) and at Millinocket (to 1,000 cfs from the current 2,000 cfs).

Good morning Kevin,

I've reviewed your responses to DIFW's inquiry, below, and appreciate a clearer understanding of GLHA's water management practices at the West Branch Hydro Projects. The Department concurs with GLHA's proposal to reduce flows at Ripogenus Hydro and Millinocket (Penobscot Mills hydro). I have just one follow on question;

1. What's GLHA's plan for water management when conditions improve and inflow increases? Will GLHA increase minimum flows as water is available until the projects return to licensed minimum flows, or does it plan to hold all or some of that water in the storage reservoirs?

Thanks,

Kathy

Hi Kevin,

The United States Fish and Wildlife Service concurs with the Department of Inland Fisheries and Wildlife and the Department of Environmental Protection regarding Great Lake Hydro American's February 23, 2022 request (i.e., the minimum flow reductions at both Ripogenus (to 800 cfs from the current 1,100 cfs) and at Millinocket (to 1,000 cfs from the current 2,000 cfs)).

Best.
Julianne

Just a quick update that the West Branch of the Penobscot River reservoirs have refilled nicely with the minimum flow reductions implemented at the Ripogenus and Penobscot Mills Projects in early March and from spring runoff, so GLHA will be returning to normal operations at the Projects beginning later today. Thank you for your cooperation with these water management actions, which were made in response to the drought and low water level conditions we've experienced on the West Branch over the last couple of years.

**Ripogenus Hydroelectric Project (FERC No. 2572), Yet Another West Branch of the Penobscot River Flow Violation Below McKay Station**

Recently, March 5th or 6th, 2022, West Branch of the Penobscot Rivers flows below McKay Station (West Branch) were reduced to 860 CFS. This flow violates a license minimum flow requirement of 1000 cfs as well as violating a spawning and incubation flow requirement of 1300 cfs. While the severity of environmental impacts of this dramatic flow reduction are unknown at this time, landlocked salmon (salmon) spawning success is threatened and aquatic communities' abundance further reduced. This most recent minimum flow violation by Great Lakes Hydro America is the most ecologically dramatic of the many 2021-2022 West Branch flow transgressions.

The Licensee's Pre-Application Document (PAD) proudly makes frequent reference to protection, mitigation, and enhancement (PM&E) measures. These measures were implemented by Great Northern Paper as part of the 1996 FERC license and for the most part have not been reevaluated in 20 plus years. The exceptions are lake level and flow management, so called, PM&E measures. The 2021 draining of the Ripogenus Impoundment and the dewatering of the West Branch, with the March 5, 2022 event being the most lethal, were obvious to all project visitors e.g., anglers, boaters, camp owners, campers, sightseers, etc. As the Licensee takes full credit for PM&E measures in the PAD, they must assume full responsibility for their actions when PM&E measures fail resulting in catastrophic biological loses e.g., loss/alteration of impoundment littoral zones,

the failure to provide suitable McKay Station flows resulting in the loss of flow into the Holbrook Bypass channel that was designed to support salmon spawning, incubation, and nursery life stages (Article 406), serious flow reduction and loss of downstream salmon spawning, incubation and nursey areas, and the loss of macro invertebrates communities abundance, function and diversity.

The Ripogenus license states*; Article 402 of the existing license requires minimum flows downstream of McKay Station into the West Branch as specified in Table 4.4-1. These flows may be temporarily modified if required by operating emergencies beyond the control of the Licensee and for short periods upon agreement between the Licensee and the Maine Department of Environmental Protection (MDEP) and Land Use Planning Commission (LUPC). Minimum flows may also be modified (to outflow approximates inflow) if required by hydrologic conditions beyond the control of the Licensee upon mutual agreement between the Licensee, USFWS, MDEP, LUPC, and MDIFW. Consistent with the August 19, 1997 FERC order approving and modifying the Water Management Plan, changes in flows below McKay Station are accomplished through the turbines; however, if necessary, GLHA will open a gate at Ripogenus Dam to augment flows.*

The key component of the above Article is: *hydrologic conditions beyond the control of the* licensee. Beginning in May 2021, the licensee had total control of Ripogenus storage as well as upstream storage in the Licensee's storage Project (P-2634). The Licensee's computer monitoring surely demonstrated falling lake levels with reduced inflow and weather forecasts provided little hope of significant precipitation. In managing storage, the licensee also chose to ignore Great Northern Paper's Water Management Plan. The use of 38 plus Billion Cubic Feet of useable storage including tributary inflow was a business decision designed to maximize energy production and profit. The licensee did so and depleted storage with total disregard of environmental needs. Fish, aquatic communities as

well as recreationalist paid the price and will continue to pay the price (in lost salmon reproduction) in 2022 and beyond.

The 1996 FERC Ripogenus License was based in part on the value of West Branch salmon fishery and “relatively stable base flows”. These conditions no longer exist. The 1996 license also provides some flow modification flexibility, however the licensee is required to consult with the resource agencies e.g., Maine Department of Inland Fisheries and Wildlife, the US fish and Wildlife Service and Maine Department of Environmental Protection. There are no FERC E-library filings that suggest possible consultations occurred. Another in a series of Ripogenus Project license violations that resulted in continuing environmental degradation.

If license conditions are to be meaningful, FERC needs to respond to the licensee’s continued disregard for conditions, guidelines and goals set forth in the 1996 FERC License. FERC must hold the licensee responsible for operational decisions, e.g., peaking, and high base flows, made when it was clear that no storage would be available to meet fall and winter environmental goals. FERC can not allow the Licensee to act as it pleases, the environmental communities will not survive, or survive in the manner described in the 1996 Environmental Impact Statement. Fish, aquatic communities and anglers need to be considered.

Thank you for the opportunity to comment.

March 13, 2022

Kimberly D. Bose,
Secretary Federal Energy Regulatory Commission First Street, N.E.
Washington, D.C. 20426

Subject: Ripogenus Project (FERC No. 2572); Minimum Flow Reductions Comments

Dear Secretary Bose:

I am writing in response to the letter submitted March 9, 2022 by Kevin Bernier of GLHA regarding minimum flow reductions in the Ripogenus Project. I greatly appreciate GLHA evaluating snowpack and recognizing the amount of water released from Ripogenus dam needed to be modified to support future water releases. In their letter, GLHA presents the drought as the sole cause of the current problem.

They claim, " *licensee for the Ripogenus (FERC No. 2572) and Penobscot Mills (FERC No. 2458) Projects, has been implementing water conservation measures on the Upper Penobscot since the current drought intensified beginning in 2020*," and provide the following as evidence of water conservation efforts:

> *1. The Canada Falls, Seboomook, Caucomgomoc, and Ragged Lake Developments have been largely operating at minimum flow, or at a reduced minimum flow developed through agency consultation, since the current drought began in 2020.*
>
> *2. Through agency consultation, the Ripogenus spawning and incubation flows (which are required from October 15th – June 7th) have been set at 1,300 and 1,100 cfs in 2020 and 2021 respectively, much lower than the 1,700 cfs flow that had been set annually the previous 7 years. GLHA has not deviated from the current 1,100 cfs minimum flow since it was set in October.*
>
> *3. Ripogenus flows have been routinely reduced during non-rafting hours (i.e., from 5:00 p.m. to 8:30 a.m.) to conserve water storage in the Ripogenus impoundment.*

I applaud these efforts, although I question the claim of reduced releases during non-rafting hours. Our experience on the lake and rivers has not reflected "routinely reduced flows during non-rafting hours." Throughout July and August of 2020 and 2021 we often saw releases above the minimum required and well beyond hours required. An example of daily releases is represented in the chart below, which is a screen shot from Brookfield's Water Flow site in August of 2021:

AS OF SAT AUGUST 14 11:41AM EDT

Total Flow 3100 cfs

| | 9:00 PM | 8/14/2021 | 8:00 AM | 1,800 |
| 8/14/2021 | 8:00 AM | 8/14/2021 | 5:00 PM | 2,200 |
| | 5:00 PM | 8/15/2021 | 8:00 AM | 1,800 |
| 8/15/2021 | 8:00 AM | 8/15/2021 | 5:00 PM | 2,200 |

As the Short-Term Schedule indicates, water was generously released during non-rafting hours far exceeding minimum requirements. Rafting releases were also beyond minimum license requirements as explained by GLHA, "*Project license requires that minimum whitewater recreation flows of between 2,000 and 2,300 cfs be released from the Project between 0830 and 1700 hrs. on a daily basis.* ***In a "dry" hydrologic year (such as 2021), the required minimum flows are 2,200 cfs on Saturdays and Sundays, 2,000 cfs on Mondays and Fridays, and 1,800 cfs on Tuesdays through Thursdays.*** *During other hours of the day* ***outside of the whitewater release time period (i.e., 1700 to 0830 hrs), requires a minimum flow of 1,000 cfs*** *from June 8th through October 14th.*

Analysis of the Scheduled Flow Chart clearly demonstrates releases exceeding minimum requirements by as much as 2400 cfs. Releases between 1700 to 0830 hours exceed minimum flows by at least 800 cfs. If flows *"set at 1,300 and 1,100 cfs in 2020 and 2021 respectively,"* are *"much lower than the 1,700 cfs flow that had been set annually the previous 7 years"* are recognized as an important water conservation effort, certainly flows of 800 -2400 cfs beyond minimum requirements are recognized as significantly excessive.

There is no question lake levels are low and dramatically impacted by the drought. It is important GLHA and all of the stakeholders recognize the low water levels are also the result of project operations. GLHA states, *"Recent surveys in the upper Penobscot drainage have shown average*

*water content in the snow to be about 20% below the long-term average. In addition, water levels are currently much lower than normal in both the Ripogenus (almost 22 feet below full pond) and North Twin (almost 8 feet below full pond) impoundments.*" Twenty percent below average snowpack does not result in Ripogenus Impoundment being 22 feet below full lake – excessive water releases in a time of drought does.

In their letter, GLHA explains the reduced flows, "*are the same minimum flows implemented as the result of the most recent (2001 – 2003) extended severe drought in Maine."* We purchased our camp in 2003, and spent a large amount of time in the fall of 2002 on the lake deciding to make the purchase. At that time, despite a severe drought, the lake levels were not nearly as low as they are now, as evidenced by the fact that we were able to park our boat on the first mooring, something that has quickly become impossible in recent early summers. Family pictures show the lake in the fall of 2002 and spring of 2003 much higher than lake levels in recent years.

The purpose of this letter is to provide both anecdotal and empirical evidence that the low lake levels are not only the result of the drought, but that the problem has been exacerbated by operational practices. My hope is that this will provide the Commission with a clearer understanding of what is truly happening on the waterways. I also hope GLHA will acknowledge how operations have contributed to the problem so mistakes can be corrected, and future operations can be modified and improved.

Ten years of historical operations data has been requested by nearly all NGOs and government agencies involved in this process. The data exists. Within this data lies the facts necessary to make informed, accurate decisions, as recent events illustrate.

Relicensing these dams is a colossal undertaking that can only be done with an honest, accurate understanding of the realities of the situation, and with all parties involved engaged in good faith, cooperative efforts. FERC has the immense responsibility to balance the needs of all stakeholders involved. This can only be done with a complete and accurate picture of what dam operations have been over the current owners tenure, and the impacts of those operations on the rivers and lakes, fish and wildlife, and recreational users.

Thank you for your time and consideration.

Sincerely,
Kathleen K Houston

Re: The Ripogenus and Penobscot Mills Projects P-2572 and P-2458

Great Lakes Hydro America's failure to meet 401 Water Quality Certification Articles and Protection, Migration and Enhancements Measures during 2021.

Great Lakes Hydro America (the Licensee) initiated the Licensing of the Ripogenus (P2572) and Penobscot Mills (P2458) Projects on June 8, 2021. During this process the Licensee has submitted numerous filings that demonstrate their failure to follow 401 WQC prescriptions. Additionally, the licensee has ignored measures suggested in the 1996 EIS and then listed them in the Preliminary Application Document (PAD) as Protection, Enhancement and Mitigations (PE&M) measures. The Licensee needs to be held to both legal standards and enhancement measures so often referred to in the PAD and subsequent filings. Stating that nothing has changed and "everything is great", simply is not supported by the March 23, 2022 "flow and elevation" filing and the Maine Department of Inland Fisheries and Wildlife's (MeDIFW) Chesuncook lake (Ripogenus Impoundment) October 8, 2021 filing. I contend that the Licensee needs to correct operating procedures that clearly violate 401 WQC articles or contradict PE&M statements made in the PAD. This filing requests that FERC immediately take the necessary actions to correct present and future operations that are impacting fish and aquatic communities and angler use and success in the Ripogenus Impoundment and all reaches of the West Branch. The areas of concern are;

- Article 402 – Ripogenus Project, Upper Gorge July-September 30 flows
- Article 406 - Ripogenus Project, Holbrook Bypass Channel Salmon Spawning and Nursery Flows
- Article 408 – Penobscot Mills Project, Irregular Flows
- Article 413 -Millinocket Stream, Spring and Fall Brook Trout Stockings

! The Use of the Water Management Plan

Upper Gorge:

Former MeDIFW Regional Biologist, Paul Johnson filed (October 8, 2021) comments on the PAD, noting that the licensee's present practice of providing surface flow into the Upper Gorge were not meeting the objective of Article 402, section 401 of the Clean Water Act. MeDIFW echoed this concern in its October 8, 2021 filing.

> "*It was the intent of MDIFW that the flows in the Upper Gorge would originate from a deep gate and provide a cool water attraction flow as adult salmon reached the upper river in July. However, the water is released from a sluice (surface) gate which is warm water. This water is warmer than the water passing through McKay Station into the river and is therefore ineffective as an attraction flow*."

Brookfield Renewable Energy/ Great Lakes Hydro America is a competent and well-run organization. During *due diligence* the Licensee surely became aware of goals and operating necessities required by License articles and PM&E measure presented in the 1996 EIS and the resulting FERC license. Still, despite complaints and study requests, the Licensee continues to ignore issues raised in numerous stakeholder filings and a very reasonable MeDIFW request has been ignored. However, this "pales in comparison" to the fact that the Licensee's lists the Upper Gorge flow as a PM&E measure when recent Upper Gorge flows are by surface discharge. The resulting flow act as a salmon repellent rather than an attraction flow. The existing Upper Gorge flow regime is exactly opposite of the MeDIFW request.

In recent years, the July 1 -September 30 period, flows into the Upper Gorge were 90 cfs of surface water though a "log sluice" gate. The assumption was that the remaining flow needed to meet the 100 cfs requirement was from leakage (12 Cfs recorded during a full pond 1991 measurement). However, the license says release. This implies an action, in this case, opening a gate. Leakage is passive and beyond control of the licensee and in fact, there are no current data reporting the amount of (any) leakage and change in (any) flow volume as the Ripogenus Impoundment head is reduced.

The present licensing schedule appears to be delayed and field collections are unlikely to be initiated by May 1, 2022. Another year's delay and another year of continuing impacts. During this transition period FERC can act to bridge the gap, by ordering the Licensee to either provide Upper Gorge flow through a deep gate or by requiring the Licensee to siphon off water (say 10-15 cfs) from below the McKay Station intake structure, say 55 feet below full pond elevation. Either method will reduce the Upper Gorge stream flow temperature. A return to the initial MeDIFW goal and conditions of Article 402 is a simple operation.

.Holbrook Bypass Channel:

The Holbrook Bypass Channel, Article 406, was designed at the request of MeDIFW in order to mitigate for the lack of young-of-the-year (YOY) salmon habitat in the West Branch below McKay Station. Two intake pipes were buried under a rocky berm along the northeast side of Holbrook Pool. One pipe with an adjustable valve, allowed for flows of 35 (June 1st) or 65 cfs (October). Mandated monitoring studies required in Article 406 and conducted during the years of "relatively stable base flows" determine that this mitigation measure was a success. Adult salmon spawned in the bypass channel and subsequent YOY production was excellent in earlier years. Monitoring studies ended in 2001.

During the summer and fall of 2021, low McKay Station flows resulted in reduced flow into the bypass area. On September 14, 2021 Licensee's staff photographed the upper Bypass Channel at a reported station flow of 1000 cfs (see the Licensee's September 30, 2021 filing). The two pictures show a flow that lacks surface turbulence and riffles, conditions needed for optimum YOY salmon production. Looking downstream from the intake gates, a long, flat stretch with an "unbroken" surface is apparent. Such waters are not suitable for YOY salmon and salmon production is lost or reduced under a 1000 cfs flow regime.

By November 2021, Holbrook bypass low flows became effectively no flow, and this very limited flow was not suited to spawning AND overwintering survival of eggs. The 2020 spawning year class and resulting 2021 salmon YOY production was lost during late summer and early fall low flow events. Then November 2021 salmon spawning was lost due to fall and (2022) winter dewatering, this will result in NO 2022 salmon YOY production. Two years of Article 406 mitigation lost and the West Branch salmon population will suffer in the coming years. While 2021 was a "dry

year", the Licensee was in complete control of Ripogenus storage and McKay Station Flow. On May 15, 2021 the Ripogenus Impoundment elevation was 933.77 (see March 23, 2022 filing) or about 23 BCF, the upstream Storage Project (P-2634) presumably in full license compliance, contained another 9 BCF. An additional 8+ BCF of inflow would eventually contribute to storage during the May 15-September 15 period. The resulting 40 BCF was enough water to meet both hydroelectric and PM&E measures. Instead, the Licensee chose to generate and drain the Ripogenus Impoundment, and eventually the West Branch, rather than meet PM&E measures so often cited in the PAD and subsequent filings. The FERC compliance section should require the Licensee to meet the WQC Article 406 condition as well PM&E measures it now boasts of so frequently.

Daily low evening flows e.g., 1000 cfs, not only impacted the above referenced salmon nursey area (both in the bypass and in downriver areas) but aquatic communities, fisheries and angling opportunity. The foundation of the 1992 Ripogenus Project License Application was "relatively stable base flows" and the accompanying "two wheel" (turbine) 2000 cfs flow when Mill energy demands were low. This was an environmentally proven mode of operation. The fishery below McKay Station was a "world class" fishery. MeDIFW referred to this river section as a "Destination Fishery". FERC now has an opportunity to protect the fish and aquatic insects below McKay Station by requiring the licensee to adhere to article 406 standards. Mandating McKay Stations discharges that provide a June 1st flow of 35 cfs into the bypass stream will meet multiple goals including downstream fish and aquatic communities' needs.

Penobscot Mills Project Flows

The 1996 License was based on Great Northern Paper's historical relatively stable West Branch base flow operations. It appears that the Licensee has changed from historical operations into a peaking mode in waters downstream of North Twin Dam and extending to the Medway Impoundment. For example, during August 12 and 13 of 2021, North Twin Dam outflows peaked at 3943 cfs before returning to the licensed minimum of approximately 2000 cfs (the Licensee's March 23,2022 filing). These peaking events appeared in other years and all other facilities. While well within the license WQC conditions, such flows are not "relatively stable" and impact fisheries and aquatic communities. The Licensee has yet to file the

requested hourly flow and elevation records for each facility. These records should be made public. A review of licensee' March 23, 2022 filing of *Daily operations data* listing "min.station" and "max.station" records indicate that there were numerous peaking flows events but the time frame is unknown. Minimum and maximum station flow differentials of 1000-1400 cfs were common below all facilities. FERC should require that the Licensee provide the requested hourly flow information, these data will demonstrate any daily flow fluctuations in response to energy demands.

During low flow periods, the West Branch provides much of the mainstem Penobscot River's flow, perhaps 90%. Thus, flow management of the West Branch (Penobscot Mills Project) impacts down river fisheries and aquatic habitat downriver of the Weldon Station (Mattacecunk Project P-2520). The entire mainstem Penobscot River below Weldon Station is considered critical habitat for the federally listed Atlantic salmon. The USGS West Enfield flow records, when viewed in graphical form, suggest upstream peaking events. The impact(s) of Penobscot Mills Project flow management on critical Atlantic salmon habitat in the mainstem Penobscot River should be considered.

Millinocket Stream, brook trout stocking

Article 413 requires *"The licensee shall implement an upgraded spring and fall brook trout stocking program to provide a seasonal fishery in Millinocket Stream. Each stocking shall consist of about 500 fish ranging in size from 1/3 to one pound,…."*.

Initially, Millinocket Stream hatchery brook trout were supplied by a private source rather than a public source, MeDIFW**.** A review of MeDIFW stocking records dating back to 2010 revealed that the licensee has been unable to meet Article 413 requirements in the last 11 years. The Licensee has consistently failed to meet the "spring and fall brook trout requirements" as spring stockings of trout "*1/3 to one pound*" have not occurred. The 2021 stocking of small, but catchable, 10 inch trout was an improvement but still failed to meet WQC Article 413 requirements. There were also a number of May stockings, when two inch fry were stocked. These efforts also failed to meet Article 413 requirements. Stocking brook trout fry in Millinocket Streams makes no biological sense. The reason for stocking brook trout fry is unclear. This alarming failure to meet an important

Article 413 mitigation measure was not revealed in any of the Licensee's frequent filings. I urge FERC to correct this licensee violation by requiring the Licensee to stock "*1/3 to one pound*" brook trout in the spring.

The Use of the Water Management Plan:

The Licensee has mostly ignored the 1996 Water Management Plan (WMP) and arbitrarily set up its own water management plan; a peaking operation driven by the market for electric power that conflicts with environmental needs. Circa 1990, Great Northern Paper hired highly credentialled Dr Nathan Burris PhD to develop a Water Management Plan that evolved into a Water Use Plan (WUP) for the West Branch drainage. The WUP was used in the early years of the current license but may have been abandoned by the Licensee. I say "may" because the licensee sometimes claimed to follow their own water management scheme while at other times referring to the WUP. The best and perhaps only example of "picking and choosing" water management guidance, the WUP, or using their own mysterious water management plan that ignores stated license goals is found in a footnote to Table 4.4-1 of the PAD;

*"The whitewater flow for each month from May through September is determined on the first day of each month based on an analysis of Total Available Water as described in the Water Use Plan in the application for new license filed with the Commission on December 17, 1991"*

There are no upper flow limit associates with "whitewater flow" releases. The March 23, 2022 flow spreadsheets demonstrate that during 2021, the Licensee routinely operated in a peaking mode, e.g., 3000 cfs, during periods before, during and after boaters were on the river. Market driven energy needs for peaking are simply called "Whitewater flows". MeDIFW questioned water management in its October 10, 2021 filing, questioning 3000 cfs flows during draught conditions*. "MDIFW observed on several occasions in the winter and summer of 2021 that the Licensee was indeed running in excess of 3,000 cfs when lower flows were required by the license;*". By August 2021 Ripogenus Impoundment storage was clearly being rapidly depleted and many PM&E measures threatened. Still the Licensee continued to operate in a peaking mode. The WUP, including "*an analysis of Total Available Water as described in the*

*Water Use Plan"* referenced in the PAD, was clearly arbitrarily ignored in the summer of 2021.

The PAD states that the licensee measures snow in late February/early March and uses the result to "manage" storage. The relevance of "snow depth" is not clear. The critical factor relating to potentially available storage, is water content in the snowpack. Equally bewildering, is the apparent lack of knowledge of the North Branch and South Branch (hydraulically controlled by the Canada Falls facility) USGS monitoring stations and the unwillingness to use real time inflow data. A review of the 2021 USGS North Branch station and to a lesser degree the (hydraulically controlled) South Branch Station flow data provides clear and irrefutable evidence that the Licensee violated the "or inflow" provision of the Ripogenus' s Project Article 406 during the late summer and early fall of 2021.

"*The 1991 Water Use Plan (i.e., the licensee's proposed operation alternative) was developed prior to issuance of the Projects' existing licenses and was the basis for the operational requirements included in the Projects' 1996 FERC Licenses. However, as compared to the Water Use Plan, the Projects' current operations are defined by the requirements of the Projects' licenses. Therefore, the 1991 Water Use Plan is not a "management plan" consistent with other management plans resulting from a relicensing proceeding"* (PAD 1-12).

The above quote is simply the Licensee's opinion. Other than the obvious change to a peaking operation (that the Licensee has yet to acknowledge), the Licensee provides no explanation of the above statement. I have seen no FERC filings where the Licensee has filed statements concerning abandonment of the FERC license guidelines. The change in operation was a deliberate business decision to maximize generation. In the PAD the Licensee states "*Therefore, the 1991 Water Use Plan is not a management plan consistent with other management plans resulting from a relicensing proceeding*." The WUP is the foundation of the 1996 Licenses. FERC, in the 1996 EIS, found the WUP compatible with existing fish and aquatic communities and "boating" needs while at the same time meeting other required PM&E measures. The Licensee implies nothing has changed but then states in the PAD that the WMP is no longer valid. So, what has changed to the degree that the WUP is not "consistent with other management plans"? The Licensee referenced water management frequently and boasted about it as a

PM&E measure. Thus, it is obvious that the Licensee has some type of a water management plan with starting and ending points. However, “generate and drain” is not a water management plan as the end points are a dry impoundment and an environmental disaster. It is time for the Licensee to share the parameters used in managing storage and flow in all project waters with the agencies, stakeholders and FERC.

It is time to develop a new Water Management Plan. MeDIFW in its October 8, 2021 filing echoed a similar sentiment, *“We view this upcoming relicensing process as an opportunity to review and fine tune the water management for the Ripogenus Project.”* Simply stated, at this time, there is simply no peer reviewed water management plan for the West Branch for the West Branch between McKay Station and the Medway facility. In its frequent filings, the licensee constantly talks of water management and then demonstrates that none exist. It is obviously that in the case of fisheries, aquatic communities, loons, camp owners and boaters, their needs were not considered during 2021 and other years. The West Branch River system is out of balance. As soon to be mandated 2022-2024 studies are completed, a list of competing needs will be developed. In order to balance the needs of various users, FERC staff will require information on available storage and flow requirements. Without a peer reviewed water use plan, FERC staff’s task will be impossible.

Despite the Licensee’s warning of another “dry year” in its March 9, 2022 filing, heavy rains have greatly improved storage conditions and the impoundments are filling or already full. To those of us involved in this licensing(s), we are happy to see the Licensee enjoy an apparent (at this time) “wet year”. Wet years are good for hydroelectric generation, and even better for fish and aquatic communities. A win for all parties. Still, environmental concerns remain. As an interim measure, I urge FERC to require that Holbrook bypass flows be maintained as envisioned by Article 406. This can be accomplished by ordering that minimum McKay Station operating flows be set between 2000 -2200 cfs. I also request that FERC implement MeDIFW’s ramping request (October 8 2021 filing) of a 25% change per hour outflow below all project facilities. Ramping rates are common to all new FERC licenses/401 WQCs and the Licensee is required to ramp at Caucomgomoc Lake Dam (P-2634), Stone Dam (P-2572) Article 412 (7), and the Magpie River (Ontario, CA) to name a few facilities. A new license is at a minimum four years

away. The ongoing impacts to fish and aquatic communities needs to be corrected. Current project operations are out of balance, heavily skewed to power generation. Requiring the Licensee to adhere to the many license articles and PM&E measures it so often boasts of would be a good start.

Thank you for the opportunity to comment on the many license violations that resulted from Licensee's 2021 operations of the Ripogenus and Penobscot Mills Projects.

Brookfield Renewable

April 27, 2022

***Via Electronic Filing***

Kimberly D. Bose, Secretary
Federal Energy Regulatory Commission
888 First Street, NE
Washington, DC 20426

**Subject:** **Ripogenus Hydroelectric Project (FERC No. 2572-133)**
**Penobscot Mills Hydroelectric Project (FERC No. 2458-247)**
**Response to Stakeholder Comments on Revised Study Plan**

Dear Secretary Bose:

Great Lakes Hydro America, LLC (GLHA), a subsidiary of Brookfield Renewable and Licensee of the Ripogenus Hydroelectric Project (FERC No. 2572) and the Penobscot Mills Hydroelectric Project (FERC No. 2458) (collectively referred to as the "Projects"), herein files with the Federal Energy Regulatory Commission ("FERC" or "Commission") responses and clarifications to select stakeholder comments on the Revised Study Plan (RSP) for the relicensing of the Projects. The Projects are located on the West Branch of the Penobscot River and Millinocket Stream in Piscataquis and Penobscot Counties, Maine.

On June 11, 2021, GLHA filed the Notices of Intent and Pre-Application Document (PAD), which initiated the formal relicensing proceeding to obtain two separate new licenses for the continued operation of the Projects through the Commission's Integrated Licensing Process (ILP). Subsequently, FERC issued Scoping Document 1 (SD1) on August 10, 2021, and held daytime and evening virtual scoping meetings on September 9, 2021.[1] Additionally, on the afternoon of September 9, 2021, GLHA hosted a virtual environmental site review. On November 22, 2021, FERC issued Scoping Document 2 (SD2). Also on November 22, 2021, GLHA filed a single Proposed Study Plan (PSP) for the Projects. GLHA hosted a two-day virtual PSP meeting on December 15 and 16, 2021. On March 23, 2022, GLHA filed a RSP for the Projects.

Via letter dated April 1, 2022, the National Marine Fisheries Service (NMFS) requested an extension of time to file comments on the RSP. Via letter dated April 7, 2022, FERC approved an extension of time until April 28, 2022, for stakeholders to file comments on the RSP and until May 13, 2022, for FERC to issue the Study Plan Determination for the Projects. Given these extensions of time, GLHA is providing clarifications and responses to select stakeholder comments regarding the RSP. GLHA believes that this additional information will provide stakeholders with additional needed information and support the Commission's development of the Study Plan Determination.

[1] As specified in SD1, the Commission did not conduct in-person public scoping meetings or in-person environmental site reviews due to concerns with COVID-19.

**April 1, 2022 Letter filed by American Whitewater and Appalachian Mountain Club (AW-AMC)**

**AW-AMC Comment on Whitewater Boating Assessment Study**

Specific to the West Branch Below Stone Dam, SD2 and the comments of AW, AMC and Maine Department of Conservation, Division of Parks and Public Lands on the PSP requested that the West Branch below Stone Dam be assessed to adequately evaluate the needs and opportunities related to this resource for whitewater boating and other recreation. In the RSP, related to Stone Dam in section 5.0, AW and AMC believe the licensee is seeking to justify their lack of interest in following the Whitaker 2005 methodology by arguing that flows needed for such an analysis cannot be provided. AW and AMC find this assertion to be unclear and inconsistent with other publicly available information related to the operating parameters of the Stone Dam.

Though the licensee claims that the inflatable flashboards that have replaced the old gate structures at Stone Dam prevent the licensee from conducting a controlled flow study in this reach, AW and AMC find this contradictory to filings on this project to the Low Impact Hydropower Institute in their application and the reviewer's report in that docket (https://lowimpacthydro.org/lihi-certificate-167-millinocket-dolby-hydroelectric-project-maine/). Regarding the Stone Dam inflatable structure, the LIHI docket notes that Stone Dam may be used to attain the 2,000 cfs minimum flow downstream of the Millinocket Project when the Millinocket project is offline. The LIHI docket notes that, "*During periods of high seasonal flows or whenever abnormal conditions occur such that turbine flow [at the Millinocket Project] cannot be passed to achieve the 2,000 cfs minimum flow, the pneumatic rubber flashboard system [at Stone Dam] is deflated to release flows in an expeditious effort. When this occurs, a two-minute siren warning is initiated and a safe flow of 200 cfs is released for fifteen minutes. Increases of 400 cfs per hour are made until either the required downstream flow is met, the elevation at Stone Dam falls to 459.45 ft msl or the pneumatic rubber flashboard system is fully deflated. The ramping down of flows in the Back Channel is initiated once turbine hydraulic capacity is restored or seasonal flows start returning to normal.*" Provided that this information is accurate, it appears that Stone Dam can be operated in such a manner to assess whitewater paddling with an on-water component as part of the study if deemed necessary after Whitaker Level 1 study through single flow or multiple flow on-water study. This should be corrected in the Study Plan Determination.

**GLHA Response**

GLHA has reviewed the above-referenced information from the LIHI docket regarding the operation of the pneumatic rubber flashboard system at Stone Dam and provides clarifying information herein.

GLHA notes that LIHI docket information is consistent with the Water Management Plan for the Penobscot Mills Project, filed for Commission approval on April 9, 1997. The plan had been prepared in accordance with License Articles 401, 402, 403, 404, and 408 and was approved by Commission order on September 3, 1997.

The pneumatic flashboard system at Stone Dam is operated in support of public safety and to address abnormal operations (e.g., unplanned outages). Whereas GLHA operates the pneumatic flashboard system as such, it should not be interpreted that sufficient control of flows from Stone Dam exists to support a controlled flow study.

Minimum flows are released from Stone Dam using a procedure that incorporates ramping to avoid public safety concerns associated with an abrupt increase in flows downstream of Stone Dam. To provide the approximately 200 cfs public safety ramping release from Stone Dam, the control center partially deflates the pneumatic flashboard system. Prior to and during this deflation, the control center sounds the public safety siren for 6 minutes to notify downstream users of the increased flow entering the stream channel. During the public safety ramping release, the control center also observes via cameras the water flowing over the pneumatic flashboard system for the 15-minute duration to visually verify the deflation and estimated flow.

While the pneumatic flashboard system has a general gate discharge curve associated with it, the system, unlike pneumatically actuated gate systems, does not deflate consistently and, as such, does not release precise outflows. Although the pneumatic flashboard system at Stone Dam cannot release precise outflows, it is manually adjusted (as there is no automatic control) by the control center to maintain a stable head pond in compliance with the Penobscot Mills FERC license. As a result, the pneumatic flashboard system at Stone Dam is not capable of consistently providing the precise or sustained flows necessary for conducting a controlled flow study in this reach.

**AW-AMC Comment on Recreation Study**

Though AMC and AW appreciate the inclusion of a recreation user intercept surveys in the study methodology, we request that the study methodology also include an online survey, input from a stakeholder working group, and key person interviews with organizational representatives from user groups, representatives of camp owners and other recreation related interests, such as outfitters. It is not practical for our organizations or, for example, a camp owner on one of the lakes, rivers, or upland areas to be expected to travel to a FERC-approved recreation site to complete the survey, nor does the survey instrument speak to the feedback of these audiences as a broader representation of the needs, opportunities and issues that would be brought forward by these audiences.

**GLHA Response**

GLHA would like to clarify that the proposed study includes an online version of the recreation user survey. The survey boxes that GLHA will be deploying at each of the Project recreation sites will be displaying a QR code which, when scanned with a cell phone, can be used to find an online version of the recreation user survey. This method has been used effectively at numerous other hydropower projects and is a good way to provide online access to the survey.

Regarding the availability of the recreation user survey (or the QR code to complete the survey online) by those accessing the Project impoundments from locations other than the Project recreation sites, GLHA notes that the recreation user survey is focused primarily on understanding how the FERC-approved Project recreation sites are being used, and whether the facilities and amenities provided at the sites are functioning well and meeting their intended purpose. For this reason, it is appropriate to provide the surveys and QR code for online survey access at the Project recreation sites. That said, in their comments on the RSP, the Bureau of Parks and Land (BPL) asked how users of the remote campsites will be surveyed. To address this concern, GLHA will work collaboratively with BPL to install additional survey boxes at the boat launch locations indicated by BPL that are primarily used to access the remote campsites on the Ripogenus impoundment.

**April 7, 2022 Letter filed by Maine Department of Environmental Protection (MDEP)**

**Comment on Fish Assemblage Study**

In its comments on the Proposed Study Plan, the Department requested a Fish Assemblage Study that would be used to demonstrate, in part, whether the Projects meet applicable water quality standards. Specifically, the impounded waters must support all species of fish indigenous to those waters. The results of the Fish Assemblage Study would also be used as evidence that could demonstrate attainment of the designated use of habitat for fish and other aquatic organisms.

In the RSP, Great Lakes does not adopt the Department's requested Fish Assemblage Study, and instead proposes to conduct a Fishery Assessment as part of the Impoundment Aquatic Habitat Assessment component of the Water Quality Study. The Fishery Assessment would not involve any scientific sampling of fish populations. Instead, it would rely on existing information and interviews with various parties.

Although Great Lakes did not directly address the Department's request in its rationale for not adopting the Fish Assemblage Study, it did address a similar study request from a stakeholder group. Great Lakes appears to base its decision not to adopt the Fish Assemblage Study on its assertions that existing information is sufficient [section 5.9(b)(4)], that study results are not likely to inform potential license conditions [section 5.9(b)(5)], and that the study methods proposed by the stakeholder group (gill netting) are not consistent with generally accepted practice in the scientific community [section 5.9(b)(6)].

The Department disagrees with Great Lakes' assertions. First, existing information would not be sufficient to demonstrate that the Projects are currently meeting water quality standards. Historical and anecdotal data could be useful for fisheries managers, but it is unlikely to provide sufficient, defensible data for the Department to determine that the Projects' currently support all indigenous species of fish. Comprehensive, scientific sampling of fish populations would provide sufficient data to draw conclusions about the Projects' effects on water quality [section 5.9(b)(4)]. Second, the results of a Fish Assemblage Study would directly inform potential conditions that the Department could require in any Water Quality Certification it would issue for the project. Study results would be used to demonstrate attainment of

water quality standards related to fish populations in addition to providing evidence that the Projects meet water quality standards related to aquatic habitat more generally. If evidence of nonattainment is found, the Department will use the study results to inform the development of measures to mitigate for the Projects' effects on water quality. This is critically important to the relicensing proceeding, because FERC must include Water Quality Certification conditions in any new licenses for the Projects [section 5.9(b)(5)]. Third, the Department did not provide specific methods in its request since this type of study is commonly conducted in many FERC relicensing proceedings. Great Lakes' response focused on their concerns with the stakeholder group's proposed methods for collecting fish samples (gill netting). Great Lakes did not discuss any other generally accepted, and more commonly used, practices that the scientific community typically uses in fish assemblage studies, such as electrofishing. Due to this omission, Great Lakes' response did not fully address the study criteria, nor does it provide a basis for Great Lakes to not adopt the Department's requested study [section 5.9(b)(6)]. For these reasons, the Department requests that FERC determine that Great Lakes must complete a Fish Assemblage Study.

**GLHA Response**

To demonstrate that the Ripogenus Project meets applicable water quality standards, GLHA proposed in the RSP to complete additional data review and meet with regional Maine Department of Inland Fisheries and Wildlife (MDIFW) biologists who have current, first-hand knowledge of the existing Chesuncook Lake fishery to identify and describe indigenous species that are known to occur. In addition, GLHA proposed a macroinvertebrate study at the Ripogenus impoundment and aquatic habitat studies at the North Twin and Millinocket Lake impoundments to determine if aquatic life standards are supported in the Project areas. GLHA did not propose aquatic habitat assessments for the Millinocket (Quakish Lake and Ferguson Pond), Dolby, and East Millinocket impoundments because they are operated in run-of-river mode, which does not result in impoundment drawdowns under normal operations; MDEP typically does not require impoundment aquatic habitat studies for projects operated in run-of-river mode.

As described in the RSP, indigenous fish species known from the region include brook trout, yellow perch, white sucker, rainbow smelt, longnose sucker, lake whitefish, lake chub, golden shiner, fallfish, creek chub, common shiner, burbot, brown bullhead, and blacknose dace (Lakes of Maine 2022[2]). Most of these species are common throughout Maine waters. As described in Table 5-4.3 of the PAD, GLHA has previously documented that the Ripogenus impoundment supports these indigenous game and non-game fish species. The Licensee collected 18 species of fish in the Ripogenus impoundment as part of the last relicensing, including all known indigenous game and non-game fish species.

GLHA notes that the MDIFW, the principal state resource agency responsible for fisheries management and monitoring, did not request site-specific fisheries studies given the considerable

[2] Lakes of Maine. 2022. Database of Maine Lakes. Online [URL]: https://www.lakesofmaine.org/index.html?r=1650984792. Accessed April 14, 2022.

body of knowledge and their overall understanding of the fish assemblage in the Ripogenus Project area. MDIFW noted in its comments on the PAD (October 8, 2021) that there is an "*extensive history of inland fisheries studies associated with the Ripogenus Project completed in preparation for the 1996 license, and these studies need not be duplicated unless there are identified data gaps, or changes in operation that may impact the fisheries resources*." MDIFW also noted that the "*inland fisheries management goals for the Ripogenus impoundment and river have not changed since the last license was approved*."

In addition to the fisheries information collected during the previous relicensing effort, MDIFW has indicated that there is additional existing information on fishery resources in Chesuncook Lake of the Ripogenus impoundment that demonstrates the waterbody continues to support the indigenous fish species. GLHA spoke to the MDIFW Regional Biologist responsible for fisheries management at the Ripogenus Project on April 15, 2022, to discuss the fishery assemblage in Chesuncook Lake. During the call, MDIFW conveyed again that they have a good understanding of the Ripogenus impoundment fish community, and that there are more recent data (e.g., creel angler data and fish stomach content data) that can demonstrate the impoundment supports the indigenous fish assemblage. The following is a brief summary of the discussion with MDIFW during the April 15th conference call:

- MDIFW has a good understanding on species composition in Chesuncook Lake and is comfortable with the information that is available.
- No exotic species are known to occur.
- MDIFW offered to generate a species list from recent and past angler creel data (1,000s of hours of fishing records) that will document indigenous game and non-game species.
- MDIFW may have information from stomach content analysis that could supplement the species list.

On April 25, 2022, MDIFW provided additional data to GLHA consisting of raw data and a summary of data collected from the Ripogenus Impoundment between 1996 and 2021. The data summary provided by MDIFW is provided as an attachment to this letter.

Consistent with the approach that GLHA proposed in the RSP, GLHA will continue to work collaboratively with MDIFW staff to obtain and understand the existing fisheries data available for the Ripogenus impoundment. Additionally, GLHA will process and evaluate the raw data provided by MDIFW and provide a detailed summary of the data in the ISR to demonstrate the current make-up of the fish community.

GLHA's approach to compile and review existing contemporary data and work with MDIFW regional biologists to document that Chesuncook Lake continues to support the indigenous fishery assemblage, along with the proposed macroinvertebrate study in Chesuncook Lake and the aquatic habitat studies at the North Twin and Millinocket Lake impoundments, is a reasonable

and logical approach to determining if the structure and function of the waterbodies in the Project area are maintained.

Existing data from the previous licensing process, more contemporary data (e.g., MDIFW creel data), and professional input from MDIFW biologists will allow GLHA to document that the indigenous species assemblage in Chesuncook Lake is supported without the need for comprehensive, labor-intensive, and costly baseline fish assemblage studies throughout the Project area requested by TU and MDEP.

GLHA also notes that although electrofishing and other netting methods (e.g., seining, trap-netting) are common techniques for sampling shallow, near-shore habitats, it is unlikely that these methods (recommended by MDEP) will capture deep water or pelagic fish species (e.g., lake trout and lake whitefish), so they will only confirm the presence of common, near-shore fish species such as perch, minnows, and fallfish, which are already known to occur.

**April 7, 2022 Letter filed by Maine Council of Trout Unlimited (TU)**

**Comment on Stranding Evaluation Study**

TU submitted study requests for two types of studies: a Ripogenus Flow Excursion Study and a series of Fish Assemblage Studies correlating to the reaches described in the Pre-Application Document. In its Proposed Study Plan (PSP), Brookfield stated the Historical Operations Data and Assessment Study would document any such deviations from project minimums; however, the proposed study did not account for the stranding study component of our requested Flow Excursion Study. Accordingly, TU proposed a Stranding Evaluation Study in its PSP Comments.

**GLHA Response**

GLHA's rationale for not adopting the TU-requested Stranding Evaluation Study is consistent with that provided in the RSP in response to the Ramping Study requested by Mr. Ed Spear. GLHA believes that information collected and reported from other proposed studies, such as the Historical Operations Data Assessment Study, will provide information on how the Ripogenus Project has been operated, including flows provided by McKay Station. Additionally, fieldwork to be performed in the West Branch below McKay Station for other studies will provide additional information regarding flows in the West Branch in relation to aquatic resources.

Concurrent with this filing, GLHA is providing a copy of this letter to all parties listed in the attached distribution list, which can also be downloaded from FERC's eLibrary system at https://www.ferc.gov/docs-filing/elibrary.asp by conducting a search using the docket numbers p-2458 and/or p-2572.

If you have any questions regarding this letter, please contact me by phone at (207) 775-5605 or by email at randy.dorman@brookfieldrenewable.com.

Sincerely,

Randall Dorman

# Summary of MDIFW Species Data from Chesuncook Lake 1996 to 2021

**IFW Clerk Surveys (completed by our staff)**

Winter: We conducted winter clerks surveys in 8 years during the period 1996 – 2021

Summer: We conducted summer clerk surveys in 4 years during the period 1996- 2021

Data summary all years/all seasons:

Total Angler days: 1,821

Total Angler Hours: 10,444

| Species | # Reported (all sizes) |
|---|---|
| Brook Trout | 25 |
| Cusk | 222 |
| Fallfish | 70 |
| Lake Trout | 13 |
| Landlocked Salmon | 2087 |
| Lake Whitefish | 7 |
| Smelt | 390 |
| Splake | 20 |
| White Perch | 300 |
| Yellow Perch | 355 |

# Summary of MDIFW Species Data from Chesuncook Lake 1996 to 2021

**Voluntary record book data**

Winter: We have data from 24 years during the period 1996 – 2021

Summer: We have data from 23 years during the period 1996- 2020

Data summary all years/all seasons:

Total Angler days: 2,777

Total Angler Hours: 15,523

| Species | # Reported (all sizes) |
|---|---|
| Brook Trout | 28 |
| Cusk | 87 |
| Fallfish | 64 |
| Lake Trout | 22 |
| Landlocked Salmon | 6,318 |
| Smelt | 7 |
| Splake | 32 |
| White Perch | 3,474 |
| Yellow Perch | 171 |

MDIFW Age and growth data – These are fish that our staff have handled during creel surveys. They are typically measured, weighed, scale samples and a subsample of stomachs taken.

| Species | # Examined | Mean Length ( mm) | Ages represented |
|---|---|---|---|
| Brook Trout | 4 | 352 | 2-4, 6 |
| Cusk | 17 | 501 | |
| Lake Trout | 7 | 711 | 8,10,17 |
| Landlocked Salmon | 428 | 405 | 3-8 |
| Splake | 19 | 415 | 3-6 |

**Summary of MDIFW Species Data from Chesuncook Lake**
**1996 to 2021**

Food Habits data – Stomach samples are taken during winter clerk surveys. Food items are identified, enumerated, and volumes measured by displacement.

| Species with Stomachs Examined | # examined |
|---|---|
| Brook Trout | 4 |
| Lake Trout | 16 |
| Landlocked Salmon | 376 |
| Splake | 7 |

# Summary of MDIFW Species Data from Chesuncook Lake 1996 to 2021

**Notes**:

Brook Trout – Population is limited by competition by warm waters species such as white perch, yellow perch, fallfish, and suckers. Brook trout are present in the lake but not abundant. Likely abundant in the tribs.

Cusk: Abundant

Fallfish: Abundant

Lake Trout: Fishery was maintained through a stocking program. Stocking was terminated in 1994.

Landlocked Salmon: Abundant

Lake Whitefish: We are not clear on the status. They do not show up in the winter clerk surveys. If they were abundant, we would expect to see them. Anglers have reported them, but they may be misidentified round whitefish or, most likely, fallfish. The last lake whitefish IFW sampled were in 1970 during a gillnetting operation. Seventeen were taken that ranged in size from 415-520 mm.

Smelt: Present. Although not as abundant as in past years, the population is still considered stable. Anglers that target smelt are successful and smelt are commonly found in salmonid stomachs.

Splake: Splake occasionally drop downstream from Ragged Lake and Deer Pd into the Chesuncook System. Considered incidental.

White Perch: Abundant

Yellow Perch: Abundant

White Sucker: Abundant

FEDERAL ENERGY REGULATORY COMMISSION
Washington, D. C. 20426

OFFICE OF ENERGY PROJECTS

Project No. 2572-119—Maine
Ripogenus Hydroelectric Project
Great Lakes Hydro America, LLC

**September 13, 2011**

Mr. Kevin Bernier
Brookfield Renewable Power Inc.
Great Lakes Hydro America, LLC
1024 Central Street
Millinocket, Maine 04462

Subject: Article 401- Minimum Flow Deviation

Dear Mr. Bernier:

Thank you for your letter filed on July 15, 2011, notifying the Commission of a temporary modification in the minimum flow requirement, which is required under Article 401 of the license for the Ripogenus Hydroelectric Project, FERC No. 2572.[1]

Article 401

Article 401 requires you to maintain a minimum flow of 100 cubic feet per second (cfs) from the Ripogenus Dam into the Upper Gorge of the West Branch of the Penobscot River from July 1 until September 30.

Summary of Events

By letter dated July 15, 2011, you notified the Commission that a deviation in the minimum flow requirement from the Ripogenus Dam occurred from July 1 to July 5, 2011. Specifically, you stated that on July 5, 2011, you discovered that the Upper Gorge flow of 100 cfs had not been started on July 1, as required by Article 401. Immediately upon discovering this error, technicians were dispatched to the Ripogenus Dam and the minimum flow of 100 cfs was established at 3:50 P.M on July 5. In your July 15, 2011 letter, you state that the reason that the minimum flow had not started on July 1 was a result of the Penobscot Resource Manager's failure to enter the date in his Microsoft Outlook Calendar in order to provide adequate notification for the flow change.

[1] *Great Northern Paper, Inc.*, 77 FERC ¶ 61,066 (1996).

This event has subsequently been added to the Penobscot Resource Manager's Outlook calendar, and all other license flow requirements have been verified as being present in the calendar. In addition, you recently implemented a new management system, part of which will allow you to better manage maintenance tracking and planning. All license flow changes are now in the management system and will act as another layer of assurance that the flow changes will be made on time. Furthermore, the Penobscot Water Resource Manager will review license requirements on a weekly basis to ensure that all required changes are identified quickly and planned for accordingly.

Conclusion

Based upon review of the available information, we have determined that the temporary deviation of the minimum flow at the Ripogenus Project from July 1 to July 5, 2011, was due to a failure in tracking the flow changes as required by the license, and therefore was the result of operator error. However, once you determined the cause of the interruption, you promptly rectified the problem, and have subsequently implemented corrective measures to ensure that the seasonal flow changes will occur on schedule. Therefore, we have determined that the temporary deviation was a violation of your license, and we will include the incident in the compliance history for the Ripogenus Project, but without recommending any penalties at this time. However, we remind you that failure to implement seasonal flow requirements for the Ripogenus Project may result in penalties in the future.

Thank you for your cooperation in this matter. If you have any questions regarding this letter, please contact Kelly Houff at (202) 502-6393, or by email at Kelly.Houff@ferc.gov.

Sincerely,

William Guey-Lee
Chief, Engineering Resources Branch
Division of Hydropower Administration

June 23, 2015

**FERC Project No. 2572**
**Article 402**

Secretary Kimberly S. Bose
Federal Energy Regulatory Commission
Mail Code: DLC, HL-11.2
888 First Street, N.E.
Washington, D.C. 20426

Dear Secretary Bose:

**RE: Ripogenus Project 2572; Article 402 Compliance; Flow Excursion due to McKay Station Outage**

Great Lakes Hydro America, LLC (GLHA), licensee for FERC Project No. 2572-ME (Ripogenus) in Maine, is filing this letter to report an approximately one-hour reduction in outflow from the Project's McKay Station to the West Branch of the Penobscot River on June 13, 2015. As described below, after discovery of the excursion, GLHA promptly remedied the triggering transmission line pole cross arm failure, and opened a gate temporarily to ensure that the outage flow will continue to be met should another excursion occur. Further remedial measures to prevent recurrence are also being explored, as described below.

## Background

Article 402 of the Project license requires certain minimum flows, including a minimum flow of 400 cfs during unit outages at the Project's McKay Station. Specifically, the Article 402 outage flow requirement states:

> *"Outage flows (during failure of generating units at McKay Station) of 400 cfs, with scheduled minimum flows to be resumed as quickly and practically as possible by releases from Ripogenus dam if necessary, but in no event in more than three days following the initial outage".*

Article 402 further states that minimum flows at the Project may be temporarily modified if required by operating emergencies beyond the control of the licensee, with subsequent notification to FERC within 10 days of the flow modification.

## Description of the Excursion

On Saturday evening, June 13, 2015, at 18:27 hours, a pole cross arm on the Ripogenus transmission line failed and hit the ground, which started a small fire that GLHA promptly extinguished. The line failure tripped McKay Station to cease operating, thereby reducing its outflow to the West Branch of the Penobscot River to approximately 100 cfs. McKay Station has a minimum flow system designed to ensure continued outflow of 400 cfs during a station outage, but that system malfunctioned and activated only one of the three units. As a result, the minimum flow dropped below the required minimum 400 cfs outage flow level for 63 minutes.

Brookfield

Brookfield Renewable Energy Group
New England Regional Operations Center
Great Lakes Hydro America, LLC
1024 Central Street
Millinocket, Maine 04462

Tel 207.723.4341
Fax 207.723.3948
www.brookfieldrenewable.com

GLHA promptly responded by opening crest gate #1 at Ripogenus Dam, which increased the river flow to approximately 1,320 cfs, thereby resuming the scheduled minimum flow. At 20:05, GLHA opened crest gate #2 at the Dam, thereby returning total river flow to about 2,550 cfs. McKay Station remained down until transmission line repairs were completed and the line was re-energized at approximately 13:00 hours on June 16, 2015.

**Steps Taken to Prevent Reoccurrence**

As noted, as a first step toward preventing recurrence, GLHA repaired the transmission line. In the short-term, GLHA has opened a gate at Ripogenus Dam to ensure that the outage flow is met in the event of another station trip. GLHA will keep this gate open until GLHA is confident that the minimum flow system will function properly and provide the required 400 cfs flow during any subsequent station outages. In addition, GLHA initiated a detailed internal investigation, which is still ongoing, and has been troubleshooting the cause for the minimum flow system malfunction. After the cause(s) of the transmission line failure and system malfunction is/are fully identified and rectified, GLHA will update the Commission with any additional corrective measures that result.

**Conclusion**

The excursion detailed in this report was the result of both an unscheduled interruption in generation at McKay Station (due to a transmission line failure) and a malfunction of the station's minimum flow system (which is intended to provide a 400 cfs outage flow during outages). GLHA promptly implemented the appropriate measures to respond to the interruption in a timely manner, thus minimizing the duration of the excursion.

GLHA is not aware of any adverse impacts to fish or wildlife resources or water quality in the Penobscot River as the result of this flow disruption, and no additional incidents (safety, dam safety, public safety, security) resulted from this event.

Please feel free to contact me at (207-723-4341, x118) if you have any questions or comments.

Sincerely,

Kevin Bernier

Subject: **Preliminary Comments on the Proposed Study Plan (PSP) for the Ripogenus Project (P-2572) and the Penobscot Mills Project (P-2458)**

Dear Secretary Bose:

The Maine Council of Trout Unlimited ("TU"), Appalachian Mountain Club ("AMC"), American Whitewater ("AW"), Caribou, Chesuncook Lake Camp Owners Association, Chesuncook Dam Camp Owners Association, the Allagash Gateway Campground, and Andre Emerson Cushing Corporation file these comments to address our underlying concerns regarding the current status and direction of the relicensings of the Ripogenus Project (P-2572) and the Penobscot Mills Project (P-2458) being undertaken by Great Lakes Hydro America, LLC for Brookfield Renewable ("Brookfield") or ("Applicant"). Brookfield filed its Proposed Study Plan on November 22, 2021. While each of our organizations intends to file separate comments in response to specific study requests, we are providing these comments to voice our shared concerns regarding the manner in which Brookfield has approached the relicensing process to date.

**Background**

Maine Council of Trout Unlimited represents six local chapters with over 2,000 fisher-conservationists in Maine. The mission of the organization is to bring together diverse interests to care for and recover rivers and streams so our children can experience the joy of wild and native trout and salmon. The entire watershed of the West Branch of the Penobscot is especially important to a great many of our members who enjoy its fishing resources, including the area from McKay Station to Nesowadnehunk Falls, Ripogenus-Chesuncook-Caribou Lake, and the waters below to its confluence with the main stem of the Penobscot River that are greatly affected by the Ripogenus and Penobscot Mills projects.

Since 1876, the Appalachian Mountain Club has promoted the protection, enjoyment, and understanding of the mountains, forests, waters, and trails of the Appalachian region. AMC is the largest conservation and recreation organization in the Northeast with more than 90,000 members, supporters, and advocates, many of whom visit the lands and waters upstream and downstream of the projects for recreation.

American Whitewater is a national non-profit 501(c)(3) river conservation and recreation organization founded in 1954. With approximately 6,000 members and 100 affiliate clubs, representing tens of thousands of whitewater paddlers across the nation, American Whitewater's mission is to protect and restore our nation's whitewater resources and to enhance opportunities to enjoy them safely. Our members are primarily conservation-oriented kayakers and canoeists, many of whom live and/or engage in recreational boating in the New England region within reasonable proximity to the West Branch of the

Penobscot River. American Whitewater has long been involved with the FERC licensed hydropower projects in Maine, including hydropower projects located on the Penobscot, Kennebec, Rapid, and Magalloway rivers, and is party to settlement agreements that provide for whitewater boating opportunities that partially mitigate for project impacts. We highly value the whitewater activities offered by the West Branch.

The Caribou and Chesuncook Lake Camp Owners Association and Chesuncook Dam Camp Owners Association represent the interests of those with property on the shores of these lakes who have been greatly affected by the severe dewatering of the Ripogenus-Chesuncook impoundment in recent years.

Allagash Gateway is a four-season sporting camp located on Ripogenus Lake near the Chesuncook Dam Point Boat Launch. It offers a private boat launch, canoeing, campsites, lodging, guide services, and a small store. During the summer months, Allagash Gateway's clientele is primarily interested in boating and fishing the lakes that make up the Ripogenus impoundment. Operations of the campground have been profoundly impacted over the last few years by the water levels of Ripogenus Lake and Chesuncook Lake.

Andre Emerson Cushing Corporation is the majority landowner in T3 R12 WELS. Approximately 80% of Ripogenus Lake and 20% of Chesuncook Lake are within the boundaries of T3 R12 WELS. William Cushing, a director of Andre Emerson Cushing Corporation, is a year-round resident of T3 R12 WELS, and his home is on Ripogenus Lake.

**The Problem**

Brookfield devotes pages of the Pre-application Document (PAD) to the assertion that: "*GLHA maintains that a full suite of new studies is not needed, that the vast body of information on which today's certifications and licenses are soundly based and should be relied upon for these relicensings. In addition, consistent with the Commission's criteria for study requests, the scope and extent of any new study be focused on addressing specific data gaps necessary to inform the development of license requirements."*[1] The PAD goes on to explain: "*These PM&E measures comprehensively address resource interests specific to the Project areas, as well as the larger river basin. These interests include water quality; management and balancing of flows within and downstream of the West Branch; aquatic and terrestrial resources; whitewater and recreational opportunities; cultural resources; and land management*."[2] The implication is that these measures remain fully adequate when they are not. The PSP states: "*Based on the totality of studies conducted, settlement agreements reached, PM&E measures incorporated, and water quality certifications issued, FERC's 1996 licenses concluded that the Projects are best adapted to serve the public interest. GLHA maintains that nothing has significantly changed that would alter this conclusion."*[3]

These assertions could not be more wrong and started the relicensing off on the wrong foot. A glaring example: The Ripogenus-Chesuncook impoundment has not been fully watered in two years, and the boat launch provided as PM&E has been so far from the waterline for most of the summers so as to be practically unusable, as many photos have clearly shown. The public interest has vastly changed since the last relicensing. Agencies bent over backward to ensure the profitability of the mills in East

[3] PSP, pages 11-12.

Millinocket, the major employer in the area, that were supplied by power the projects provided. If that were not the case, the Use Attainability Analysis (UAA) and the provisions of 38 M.R.S.A. § 464(9-A) would not have allowed so much leeway for project operations, e.g., no minimum drawdown for the Ripogenus-Chesuncook impoundment other than the lowest levels the physical characteristics of Ripogenus Dam allow. Other examples included the dewatered Ripogenus Gorge on the main stem of the West Branch below Ripogenus Dam and 4.5 miles of the main stem below Stone Dam. **It is highly unlikely that these examples would have been permitted under the last relicensings were it not for economic considerations that simply no longer exist.** With the mills closed and the electricity produced by the projects going to the grid and not dramatically affecting the economy of the region, the situation has changed greatly, and that change needs to be acknowledged for the relicensing process to proceed effectively under the ILP. Brookfield should acknowledge this fact or include the request for a socio-economics study submitted by the Penobscot Indian Nation[4] in its Revised Study Plan.

Brookfield is required to provide FERC with information in the PAD and PSP referencing either relevant and recent existing studies or proposing new studies that address a number of subject areas including: Fish and Aquatic Resources, Recreation and Land Use, Aesthetic Resources and Tribal Resources. Instead, Brookfield relies on dated, unavailable, or non-existent studies or directs stakeholders to search for the information themselves at other agencies or on the Internet. Examples: Fisheries Resources - including "*Species life stage composition*"[5] were provided by referencing data some of which is over 30 years old. During the PSP teleconference, Brookfield referred the requirement to the Maine Department of Inland Fisheries and Wildlife. It is not the Department's requirement to provide the information, it is the Applicant's obligation, and the data still has not been fully provided for all projects' reaches except by references to a number of studies of varying ages. Recreation and Land use was nearly ignored, and we fail to understand the relevance of Brookfield's reference to "*Existing shoreline management policies*"[6] for an impoundment that has not been fully watered for two years and where the waterline has generally been hundreds of feet from the boat launch it accesses. There are many recreational amenities not in the project area that are well known and frequently used that will not be considered by forthcoming studies. The accepted information and study standards are simply being ignored.

The key studies are the flow studies proposed by the National Marine Fisheries Service (NMFS); key information is the ten years of operational data requested by the National Marine Fisheries Service (NMFS) There is no USGS flow gauge above the Medway Project nearby to the confluence of the West Branch with the main stem of the Penobscot River. Brookfield has been reluctant to release operational data that would reveal flows. Brookfield clearly has this data and has provided it to FERC Compliance Division on a number of occasions when reporting flow excursions. There was some discussion during the PSP Teleconference of delaying the requirement for a project operations and flow monitoring plan until after the new license is issued. This would make the relicensing process itself nearly meaningless. Over 50 years have passed since the passage of the Clean Water Act. Our nation's waters now run clean but too many still lack the indigenous aquatic organisms due to dams and lack of access to critical habitat. The dams on the West Branch will remain for the foreseeable future. The task of relicensing is to manage the resource most effectively to support all uses including power generation, ecology, recreation and aesthetics. Flow data is essential to the relicensings of both projects. It has been available all along and should have been offered with the PAD. While Brookfield has stated that it will provide

[4] Penobscot Nation letter dated October 12, 2021, RE: Penobscot Mills (P-2458-247) and Ripogenus (P- 2572-133) Notice of Intent, Pre-application document, Scoping document #1 and study requests

[5] Id., page 5.

[6] Id., page 6.

some flow data with the RSP, this will not provide stakeholders with sufficient time to analyze and comment on data that Brookfield has yet to provide.

The Integrated Licensing Process is intended to "s*treamline the Commission's licensing process by providing a predictable, efficient, and timely licensing process that continues to ensure adequate resource protections.*" To date, any reasonable analysis of Brookfield's participation in the Ripogenus - Penobscot Mills relicensing process indicates that Brookfield is attempting to delay and confuse the process by failing to provide the data required by FERC with the PAD, and then rejecting study requests involving the data.

**The Commission's Opportunities**

The FERC process has developed over the years to provide an orderly process leading toward licensing or relicensing of an energy project. 18 CFR § 5.6 clearly defines what information the applicant should provide in the PAD. Instead of providing it, Brookfield referenced studies conducted over 30 years ago and proposed to fill "data" gaps. Stakeholders submitted requests for the information in their PAD comments; Brookfield's response was to concentrate on the study requests and instead of providing the requested information in a usable form, to provide or reference old studies. This is not how relicensings are generally conducted under the ILP, whether or not the relicensing is the first conducted after passage of Electronic Consumers Protection Act (ECPA).

We appreciate FERC staff's recognition that the terms "dry way" and "back channel," used by Brookfield to refer to dewatered sections of the main stem of the West Branch, are inappropriate. We also applaud SD2 as a significant step in the right direction and expanding significantly on the limited scope that Brookfield had proposed. Brookfield's response was to issue a Proposed Study Plan that only accepted three studies as submitted. In a number of cases, studies are rejected that are clearly indicated by the SD2 as within the scope of FERC's planned NEPA analysis, yet Brookfield is not committing to completing studies that will address the data gaps and scope provided by SD2. For example, SD2 identifies that the NEPA analysis will seek to understand the effects of the projects on angling access/opportunities on the project impoundments, yet the PSP provides for no methodology or approach within the recreation study to specifically survey or assess the impact to and quality of angling on the impoundments and this information cannot be ascertained solely through spot counts and a facility assessment. Comparable, SD2 indicates that the NEPA analysis will assess the effects of the projects on angling opportunities for landlocked salmon and brook trout in the riverine reaches, which cannot be adequately assessed using the PSP's methodology which includes only site assessments and spot counts.

Furthermore, in arguing that study requests lack a nexus to project effect, the licensee relies on the *Centralia* decision (*City of Centralia v FERC*, 213 F.3d 742, 749 (D.C. Cir., 2000)) to argue that certain studies are an attempt to search for a problem where there is no evidence that problem exists. The licensee's reliance on *Centralia* is misplaced. That case concerned a post-license study of the need for a tailrace barrier net where there was substantial evidence in the record that the barrier net was unneeded. There the court found that the project effects of the discharge on fish were entirely speculative. Similarly, in *City of Jackson, Ohio*, 105 F.E.R.C. ¶61,136 n.9 (2003), a FERC decision on which the licensee relies, likewise involved a post-license study to assess whether the project was having an adverse effect on fisheries resources. This decision is inapplicable to circumstances such as are present on the West Branch of the Penobscot where the effect of the project on a protected resource is clear and the study is designed to evaluate the extent of that impact so that FERC can complete its NEPA review based on its scoping document. *FPL Energy Maine Hydro, LLC*, 95 F.E.R.C. ¶61,106 n.15 (2001)

and *Allegheny Energy Supply Company, LLC*, 109 F.E.R.C. ¶61,028, 61,117 (2004), also cited by the licensee, likewise involved the need for a license condition requiring a post-license study of project effects on fish. Each of these cases is inapposite to the study requests on the West Branch.

The licensee endeavors to extend the holding in *Centralia* and subsequent FERC decisions to argue against requiring studies *during* the pre-application phase of the Integrated Licensing Process (ILP) to limit the information available to FERC for its NEPA analysis. FERC's nexus requirement in its study criteria was not intended to create a barrier to study of project effects on resources that are within FERC's power to address in a license condition. In effect, the licensee's circular logic would require prior study in order to justify the need for a study while prior study makes the need for a study unnecessary. To meet FERC's nexus criteria, a proposed study need only show that the project has a direct or indirect effect on a non-developmental resource that will be evaluated by FERC as part of its environmental assessment. This Catch-22 scenario was certainly not what Congress intended when the Electric Consumers Protection Act amended the Federal Power Act to require that FERC "shall give equal consideration to the purposes of energy conservation, the protection, mitigation of damage to, and enhancement of, fish and wildlife (including related spawning grounds and habitat), the protection of recreational opportunities, and the preservation of other aspects of environmental quality." 16 U.S.C. § 797(e).

The circumstances surrounding the *Centralia* decision are different from those surrounding the Ripogenus - Penobscot Mills relicensings. Brookfield has applied the phrase "*where evidence of a problem has not been shown"* to a number of study requests. The dewatering large areas of Maine's third largest lake for months at a time, dewatering its most dramatic gorge or a 4.5 mile section further downstream, or abruptly reducing flows from about 2000 cfs to 400 cfs or lower stranding fish and macro-organisms in the process, provides ample evidence that a problem exists.

**Conclusion and Requests**

Accordingly, we ask that:

- FERC require that Brookfield address these comments when evaluating each stakeholders' individual Proposed Study Plan Comments, and offer a Revised Study Plan that will inform the process with current information.
- FERC review the applicant's revised study plan immediately after issuance to ensure that all scope items included in SD2 will be adequately assessed in the proposed studies and that the revised study plan include methodologies that will close all data gaps. Should any gaps continue to exist between the scope of the NEPA analysis and the studies proposed by the applicant, FERC should require the applicant to update the revised study plan, before stakeholders are required to comment on the revised study plan.
- FERC staff consider these comments in making its Study Plan Determination and insist on a suite of studies that will inform the process in accordance with FERC guidelines pursuant to 18 CFR § 5.6 and avoid larger problems later in the relicensing process.
- FERC staff extend the deadline for comments on the Revised Study Plan to 60 days to allow the public to provide additional comments based on operations data and other information provided in the RSP that was not provided with the PSP.

Our organizations appreciate the opportunity to provide these preliminary comments on these important projects and hope that the Commission will act to allow the resource protection agencies to obtain a range of studies that can identify potential harms to the resource and thus enable the Commission to balance project harms and benefits.

# Historical Operations Data Assessment Study Plan

## 1.0 Study Requests

Although there were no formal study requests related to an assessment of historical operations data for the Projects, numerous stakeholders submitted comments requesting that GLHA provide detailed historical operations data. Due to the substantial amount of time needed to develop detailed historical operations data for six developments relative to the larger relicensing schedule, GLHA is proposing to address the stakeholders' information requests through a Historical Operations Data Assessment Study.

## 2.0 Goals and Objectives

The goals and objectives of the proposed study are to compile relevant historic operations data for both Projects to allow stakeholders to better understand historical operations of the Projects and associated water management objectives in support of the relicensing of the Projects.

## 3.0 Resource Management Goals

The West Branch of the Penobscot River in the vicinity of the Projects is managed by the Maine Department of Inland Fisheries & Wildlife (MDIFW) as a combination of warmwater, coolwater, and coldwater fisheries, with a focus on landlocked salmon and brook trout. In addition, the Projects' impoundments and the West Branch between McKay Station and Ambajejus Lake (North Twin impoundment) provide significant recreational resources.

## 4.0 Study Area

The study area consists of each development associated with the Ripogenus and Penobscot Mills Projects.

## 5.0 Background and Existing Information

The Ripogenus and Penobscot Mills Project developments were originally constructed between the late-19th century and mid-20th century to meet the hydromechanical and hydroelectric demands of the Millinocket and East Millinocket Mills, which were constructed in 1900 and 1906, respectively.

The Federal Energy Regulatory Commission (FERC or Commission) issued original licenses for the Ripogenus Project on December 20, 1968, and for the Penobscot Mills Project on October 14, 1968, both of which expired on December 31, 1993. On June 28, 1991, the Commission issued an order amending the licenses to reflect a change in the Licensee's name from Great Northern Paper Company to Great Northern Nekoosa Corporation. On May 8, 1992, the Commission issued an order transferring the licenses from Great Northern Nekoosa Corporation to Great Northern Paper, Inc. The Projects each operated under annual licenses until the new licenses were issued to Great Northern Paper, Inc. on October 22, 1996. On May 19, 2000, the Commission issued an order transferring the licenses from Great Northern Paper, Inc. to GNE, LLC, and on August 26, 2002, FERC issued an order amending the licenses to reflect a change in the Licensee's name from GNE, LLC to Great Lakes Hydro America, LLC (the current Licensee).

The Projects were initially developed to power the paper mills located in Millinocket and East Millinocket. In 2008, the Millinocket paper mill was shuttered and in 2013 the East Millinocket paper mill was shuttered. After the mills were closed, GLHA converted the units from 40 Hertz (used to power the paper mills) to 60 Hertz (used to supply power to the grid), which occurred gradually over time since 2008 due to the significant capital investment associated with the conversion.

## 6.0 Project Nexus

Operation of the Projects influences impoundment elevations for each of the Project developments, as well as downstream riverine flows within and downstream of the Projects.

## 7.0 Methodology

GLHA proposes the following methods for this study:

- GLHA will identify the available, relevant, and accurate operational data for the Projects dating back no further than January 1, 1997, which is less than 3 months after issuance of the Projects' current licenses (October 22, 1996).
- GLHA will process the identified operational data to create graphics as it relates to impoundment elevations and downstream flows.
- GLHA will present the operations data in relation to the applicable license requirements for the Projects.

GLHA believes that the information presented in this study will allow FERC and stakeholders to better understand how the Projects have been operated during the term of the existing licenses in relation to license requirements and other aspects such as changes in operation or use of power. The information produced by this study will also help inform other studies and evaluation of potential impacts from Project operations and associated mitigation strategies, as appropriate.

## 8.0 Schedule

GLHA proposes to perform this study in 2022, with study results provided in the Initial Study Report to be filed with FERC by April 22, 2023.

## 9.0 Level of Effort

The estimated cost for this study as proposed is approximately $60,000.

## 10.0 Deviations from Requested Study

GLHA believes that the proposed study satisfies the requests for operational data by numerous stakeholders.

Re: The Ripogenus Projects P-2572

Great Lakes Hydro America's April 29, 2022 Filing, Articles 402 and 406: Violations not Excursions?

The Licensee's April 29, 2022 filing calls the past winter's low flow event an "excursion" when it was, in fact, a violation of two License Articles; 402 and 406. Extreme low fall and winter flows impacted two salmon year class (fry from 2020 and eggs from 2021 spawning) and aquatic communities. The impact of lost salmon reproduction will be evident in two to four years.

The licensee's April 29, 2022 "after the fact" *salmon spawning and incubation minimum flow excursion* Article 402 notification is not only six months late but additionally, fails to acknowledge the obvious violation of Article 406 of the Ripogenus Project License. Low McKay Station flow events that began September 6, of 2021 (GHHA filing of March 23, 2022) and continued into April, 18 2022. This impacted juvenile landlocked salmon (salmon) habitat in all areas downstream of McKay Station. Article 406 was designed as mitigation. The goal was to produce young-of-the-year salmon in the Holbrook spawning and nursey bypass channel. Article 406 requires a flow of 35 cfs for the period beginning June 1, continuing until October 15. At that time flows are increased to 65 cfs. On September 17, 2021 the licensee photographed the upper section of the Holbrook bypass area. These pictures clearly show a reach with low flow and unsuited to meet goals developed by MeDIFW. This was the first documented violation of Article 406. Flows were further reduced March 4, 2022 (March 9, 2022 filing). The result was the additional loss of salmon fry and parr overwintering in the bypass and downstream reaches. This was in addition to spawning and incubation losses admitted to by the Licensee in its April 29, 2002 filing. In summary, poor flow management resulted in a serious and avoidable violation of Article 406 and the loss of two years classes of salmon; winter kill of fry spawned in 2020 and spawning failure in the fall of 2021

FERC's licensing and compliance process is based on trust. Licensees are required to follow conditions imposed to mitigate private use of a public resource. In this framework the licensee is mandated to self-report any failure, for whatever reason, to comply with the term of its license. As several filings by interested parties in the on-going relicensing have shown, Brookfield does not understand the rules, or worse is willfully ignoring them.

The Licensee wants the public and FERC staff to believe that it had no idea it was required to provide water to the Holbrook by-pass. They simply maintained a pattern of providing water and when it dried up the fish eggs and other habitat for six months it was an excursion from that pattern. A violation for which they show no remorse.

In my opinion, FERC must impose a civil penalty of at least modest proportion, to demonstrate to this licensee that compliance and trust must be introduced to its corporate hydroelectric operations.

Thank you for the opportunity to comment.

**Reference: Study Plan Determination for the Ripogenus Hydroelectric Project and the Penobscot Mills Hydroelectric Project**

Dear Mr. Dorman:

Pursuant to 18 C.F.R. § 5.13(c) of the Commission's regulations, this letter contains the study plan determination for the Ripogenus and Penobscot Mills Hydroelectric Projects (collectively, the "Projects"). The Projects are located on the West Branch of the Penobscot River and Millinocket Stream in Piscataquis and Penobscot Counties, Maine. The determination is based on the study criteria set forth in section 5.9(b) of the Commission's regulations, applicable law, Commission policy and practice, and the record of information.

Background

On November 22, 2021, Great Lakes Hydro America, LLC (GLHA) filed a proposed study plan (PSP) for 12 studies[1] related to water quality, fisheries, recreation, and cultural resources in support of its intent to relicense the Projects.

[1] The PSP lists eight proposed studies. The proposed Water Quality Study includes five component studies/assessments, which we consider separately. Thus, for our purposes, the PSP consists of a total of 12 studies.

GLHA held study plan meetings on December 15 and 16, 2021, to discuss the PSP. Comments on the PSP were filed by the National Marine Fisheries Service (NMFS); the U.S. Fish and Wildlife Service (FWS); the Penobscot Indian Nation; the Maine Department of Environmental Protection (Maine DEP); the Maine Department of Inland Fisheries and Wildlife (Maine DIFW); the Maine Department of Marine Resources (Maine DMR); the Maine Department of Agriculture, Conservation & Forestry - Bureau of Parks and Lands (Maine BPL); the Maine Historic Preservation Commission; American Rivers and Appalachian Mountain Club (collectively, AW/AMC); the Maine Council of Trout Unlimited (Maine TU); the Atlantic Salmon Federation; the Caribou and Chesuncook Lake Camp Owners Association; Edward Spear; and eleven additional members of the public.

GLHA filed a revised study plan (RSP) on March 23, 2022, which included the 12 studies filed in the PSP, and 8 additional studies related to project operations, water quality, aquatic and terrestrial resources, recreation, and aesthetics, for a total of 20 proposed studies. Comments on the RSP were filed by FWS, NMFS, Maine DIFW, Maine DEP, Maine BPL, Maine TU, AW/AMC, Caribou and Chesuncook Lake Camp Owners Association and Chesuncook Dam Camp Owners Associations (collectively, the Camp Owners Associations), the Maine Professional Rafting Outfitters (MEPRO),[2] Edward Spear, and 24 other individual stakeholders.

On April 27, 2022, GLHA filed a response to comments on the RSP.

General Comments

Some comments on the RSP do not directly address study plans. For example, some comments provide additional information, request additional information or clarification from GLHA, or recommend protection, mitigation, and enhancement measures. This determination does not address such comments, but only addresses comments specific to the merits of the proposed studies submitted pursuant to section 5.13 of the Commission's regulations and received thereon.

Study Plan Determination

Of the 20 studies proposed by GLHA, 8 are approved as filed and 12 are approved with staff-recommended modifications. This determination also approves: (1) FWS's request for a Terrestrial, Wildlife, and Botanical Resources Study, with staff-recommended modifications; (2) Maine DEP's and Maine TU's request for a Fish Assemblage Study for the Ripogenus Project, with staff recommended modifications;

[2] MEPRO requests a Carbon Sequestration Study and a Wetted Width Study for the Projects. In both instances, the requests are vague and do not follow the study criteria outlined in section 5.9(b) of the Commission's regulations. Therefore, these two studies are not considered in this Study Plan Determination.

(3) the Penobscot Indian Nation's request for a socioeconomic study, with staff-recommended modifications; and (4) Maine TU's request for a fish stranding study downstream from McKay Station. The determination also denies requests for 13 additional studies recommended by stakeholders (*see* Appendix A). The specific modifications to the study plan, and the bases for modifying GLHA's study plan, as well as modifying, adopting, or not adopting requested studies, are discussed in Appendix B. Although Commission staff reviewed all comments and considered all study plan criteria in section 5.9 of the Commission's regulations, only the specific study criteria particularly relevant to the determination are referenced in Appendix B.

Study issues raised in comments on the PSP, but not again in comments on the RSP, are considered to be resolved, and, therefore, those issues are not discussed in this determination. Unless otherwise indicated, all components of the approved studies not modified in this determination must be completed as described in the RSP. Pursuant to section 5.15(c)(1) of the Commission's regulations, the initial study report for all studies in the approved study plan must be filed by May 13, 2023.

Nothing in this study plan determination is intended, in any way, to limit any agency's proper exercise of its independent statutory authority to require additional studies. In addition, GLHA may choose to conduct any study not specifically required herein that it feels would add pertinent information to the record.

If you have any questions, please contact Allan Creamer at (202) 502-8365, or at allan.creamer@ferc.gov.

Sincerely,

for
Terry L. Turpin
Director
Office of Energy Projects

# APPENDIX B

# STAFF RECOMMENDATIONS ON PROPOSED AND REQUESTED STUDIES

## I. Requests for Proposed Study Plan Modifications and Requests for Additional Studies

### Study 1. Historic Operations Data Assessment

Applicant's Proposed Study

GLHA's stated goal of this study is to compile relevant "historic" operations data for each development of the Ripogenus Project and the Penobscot Mills Project (collectively, the Projects) to allow stakeholders to better understand historic operations. GLHA would identify available operational data for the Projects dating no further back than January 1, 1997, which was shortly after the current licenses were issued on October 22, 1996. For each development, GLHA would develop graphics of impoundment elevations and downstream flows. GLHA states that they would use the data to evaluate historic operations in relation to current license requirements. The study would be initiated in 2022, with study results provided in the initial study report (ISR) to be filed by May 13, 2023.

Comments on the Study

None.

Discussion and Staff's Recommendations

The current licenses for the Projects allow for flexibility in operations, particularly with respect to reservoir elevation limits (e.g., the Ripogenus impoundment has no regulatory limit on its drawdown). This flexibility, in combination with the shutdown of the Millinocket Paper Mill in 2008, and East Millinocket Paper Mill in 2013, warrants a review of the Projects' operations throughout the current license terms to identify the potential range of operations under current conditions. This information may also be useful in identifying alternative reservoir operating levels to be evaluated in GLHA's proposed Operations Model. The proposed Historic Operations Data Assessment should identify flow releases, reservoir elevation ranges, and generation; identify the ranges of these parameters during the current license term; and evaluate how these parameters may have changed during the current license terms.

GLHA's proposed study does not identify what "relevant historic operations data" would be included in this assessment, or the timestep for flow data. In the Revised Study

Plan (RSP), GLHA provided daily minimum, maximum, and average flow and elevation data for the Projects' developments for the 10-year period from January 1, 2010, through September 30, 2021. The RSP indicates that this information would also be provided for an additional 13 years, as far back as 1997. Daily average flow and elevation data would be sufficient to inform alternative operating scenarios to be evaluated in the Operations Model [section 5.9(b)(6)]. Therefore, we recommend that GLHA's proposed assessment be modified to include the additional 13 years (i.e., back to 1997) of daily minimum, maximum, and average flow and elevation data as available. The data should be provided in excel format and summarized graphically.

We have compiled average annual generation data for the Projects for the 24-year period from 1997 through 2021.[3] This information is attached in Appendix C, and because there would be no cost to GLHA [section 5.9(b)(7)], we recommend it also be included in the ISR.

The ILP regulations provide a procedure for modifying the study plan, as necessary, based in part, on the results of the first year of studies [sections 5.15 (d) and 5/15(e)]. Should GLHA's review and assessment of historical operations data prove insufficient in describing the Projects' historical operations, and data gaps in describing the Projects' operations remain, additional studies to obtain that information could be considered after ISR filing.

**Study 2. Operations Model**

Applicant's Proposed Study

GLHA proposes to develop a project operations model to simulate elevations for each of the Projects' impoundments under various operating constraints (i.e., minimum flows, various starting impoundment levels, and hydrology). GLHA proposes to develop the model using Computer Hydro Electric Operations and Planning Software (CHEOPS). CHEOPS models can be used to evaluate potential operating alternatives based on historic hydrology for the Projects. GLHA indicates that the model would support an evaluation of alternative operations at an hourly time step. Moreover, the model would estimate the degree to which different flow releases could be maintained at different starting elevations in the impoundments. The model would be developed in 2022, and a report describing the information and process used to develop the model provided in the ISR.

[3] Our preliminary evaluation of this data suggests that annual generation has been primarily based on flow availability (i.e., whether it was a wet/average/dry water year). No obvious changes in generation were identified after the Millinocket and East Millinocket Mills shut down.

Comments on the Study

In comments on the Proposed Study Plan (PSP) and RSP, multiple stakeholders request that GLHA provide hourly operations data at each development to better understand how the Projects operate.

Discussion and Staff's Recommendations

As a general matter, GLHA's proposed Operations Model would assist our assessment and consideration of potential operational alternatives under any new licenses for the Projects. However, the RSP lacks sufficient detail regarding how the input data would be determined or how the model would be calibrated. Additionally, the RSP does not identify opportunities for stakeholders to engage in the development, evaluation, specification of model runs, or review of model runs. Because this information is needed to inform the need for, and development of, license requirements [section 5.9(b)(5)], and adding these elements to the Operations Model can be done with little cost to GLHA [section 5.9(b)(7)], we recommend that the study plan for the Operations Model be revised to include these measures, as well as a detailed schedule for consulting with the stakeholders and responding to their concerns as the model is developed, and during the alternative development/evaluation process.

To facilitate our and the stakeholder's review and evaluation of the model's development, assumptions, and results [section 5.9(b)(6)], we recommend that GLHA include the model inputs, outputs, and assumptions with the ISR, or if that is technically infeasible, on a protected, cloud-based server with access granted to relicensing participants upon request.

Multiple stakeholders request hourly operations data for each of the Projects' developments. The RSP indicates that the model would accommodate an hourly time step, but provides no information on the details of the input data that would be used in the model. Understanding the inter-relationship between hourly project operations and the associated effects on environmental and developmental resources, is necessary to inform the development of license requirements [section 5.9(b)(5)].

We agree that an hourly timestep for operations data is appropriate, but recognize the extensive amount of data needed to include the entire period of record since the last license was issued. To minimize what would be an extensive amount of data [section 5.9(b)(7)], we recommend hourly data be used for representative years that captures dry flow-year operation, average flow-year operation, and wet flow-year operation. Table 1-1 in the RSP describes average annual flows and water year classification at the Projects for years 2001 through 2021. This information could be helpful in selecting

representative years for model runs; we recommend, at a minimum, one dry flow-year, one average flow-year, and one wet flow-year be modeled.

The ILP regulations provide a procedure for modifying the study plan, as necessary, based in part, on the results of the first year of studies [sections 5.15 (d) and 5/15(e)]. Additional water years could be considered after ISR filing.

**Study 5. Fish Stranding Study**

Requested Study

In its comments on the PSP, the Maine Council of Trout Unlimited (Maine TU) requests that GLHA conduct a Fish Stranding Study in the West Branch of the Penobscot River (West Branch) downstream from McKay Station.[4] Maine TU indicates that fish and invertebrate strandings have been documented downstream from McKay Station during low flow excursions that occur during generator shutdowns. Maine TU contends that these strandings may represent a source of fish mortality and injury. The goal of Maine TU's requested study is to determine the extent and harm of stranding pools that occur downstream from the McKay Station discharge to Nesowadnehunk Falls, particularly during 400-cubic-feet-per-second (cfs) generator trip events.[5] The study requested by Maine TU would involve a review of operational data to determine the range of flows at which generator trips at the McKay Station are likely to occur and field surveys to examine potential stranding sites and visually document any stranded fish.

[4] Maine TU requested a Flow Excursion Study for the Ripogenus Project to evaluate: (1) the consistency of flows from Ripogenus Dam as they relate to the project's current minimum flow requirements; and (2) the impacts of the 400-cfs generator outage flow on aquatic organisms. In the PSP, GLHA indicates that the proposed Historical Operations Data Assessment would address the questions regarding deviations from minimum flow requirements. In their comments on the PSP, Maine TU states that GLHA did not address the second component of their study request, evaluating the effects of the 400-cfs generator outage flow on aquatic organisms, and proposed a Fish Stranding Study. Based on Maine TU's comments on the PSP and RSP, we assume that the Fish Stranding Study request replaced their original Ripogenous Flow Excursion Study request.

[5] A minimum outage flow of 400 cfs (hourly average) is provided downstream of McKay Station in the event of an unplanned station trip or emergency requiring station shutdown. This outage flow is maintained until GLHA is able to restore minimum flows required under the current license.

Comments on the Requested Study

In its comments on the RSP, GLHA states that it does not propose to conduct Maine TU's requested Fish Stranding Study. GLHA indicates that information collected and reported from other proposed studies, such as the Historical Operations Data Assessment, will detail how the Ripogenus Project has been operated, including flows provided by McKay Station. Additionally, GLHA indicates that the fieldwork performed in the West Branch downstream from McKay Station for other studies would provide additional information regarding flows in the West Branch in relation to aquatic organisms.

Reply Comments

In comments on the RSP, Maine TU reiterated its request for a Fish Stranding Study, indicating that several fish stranding events have been documented downstream from McKay Station. Maine TU states that GLHA has the ability to eliminate strandings and provide "fish friendly" flows. Maine TU asserts that the information needed to improve conditions for fish health and survival can be provided through a combination of: (1) analysis of hourly operational data; (2) the flow studies requested by the National Maine Fisheries Service (NMFS); (3) the Ramping Rate Study proposed by Edward Spear; and (4) the Fish Stranding Study proposed by Maine TU.

Discussion and Staff's Recommendation

Rapid changes in flow and decreases in water surface elevation can increase the risk of fish and invertebrate stranding which may be stressful and/or lethal for aquatic organisms. While GLHA's proposed Historic Operations Data Assessment would help identify how the Ripogenus Project has been operated, it is unclear whether GLHA proposes to evaluate the conditions that could lead to low flows downstream of McKay Station. Further it is unclear how or what proposed studies would examine the potential effects of reduced flows and flow change rates on downstream fish and aquatic invertebrates.

Reviewing operational data would help to identify specific conditions that lead to generator shutdowns and any resulting low flows. Accompanying field surveys, developed in consultation with Maine TU and Maine DIFW, would provide a mechanism to evaluate the potential for, and magnitude of, fish and invertebrate stranding during generator shutdowns. Collectively, these results could inform the development of license requirements for emergency minimum flows and the rate at which downstream flows are increased or decreased, if necessary [section 5.9(b)(5)]. The potential effects of reduced flows and flow fluctuations are likely to extend, at a minimum, to the nearest large, downstream pool. Therefore, we recommend GLHA conduct the Fish Stranding Study

requested by Maine TU, through the area from McKay Station downstream to Nesowadnehunk Falls.

**Studies 6 and 8. Impoundment Trophic State Study and Downstream Water Temperature and Dissolved Oxygen Study**

Applicant's Proposed Studies

As a component of the Water Quality Study, GLHA proposes to conduct an Impoundment Trophic State Study and a Downstream Water Temperature and Dissolved Oxygen (DO) Study for the Ripogenus Project. GLHA's goal for the studies is to collect data sufficient to evaluate whether water temperature, DO, and other water quality parameters (e.g., total phosphorus, chlorophyll-a) are at levels consistent with those specified by applicable Maine water quality standards in the Ripogenus impoundment, the Upper Gorge (bypassed reach), and McKay Station tailrace.

As part of the Impoundment Trophic State Study, GLHA proposes to collect vertical profiles of water temperature and DO at the deepest areas of the six basins composing the Ripogenus impoundment using a handheld YSI ProSolo meter (or similar device). GLHA also proposes to monitor water temperature and DO in the Upper Gorge and the West Branch downstream from McKay Station with Onset HOBO data loggers (or similar devices). The data loggers would be programmed to continuously measure water temperature and DO once per hour through the low-flow, high-temperature period of July through August.

Comments on the Study

In his comments on the RSP, Edward Spear states that GLHA has not collected data necessary to review a Maine Department of Fisheries and Wildlife (Maine DIFW) recommendation that flows into the Upper Gorge be released from a deep gate, to provide cool water for landlocked salmon in the West Branch during the warm summer months, July and August. Mr. Spear recommends that GLHA place a recording thermometer[6] at a depth of 1-2 meters (or 3.3 to 6.6 feet) in the Ripogenus impoundment to collect water temperature data sufficient to characterize the differences among water surface, low-level, and mixed releases. This data would also be used to identify and assess methods (deep gate, siphon, etc.) to cool Upper Gorge summer flows.

Discussion and Staff's Recommendation

[6] For purposes of this discussion, we assume that Mr. Spear's proposed thermometer would be a continuous recording device placed in the Ripogenus impoundment.

GLHA is proposing to collect vertical profiles of water temperature at the deepest location in each of the basins composing the Ripogenus impoundment, including a station located in Ripogenus Lake just upstream from Ripogenus Dam. This effort, coupled with GLHA's proposed monitoring of water temperature in the Upper Gorge, both collected on a bi-monthly basis, should be sufficient to determine the effect of release location at Ripogenus Dam on the water temperature of flows released to the Upper Gorge [section 5.9(b)(6)] in a more cost-effective way [section 5.9(b)(7)], and in a broader spatial context than using a continuous recording device at a single location as recommended by Mr. Spear. Therefore, we do not recommend Mr. Spear's requested modification to GLHA proposed Impoundment Trophic State Assessment and Downstream Temperature and Dissolved Oxygen Assessment for the Ripogenus Project.

**Studies 7 and 13. Impoundment Aquatic Habitat Assessment and Fish Assemblage Study**

Applicant's Proposed Study

GLHA proposes to conduct an Impoundment Aquatic Habitat Assessment at the Projects, which would include littoral zone, macroinvertebrate, and fisheries surveys at the Ripogenus Project. GLHA's study goal is to document whether or not existing lake level management supports native species of fish and the structure and function of a healthy resident fish community. GLHA's proposed assessment would involve reviewing, compiling, and describing existing data, as well as anecdotal information collected from the Ripogenus impoundment by Maine DIFW and other organizations.

The issues to be addressed in GLHA's proposed study are similar to the issues addressed in fish assemblage study requests by the Maine Department of Environmental Protection (Maine DEP) and Maine TU, particularly for the Ripogenus Project. Therefore, our analysis of GLHA's Impoundment Aquatic Habitat Assessment is considered as part of our analysis of the requests for Fish Assemblage Studies, as discussed below.

Requested Study

In its study request, Maine DEP recommends a Fish Assemblage Study for the Ripogenus impoundment. The objective of Maine DEP's study is to determine if the Ripogenus impoundment "meets" Maine Water Quality Standards, including that the existing impounded waters are able to support all species of fish indigenous to those waters, to demonstrate, in part, attainment of the designated use of habitat for fish and other aquatic organisms. Maine DEP provides no methodology for its requested fish assemblage study, but instead requires that GLHA implement established study protocols used successfully throughout Maine by GLHA and others.

Maine TU requests that GLHA conduct a Fish Assemblage Study at each impoundment and riverine reach in the Projects' areas. Maine TU's goal for the study is to document the current fisheries assemblage in the Projects' waters for comparison with past studies. Maine TU's recommended study would involve gill netting, which it indicates is a standard, passive fish sampling method used to collect baseline fisheries data. Maine TU states that the existing information is over 40 years old, and that species composition may have changed over this time period due to: (1) changes in project operations (e.g., the magnitude or duration of impoundment drawdowns that limit the amount of littoral habitat and deep, oxygenated water available in the impoundments); (2) the spread of non-native, invasive fish species; and (3) climate change.

Comments on the Requested Study

In the RSP, GLHA does not propose to conduct Maine TU's requested Fish Assemblage Study, particularly the field sampling component. GLHA states that known information is adequate to characterize existing fish resources in the West Branch. GLHA notes that fish assemblage studies are not always required as part of relicensing a hydropower project. GLHA also states that there is no evidence that operation of the Projects contributes to the spread of non-native, invasive fish species. Finally, GLHA states that the use of gill netting as a method is not an appropriate technique to use in this instance, noting that gill netting is a passive technique that relies on fish movement and is affected by the mesh size of the net, so it would be highly selective in the size and type of fish sampled.

Reply Comments

In its comments on the RSP, Maine DEP states that: (1) the existing information would not be sufficient to demonstrate that the Projects[7] are currently "meeting" water quality standards; (2) the results of a Fish Assemblage Study would inform potential conditions that the Maine DEP could require in any water quality certificate issued for the Projects; and (3) Maine DEP does not provide specific methods for the study in its request because this type of study is commonly conducted in many Commission relicensing proceedings.

Maine TU requests that all reaches of the West Branch that are affected by the Projects (10 in total) be sampled, including the Ripogenus impoundment and the West Branch downstream from Ripogenus Dam and McKay Station, Millinocket Lake Storage

[7] Maine DEP's initial study request was for a Fish Assemblage Study in the Ripogenus impoundment. The agency's comments on the RSP suggests an expanded scope for the study, which would include all waters affected by the Projects.

Dam impoundment and Millinocket Stream, the North Twin impoundment and tailwater, the Millinocket impoundment and tailwater, the West Branch downstream from Stone Dam, the Dolby impoundment and tailwater, and the East Millinocket impoundment and tailwater. While Maine TU agrees that studies do not need to be duplicated, it states that GLHA has not provided a compilation of the fish assemblage studies that it claims currently exists.[8] Maine TU requests that GLHA compile information from all existing fish assemblage studies that have been conducted for the Projects and that GLHA assess this data for data gaps. Based on the outcome of the compilation of existing information, a decision regarding the need for new fish assemblage studies could be made.

Edward Spear states that 40-year-old data collected during a period of relatively stable flows has no value when (a) current operation involves peaking, and (b) lake level management has changed. Mr. Spear indicates that trap netting, electrofishing, and hydroacoustics, along with minnow traps, could provide the necessary information. For the Ripogenus impoundment rainbow smelt population, he suggests specifically that trawls, tows, hydroacoustics, and fine mesh vertical gill nets could be used. Mr. Spear also indicates that lake whitefish should be part of the fish assemblage assessment.

Discussion and Staff's Recommendations

With regard to the Penobscot Mills Project, there have likely been changes to the fish populations and communities in the project area since the studies were conducted about 40 years ago due to changes in Maine DIFW's fisheries management focus and species introductions (e.g., smallmouth bass). While the Preliminary Application Document (PAD) contains some fisheries information for the Penobscot Mills Project area, it appears that a full compilation of the fish assemblage studies conducted during the current license term has not been completed. Additional existing information sources include, at a minimum, recent creel survey data for the West Branch watershed. Therefore, we recommend that GLHA: (1) compile the information from all fish assemblage studies in the Penobscot Mills Project area that have been conducted during the current license term; and (2) assess the information for any data gaps in the fisheries information. The compilation of existing fish surveys and associated assessment should be a component of a Fish Assemblage Study Report, as described below, and filed as part of the ISR.

[8] In its response in the RSP to Edward Spear's request for a creel survey, GLHA indicates that Maine DIFW conducts creel surveys in the West Branch watershed, including in the Ripogenus Project area. GLHA, as part of the fisheries assessment for the Water Quality Study, proposes to "compile and synthesize fisheries data for the Ripogenus Project Area, including any recent creel survey data that may not have been discovered during PAD development."

Although we do not recommend fish assemblage studies for the Penobscot Mills Project, at this time, the ILP regulations provide a procedure for modifying the study plan, as necessary, based in part, on the results of the first year of studies [sections 5.15 (d) and 5/15(e)]. Therefore, if GLHA's compilation of fish assemblage studies for the Penobscot Mills Project proves insufficient for achieving the goal of sufficiently describing the existing fishery, and important data gaps in the fisheries information for the project are identified, additional studies to obtain that information could be considered after ISR filing.

Regarding the Ripogenus Project, there have likely been changes to the fish populations and communities in the project area since studies were conducted about 40 years ago due to changes in project operation, which would render those study results insufficient [section 5.9(b)(4)]. Therefore, we recommend that GLHA conduct a Fish Assemblage Study for the Ripogenus Project that covers all of the sub-basins of the Ripogenus impoundment, the Upper Gorge, and the West Branch downstream to Nesowadnehunk Falls (*see* above discussion for the Fish Stranding Study). Our recommended study for the Ripogenus Project includes:

- Conducting fish assemblage sampling, using electrofishing surveys, as well as other established methods (e.g., trawls, trap/fyke nets). Sampling should occur in the spring, summer, and fall to collect resident rainbow smelt, upstream and downstream migrating American eels (eels), and annual juvenile fish production. GLHA should establish sampling locations and final methods in consultation with the Maine DIFW, Maine DEP, and the U.S. Fish and Wildlife Service (FWS), to ensure that the sites represent the range of habitat types within the study area.

- Identifying to species and counting all fish collected and weighing and measuring a subsample of those fish; measuring eye diameters of captured eels for use in the evaluating eel phase; assessing fish condition; recording the habitat type and substrate of each sampling location; and recording in-situ water quality conditions [water temperature, DO, pH, and conductivity].

- Preparing a Fish Assemblage Study Report, including a summary of the data; tabular listings of fish species collected by sampling location; fish lengths, weights, and condition factors; and habitat and water quality conditions. Reporting specific information on eel population characteristics, such as timing, size, and abundance of upstream and potential downstream migrants.

- Including all data used to develop the report (including date and time of collection) in an appendix, and filing the report and appendix as part of the ISR.

We do not recommend Maine TU's approach of using gill netting for fish assemblage sampling. While this method of capturing fish is an accepted practice in the

scientific community and would provide some consistency with past methods, gill netting is a passive sampling technique, and as such, it would most likely provide only limited presence/absence data on a subset of the fish species that occupy the Ripogenus impoundment and other project-affected reaches of the West Branch [section 5.9(b)(6)]. Additionally, gill netting is typically lethal to the sampled fish, because by design fish are entangled in the nets by their gills.[9] Therefore, there is risk of harming populations of cold-water fish, which is the primary fishery in the project area. Though this information might address Maine TU's goal of sampling to compare new data with old, less lethal methods that target a broader range of fish species are available to meet the study goals, as noted above.

Our recommendation regarding the Fish Assemblage Study incorporates the issues that GLHA proposed to address with its Impoundment Aquatic Habitat Assessment Study for the Ripogenus Project, specifically the Fisheries Assessment. Therefore, a separate data collection effort for the Fisheries Assessment, as proposed by GLHA, is unnecessary.

**Study 10. Benthic Macroinvertebrate Assessment**

Applicant's Proposed Study

As a component of the proposed Water Quality Study, GLHA proposes to conduct a Benthic Macroinvertebrate Assessment to determine the composition of the benthic macroinvertebrate community within the Upper Gorge and the West Branch to about 1,000 feet downstream from McKay Station. The objective of GLHA's study is to evaluate whether aquatic life criteria are attained under existing operations. GLHA would use wading or snorkeling to assess the two reaches and identify suitable sampling locations. GLHA would establish one monitoring station with three replicate samplers (e.g., rock basket or bag) in the Upper Gorge and one station with three replicate samplers downstream from McKay Station. Samplers would be deployed and left in the river to colonize for approximately 28 ± 4 days between July 1 and September 30.

Comments on the Study

In his comments on the RSP, Edward Spear states that GLHA's proposed study is not consistent with the Maine DIFW's study request.[10] In particular, Mr. Spear explains

[9] RSP at 6-16.

[10] We assume that where Mr. Spear cites to GLHA's proposed Riverine Aquatic Habitat Assessment in his comments pertaining to macroinvertebrate sampling at the Ripogenus Project, he intends to refer to GLHA's proposed Benthic Macroinvertebrate

that GLHA is proposing reduced sampling effort, and that GLHA would only sample at one location downstream from McKay Station. Mr. Spear states that the one location downstream from McKay Station is not representative of 20-plus miles of the West Branch downstream from the Ripogenus Project.

Discussion and Staff's Recommendation

Regarding the details of the study methodology, GLHA proposes to use sampling procedures for benthic macroinvertebrates that are consistent with Maine DEP's *Methods for Biological Sampling and Analysis of Maine's Rivers and Streams* (Davies and Tsomides, 2014), which identifies field and laboratory methods, exposure periods, preservation techniques, statistical decision models, quality control, and reporting requirements. Maine DIFW, in its comments on the RSP, states that its requested macroinvertebrate study is "satisfied by the proposed Water Quality Study" filed by GLHA with its RSP.

Regarding the representativeness of GLHA's sampling location in the West Branch downstream from the Ripogenus Project, channel shape and habitat conditions in the West Branch may be different than those in the McKay Station tailrace [section 5.9(b)(5)]. For example, velocities in the McKay Station tailrace (within 1,000 feet downstream from McKay Station) may be higher than in the downstream river reaches, which would result in different substates in the tailrace than in the river further downstream. Adding additional downstream monitoring sites [section 5.9(b)(6)] would provide information necessary to address the effects of project operation on macroinvertebrates, and would not add significantly to the cost of study [section 5.9(b)(7)]. Therefore, we recommend that GLHA, in consultation with the Maine DIFW and Maine DEP, identify and sample two additional locations in the West Branch downstream to Nesowadnehunk Falls (*see* above discussion for the Fish Stranding Study), consistent with the macroinvertebrate sampling protocol being used for the Upper Gorge.

**Study 14. Instream Flow and Habitat Assessment of the West Branch Downstream of Stone Dam Study**

Applicant's Proposed Study

GLHA proposes to conduct an Instream Flow and Habitat Assessment of the West Branch Downstream of Stone Dam Study. The goal of the study is to assess the relationship between flow and aquatic habitat in the West Branch downstream from Stone

---

Assessment, which describes the protocol for sampling macroinvertebrates downstream from Ripogenus Dam.

Dam using a standard and accepted methodology, such as the Instream Flow Incremental Methodology (IFIM). The specific objectives of the study include: (1) assessing the relationship between flow and aquatic habitat for brook trout and landlocked salmon in the West Branch downstream from Stone Dam; (2) assessing the effects of current Penobscot Mills Project operation, including minimum flows, on the potential to support a coldwater fishery in the West Branch between Stone Dam and Grand Falls; and (3) evaluating potential alternative minimum flows in the West Branch downstream from Stone Dam to support a seasonal coldwater sport fishery.

GLHA proposes to use the 1989 IFIM Study and Physical Habitat Simulation (PHABSIM) model data to analyze habitat suitability associated with the existing minimum flows, as well as alternative minimum flows. Modeling would be conducted using standard procedures described by Bovee (1982) and Bovee *et al.* (1998). The focus of the flow-habitat modeling would be the adult life stage of landlocked salmon and brook trout. The prior IFIM Study included hydraulic data collected at 12-14 transects, and modeled mesohabitat features such as rapids and runs at two study sites, each representing a range of channel slopes, widths, and cover conditions observed in the West Branch. The flows simulated in the model would range from 3 to 2,000 cfs. GLHA would evaluate minimum flows in the West Branch downstream from Stone Dam in collaboration with a study team including Maine DIFW, Maine DEP, and other interested stakeholders. The study team would review the existing PHABSIM model and provide input regarding suitability criteria for adult brook trout, macrohabitat[11] and mesohabitat factors, increments of flow to be modeled, and other technical details.

Comments on the Study

In his comments on the RSP, Edward Spear requests that benthic macroinvertebrates be included in the list of aquatic organisms to be evaluated as part of the flow study. Mr. Spear specifically recommends the use of hydropsyschidae caddisflies. In addition, Mr. Spear requests that all life stages of salmon be included in the modeling effort. Finally, Mr. Spear requests to be part of the study process.

Discussion and Staff's Recommendation

Landlocked salmon in the West Branch drainage are primarily of self-sustaining origin; thus, life stages other than the adult life stage (e.g., larval and juvenile salmon) likely depend upon habitat in this reach of the West Branch. Flow releases from Stone Dam could influence aquatic habitat suitability within the channel for both salmon and brook trout. Yet, little is known about the suitability of the West Branch downstream

[11] Macrohabitat includes water quality, such as temperature in the stream, local meteorological conditions, stream network configuration, and the flow regime.

from Stone Dam, at existing and alternative flows, to support all life stages of salmon and their food source [section 5.9(b)(4)]. Stanley and Trial (the latter of Maine DIFW) issued the publication, *Habitat suitability index models: nonmigratory freshwater life stages of Atlantic salmon*, in 1995, as a third-generation report on habitat suitability indices (HIS) for landlocked salmon. HSI models are readily available for brook trout life stages, as well. Thus, HSI curves for different life stages of landlocked salmon and brook trout can be applied to the West Branch habitat characteristics to analyze habitat quality for those species and life stages.

Even less is known about the forage base for landlocked salmon and brook trout in the West Branch. hydropsychidae, referred to by Mr. Spear, is a family of omnivorous caddisflies whose larvae feed and grow in streams and rivers by spinning nets out of which they gather particles of edible material drifting by from upstream. They are a common food source for fish in both warm and coldwater streams (McCafferty, 1983). The habitat needs of hydropsychidae can also be applied to the West Branch habitat characteristics to analyze habitat quality for those larvae. While the HSI curves for hydropsychidae may not be as readily available, there is broad literature on the caddisfly family, including some HSI values, that can support a similar, if not equivalent, analysis to what should be achievable for the fish.

In the list of species/life stages to be evaluated as part of the study, GLHA does not include macroinvertebrates or other life stages of salmon that are likely to inhabit the West Branch. Adding hydropsychidae and other life stages of landlocked salmon to the study is important, because: (1) hydropsychidae is a key forage item for fish in the West Branch; and (2) the landlocked salmon fishery is the premier fishery in the West Branch [section 5.9(b)(6)]. Because (a) the cost of adding hydropsychidae and other life stages of landlocked salmon to the study design would likely be small (because existing information can be used) [section (b)(7)], and (b) the information that would be derived from adding hydropsychidae caddisflies and multiple life stages of Atlantic salmon could assist our understanding the effects of flow releases on the cold-water fishery in the West Branch, we recommend GLHA's proposed Instream Flow and Habitat Assessment of the West Branch Downstream of Stone Dam Study be expanded. Specifically, we recommend that hydropsychidae and other life stages of landlocked Atlantic salmon be evaluated as part of the IFIM modeling effort.[12]

With regard to Mr. Spear's request to be part of the study process, GLHA proposes to evaluate minimum flows in the West Branch downstream from Stone Dam in

[12] The intent of our recommendation is that GLHA make a good faith effort to mine existing suitability information for hydropsychidae and attempt to develop the HSI information based on that existing data. It is not our intent at this time that GLHA be required to conduct field studies to develop the hydropsychidae HSI information.

collaboration with a study team that includes state agencies with resource management responsibilities (i.e., Maine DIFW and Maine DEP), as well as interested stakeholders. Maine DIFW and Maine DEP have sufficient expertise to review the existing PHABSIM model and provide input regarding suitability criteria for the list of species to be evaluated. Therefore, we do not recommend that GLHA's proposed study plan, with specific regard to consultation, be modified as requested by Mr. Spear.

**Study 15. North Twin Impoundment Tributary Access Study**

Applicant's Proposed Study

GLHA proposes to conduct a North Twin Impoundment Tributary Access Study. GLHA's goal for the study is to assess connectivity and spawning conditions for landlocked salmon in tributaries to the North Twin impoundment, and determine if there are barriers to movements into the tributaries exposed during drawdowns of the North Twin impoundment. The specific objectives are to: (1) identify tributaries to the North Twin impoundment that are used by landlocked salmon for spawning or that have habitat suitable for spawning; (2) survey the identified tributary streams and identify potential fish passage barriers both natural and project-related near their confluence with the North Twin impoundment; (3) document evidence of spawning (e.g., spawning behavior and redd formation); and (4) evaluate the effects of the typical seasonal impoundment fluctuation on tributary access by landlocked salmon during critical life stage.

The preliminary list of tributaries GLHA would survey includes the West Branch upstream of the Ripogenus impoundment, Nahmakanta Stream, Partridge Brook, and Jo Mary Stream. The final list of tributaries, however, would be developed in consultation with Maine DIFW. The mouth of the identified tributaries would be: (1) assessed for potential barriers to adult landlocked salmon movement (e.g., ledge drops, debris jams, and wide shallow channel reaches); and (2) surveyed to obtain slope and channel width elevations (via optical survey) during the spring or early summer with full, or nearly full, impoundment conditions. The same tributaries would be assessed and surveyed again in the fall spawning period under seasonal drawdown conditions. Water depths in the shallowest channel zone, and minimum wetted widths, would be surveyed and recorded along the longitudinal axis of each stream, and restrictions would be photographed and geolocated using a Global Positioning System (GPS) device. GLHA would determine stream flow at the time of the survey, and document impoundment elevation. Finally, GLHA would examine the stream reach immediately above the high-water mark (i.e., within the first 328 feet) in each tributary to identify potential spawning habitat and/or evidence of redd construction. This information would be documented in field notes, and locations would be photographed and located with GPS.

Comments on the Study

In its comments on the RSP, Maine DIFW states that it continues to recommend a Landlocked Salmon Radiotelemetry Study for the North Twin impoundment that it requested in its October 8, 2021 study request, and in its February 22, 2022 comments on the PSP. Maine DIFW's goals for the study are to: (1) track seasonal movements and behaviors of landlocked salmon (within and between the five connected lakes) via radiotelemetry; (2) determine the effects of annual project drawdown on the movement and behaviors of landlocked salmon within the North Twin impoundment; and (3) identify landlocked salmon spawning areas within the North Twin impoundment.

Maine DIFW states that the effects of Penobscot Mills Project operation on landlocked salmon spawning movement and behavior, as well as selection of spawning tributaries, in the North Twin impoundment is unknown. Maine DIFW argues that GLHA's proposed study, without radiotelemetry, would not identify spawning activity within slack water areas of the North Twin impoundment. It also would not detect any potential movement downstream out of the North Twin impoundment (via the North Twin powerhouse or dam) during the fall spawning period. Maine DIFW indicates that this information would help identify potential downstream salmon movement and assess the effectiveness of the North Twin fishway to pass salmon back upstream into the impoundment after spawning.

In his comments on the RSP, Edward Spear states that he supports Maine DIFW's request for a Landlocked Salmon Radiotelemetry Study for the North Twin impoundment. Mr. Spear states that it is the only method to determine potential project effects on salmon movement, access to spawning areas, as well as spawning timing and success. Mr. Spear states that there are only two North Twin impoundment tributaries, with a possible third, that have the flow and size capable of supporting significant salmon reproduction. Finally, Mr. Spear states that collecting enough salmon suitable for radio-tagging would be relatively simple, and radio tracking would produce thousands of data points over the 4- to 8-week pre-spawning and spawning periods.

In the RSP, GLHA states that a Radiotelemetry Study is not necessary to document the timing of spawning, as the timing of landlocked salmon spawning is reasonably well known. The intent of the study is to document use of, and access to, tributaries of the North Twin impoundment during spawning season. GLHA asserts that, while tracking seasonal movements of salmon via radiotelemetry and collecting landlocked salmon population dynamics data would be useful fishery management information, it is not necessary to assess the effects of project operation on landlocked salmon spawning.

Discussion and Staff's Recommendations

Annual drawdowns of about 12 feet begin on October 15 and continue to the spring (PAD at page 4-48). Therefore, the drawdown overlaps the landlocked Atlantic

Salmon spawning season of mid-October to late November. Lake level management in the North Twin impoundment, particularly the 12-foot drawdown, could affect landlocked salmon spawning success by influencing the volume and accessibility of spawning habitat.

Boucher and Warner (2006) suggest that the adult salmon of wild origin in the North Twin impoundment may be more likely to use spawning habitat associated with inlet streams for spawning than other spawning habitats. Landlocked salmon in the North Twin impoundment are primarily wild origin fish (PAD at page 5-93). Therefore, tributaries are likely the dominant spawning areas for landlocked salmon in the impoundment.

Tributary spawning adult salmon must have passage from the open water of the impoundment to the flowing water in the tributary. Movement to spawning areas is triggered by falling water temperature. In the flowing tributaries, female salmon typically build the redds (nests) at the head of a riffle or the tail of a pool where the water is accelerating (Warner and Havey, 1985), because redds require continuous well-oxygenated water (PAD at page 5-92). Based on the PAD, there is limited information on the aquatic habitat in the tributaries, and whether or not access is restricted during drawdown [section 5.9(b)(4)]. Observations of the tributary inlets at full pond and during drawdown, with particular attention to any structural or hydraulic barriers, would provide practical insight into the ability of salmon to access tributary spawning habitat. A comparison of access and habitat quality at full pool versus in a drawdown state could help to identify potential operational, or on-site measures to improve spawning access [section 5.9(b)(5)].

Landlocked salmon are believed to use habitat other than tributaries for spawning, particularly when access to tributary habitat is limited. Other possible spawning areas include shoal areas in the impoundment and the tailrace and riverine areas downstream from the dam. In order to explore salmon movement, behavior, and use of these other potential habitats, as well as tributaries, Maine DIFW requests, and Mr. Spear supports, the Radiotelemetry Study. A radiotelemetry study could track movement of salmon and potentially detect spawning behavior in these areas. However, such a study would have a significantly higher cost than that proposed by GLHA [section 5.9(b)(7)], and it is unclear how a telemetry study would lead to operational or site-specific changes [section 5.9(b)(5)].

Regarding shoal spawning habitat, Maine DIFW states that there is documented evidence that salmon would spawn in impoundments, especially near the mouths of large inlets, in moving water near outlets, and among wind-swept shoals. The PAD shows that there is substrate in the impoundment of the proper size for salmon spawning. Spawning habitat for landlocked salmon consists of areas of unimbedded gravel areas containing substrate ranging from 0.5 to 4 inches in diameter and being well oxygenated (PAD at

page 5-92). GLHA proposes to examine spawning habitat in the tributary inlets and assess conditions for 328 feet up the tributary during site visits for nearly full pool and drawdown conditions. To capture information on shoal habitat, during the drawdown site visit (only) GLHA also could identify for shoal habitat in the area extending 328 feet in the opposite direction, going out from the tributary, into the inlet and toward the open water of the impoundment. In this area, GLHA could identify, photograph, locate with GPS, and assess: (1) shoal spawning habitat apparent at the time of the drawdown site visit; and (2) potential shoal spawning habitat that would exist at higher pool levels that is out of the water and exposed under the drawdown site visit conditions. Because, by definition, these areas would be within 328 feet of the tributary mouth, shallow or exposed, and with hard substrate, they could be waded to or accessed in a small boat. Because salmon that spawn on shoals often do so in tributary inlets, adding this information gathering to GLHA's study would provide some information on the potential for landlocked salmon to spawn on the shoals of the impoundment [section 5.9(b)(6)].

Regarding spawning in the West Branch downstream from North Twin Dam, Maine DIFW states that adult salmon of the North Twin impoundment pass the North Twin Dam going downstream, spawn in the dam tailrace or other areas in the West Branch, and return to the impoundment via the fish ladder. Landlocked salmon are found infrequently downstream from North Twin Dam and are believed to be incidental drop-down individuals. The small number of salmon that inhabit Quakish Lake, Dolby Pond, Millinocket Stream, East Millinocket impoundment, and other riverine reaches of the Penobscot Mills Project area are mostly of hatchery origin. Adult salmon for the radio telemetry work would need to be wild fish caught from the North Twin impoundment. Collecting, tagging, and tracking (with radiotelemetry) an adequate sample size of pre-spawning salmon would be a substantial effort, given the relatively low likelihood that drop-down spawning is a major source of spawning for the impoundment [section 5.9(b)(6)].

In summary, GLHA has proposed a less costly study than the one recommended by Maine DIFW, but it would achieve the common goal of helping to identify operational or onsite protection, mitigation, and enhancement (PM&E) measures. In addition, GLHA's study could also be adapted to make an initial assessment of shoal spawning habitat in the slack water impoundment inlet areas [sections 5.9(b)(7) and 5.9(b)(5)]. The evidence of large-scale dropdown spawning is limited, likely because Maine DIFW stopped stocking the impoundment in favor of natural reproduction in 2018. Finally, Maine DIFW's goals for the Radiotelemetry Study do not appear to be project-related [section 5.9(b)5)].

For all of the above reasons, we do not recommend the Landlocked Salmon Radiotelemetry Study requested by Maine DIFW and supported by Mr. Spear for the North Twin impoundment. Rather, we recommend adopting GLHA's North Twin Impoundment Tributary Access Study. However, we recommend that, in addition to the

study as proposed, a provision be added to assess shoal spawning habitat 328 feet into the impoundment from the line of transition from flowing tributary to slackwater inlet under drawdown conditions. Details of this study provision should be developed in consultation with Maine DIFW.

**Study 18. Upstream American Eel Passage Assessment Study – Presence, Distribution, and Relative Abundance of Juvenile American Eel**

Applicant's Proposed Study

GLHA proposes to conduct an Upstream American Eel Passage Assessment, which would assess the presence, distribution, and relative abundance of juvenile eel in the West Branch. GLHA's goal for the study is to assess whether eel: (1) are found in, or near, the East Millinocket Development's tailwater area; (2) congregate at, or near, the base of the East Millinocket Dam; or (3) attempt to migrate upstream over or around the East Millinocket Dam. GLHA's proposed study would include nighttime visual and boat electrofishing surveys (from June through August), and the use of eDNA[13] techniques to determine if juvenile eel are present at the East Millinocket Development and, if so, their approximate size, abundance, and distribution.[14] GLHA states that, because eel attempting to migrate into the West Branch would first need to pass the East Millinocket Dam, "documenting their abundance and distribution at this location represents a logical first step in assessing the resource issue and potential effects of Project operations."

GLHA also would use eDNA techniques described by Chin *et al.* (2021) to assess the presence and relative abundance of eel in the West Branch. GLHA proposes a pilot eDNA effort to determine whether a positive association between eDNA and the numerical abundance of eels can be demonstrated in the lower Penobscot River (where there is a higher abundance of juvenile eel) and near the East Millinocket Development. To assess the potential association between eDNA concentration and numerical

[13] Environmental DNA (eDNA) is organismal DNA that can be found in the environment. Environmental DNA originates from cellular material shed by organisms (via skin, excrement, etc.) into aquatic or terrestrial environments that can be sampled and monitored using new molecular methods. Such methodology is important for the early detection of invasive species as well as the detection of rare and cryptic species.

[14] The study area for the eDNA pilot study includes select reaches of the West Branch (downstream from the East Millinocket Development), the lower East Branch of the Penobscot River, and mainstem Penobscot River.

abundance, GLHA would use a single methodology[15] to assess the relative abundance of eels at each site at the time of eDNA collection. If a significant positive association between eDNA concentration and relative abundance of eels in the lower Penobscot River is established, GLHA would consult with the resource agencies on the need for additional eDNA monitoring to estimate the spatial distribution and relative abundance of eel within the Penobscot Mills Project area.

Comments on the Study

In its comments on the RSP, FWS states that the general abundance and distribution of eels at the Projects is not in question. FWS notes that the West Branch was historic habitat for eel and the species currently inhabits the projects' impoundments and West Branch river habitat (FERC, 1996; Yoder *et a*l., 2008).

FWS asserts that upstream eel passage siting surveys are needed to determine the optimal locations for locating permanent upstream eel passage facilities at each of the six dams of the projects.[16] In a letter filed October 8, 2021, Maine DMR requests a similar study. The agencies recommend visual surveys for eels staging in pools or attempting to ascend wetted structures downstream, baited eel pots, and using temporary trap/pass devices to find viable sites for permanent eel trap/passage structures.

In the PSP, GLHA responded to FWS's and Maine DMR's request by citing to MBI (2005), which found that eel accounted for about 1 to 2 percent of the total catch in the West Branch. GLHA reports that the Medway Project No. 2666, which is located 0.8 miles downstream from East Millinocket Dam, and is equipped with an upstream eel ladder, passed a total of 88 eel between 2004 and 2015. GLHA concludes that eel likely occurs in low numbers in the Projects' waters. Thus, because little is known about eel distribution in the West Branch, GLHA argues that the surveys requested by the agencies at all six of the Projects' dams would not be productive, and that siting upstream eel passage facilities for the Projects would be unwarranted at this time.

In comments on the RSP, Maine TU states that the presence of eel in the watershed is well established. Maine TU asserts that GLHA is taking a study request that would inform licensing decisions for the projects and replacing it with a study that will not.

---

[15] Depending on permitting, GLHA would use either a fixed distance electrofishing sample (e.g., 30-meter shoreline transect), or a series of eel pots deployed at each site for a fixed duration (e.g., 96-hour)

[16] The six dams at the two projects are the Ripogenus (of the Ripogenus Project) and the North Twin, Millinocket, Dolby, East Millinocket, and Millinocket Lake Storage Dams (of the Penobscot Mills Project).

Discussion and Staff's Recommendations

GLHA, FWS, and Maine DMR agree that an upstream eel passage assessment is warranted to support the relicensing of the Projects. However, GLHA's proposed study plan, and the agencies' recommended study plan, differ in several key areas. They also agree that observations of eel presence, abundance and behavior are needed in the tailrace of East Millinocket Dam. They disagree on: (1) whether or not the scope of the study needs to include the five dams upstream of East Millinocket Dam; (2) the seasonality of sampling; and (3) important details of the sampling methodology.

*Study Scope*

As documented in the PAD, eel are known to occur throughout the Projects' impoundments and flowing reaches of the West Branch. However, existing information from MBI (2005) and the Medway Project eel counts suggest that eel occur in low numbers in the project waters. If that has changed over time, it is likely detectable in the tailrace of East Millinocket Dam, where GLHA and the agencies agree that monitoring is needed. Given the indications that eel abundance is very low in the project waters, surveys at the five upstream dams at this time would be overly costly [section 5.9(b)(7)], given the limited information expected to be gained for the purpose of siting and installing upstream eel ramps [section 5.9(b)(5)]. Therefore, we recommend that GLHA conduct tailrace sampling for eel only at East Millinocket Dam.

*Seasonality of Sampling*

GLHA and the agencies agree that developing a better understanding of eel migration cues and their seasonality is important information to manage eel passage in the West Branch. While GHLA and the agencies may agree on this point, they do not agree on the seasonality for sampling upstream migrating eel. GLHA proposes monitoring for juvenile eels moving upstream in June through August. The agencies recommend a monitoring period of April 1 through November 30, which would extend GLHA's proposed period by 5 months, 2 in the spring and 3 in the fall.

There is a lack of information regarding the seasonality of juvenile eel movement, particularly specific to the West Branch. Studies elsewhere have identified various temperature triggers of upstream movement by juvenile eel including, water temperatures that exceed 59 degrees Fahrenheit (°F) (Hammond and Welsh, 2009), range from 66.2 °F to 82.4 °F (Walsh and Liller, 2013), and are above 50 °F to 53.6 °F (Sullivan *et al.*, 2009). In all three studies, eel movement was associated with high discharge and, in the latter study, with a dark moon phase. These studies, along with other literature, indicate that the exact timing of upstream eel movement in a river system varies considerably.

Based on the studies mentioned above, overall juvenile eel exhibit upstream movement behavior when water temperatures are between 50 °F and 82.4 °F. Combining that temperature range with temperature information provided in the PAD (*see* Table 5.3-10; ranged from a low of 61 °F to a high of 79.5 °F between June and September), the water temperatures downstream from East Millinocket Dam would be suitable for upstream juvenile eel movement from June through September. Based on the data for June and September, water temperature also would likely be conducive to upstream movement of juvenile eel in the months of May and October. There is an overall lack of information on water temperatures in the West Branch for April and November. From December through March water temperatures are likely too cold for significant juvenile eel movement to occur.

The Penobscot River hydropower projects equipped with upstream eel passage that are situated lower in the Penobscot River system operate the ladders from June through August. East Millinocket Dam, however, is situated farther up in the river system, on the West Branch. Because of this geography, the migratory period for eels in the West Branch may extend later than it does in the lower Penobscot River.

Given that: (1) the range of temperatures across which eel could be triggered to migrate upstream occur from June through September with May and October being marginal; (2) the possibility that eel migration would extend later higher in the Penobscot Basin at the West Branch than in the lower portion of the basin; (3) the uncertainty around the triggers and timing of upstream eel migration, including the lack of data specific to the West Branch; and (4) there is a need to understand eel migration and passage at East Millinocket Dam, we recommend that GLHA sample juvenile eel at the East Millinocket Dam from May through October. This sampling season would likely capture the majority of upstream juvenile eel movement in the West Branch, without the expense of requiring GLHA to sample in the months when upstream eel migration is least likely (i.e., from November through April) [section 5.9(b)(7)].

*Sampling Methodology*

With regard to specific methodologies to sample juvenile eel in the West Branch, GLHA proposes night visual surveys, night electrofishing, and an eDNA pilot study. FWS and Maine DMR recommend visual surveys, eel pots, and trap/passage structures. All of the identified approaches are generally accepted methods for sampling juvenile eel. Because of what may be a low number of eels in the West Branch, a combination of survey types would best ensure observing eels.

Typically, visual surveys would occur during daylight hours. While eels may move during the day, they are most likely to move during a freshet at night. Thus, daytime visual surveys may be less efficient than nighttime surveys at observing eel moving upriver [section 5.9(b)(6)]. In its PSP comments, filed on February 18, 2022,

FWS states that using spotlights and binoculars for nighttime eel surveys, are ineffective techniques. However, nighttime visual surveys, of the type proposed by GLHA, have been used at six projects on the Penobscot River (i.e., Milford, Orono, Stillwater, West Enfield, Mattaceunk, and Medway), as well as other rivers in Maine in recent years to identify the need for, and location of, upstream eel passage structures, some of which now pass thousands of juvenile eels annually. Therefore, we recommend GLHA sample juvenile eel at the East Millinocket Dam using visual nighttime surveys, conducted once per week during the upstream migratory season from May 1 through October 31.

FWS and Maine DMR recommend the use of baited eel pots to sample juvenile eel at the projects. In its PSP comments filed February 22, 2022, Maine DMR states that it currently conducts a fishery independent life cycle survey of glass, yellow, and silver eels annually (Atlantic States Marine Fisheries Commission, 2021) using a ramp and pot capture system for glass and yellow eels, and a pot only approach for yellow eels in West Harbor Pond. Baited eel pots are a proven sampling technique for juvenile eel, especially in non-riverine systems. Because West Harbor Pond is a pond situated close to the ocean, the example may not be transferrable to the West Branch, where eel density has been observed to be low. Therefore, we do not recommend baited eel pots for sampling eel at the East Millinocket Development.

Nighttime boat electrofishing is a sampling technique, when coupled with nighttime visual surveys, that is likely to be effective at not only capturing juvenile eels in the East Millinocket tailrace, but also obtaining information on juvenile eel size and the seasonality of eel movement in the West Branch [section 5.9(b)(6)].[17] Therefore, we recommend nighttime boat electrofishing, as proposed by GLHA, to sample eels at the East Millinocket Development. However, electrofishing for one night in June and one night in August, as proposed by GLHA, is insufficient to provide useful information on migration trends [section 5.9(b)(6)]. Instead, we recommend that nighttime boat electrofishing for eel in the East Millinocket tailwaters occur once per month during the potential migratory season, as identified above (May through October) to aid in documenting the presence of eel at the site.

FWS and Maine DMR recommend a trap/passage collection system be employed to sample eel at the Projects partly to obtain information for a site-evaluation for permanent upstream eel passage structures at the Projects. As stated above, we do not recommend eel sampling and siting evaluations for upstream eel passage structures at the

[17] Boat electrofishing was recently used by the Georgia Power Company to sample eel downstream from Lloyd Shoals Dam (part of the Lloyd Shoals Project No. 2336) on the Ocmulgee River in Georgia. The study found that sampling at night using boat electrofishing was more effective at capturing eels than baited eel pots set just downstream from Lloyd Shoals Dam.

five dams upstream of East Millinocket Dam because of the overall low abundance of eel in the West Branch [sections 5.9(b)(6) and 5.9(b)(7)]. However, trap/passage devices can be effective eel collection tools and East Millinocket Dam is likely to need to site permanent eel passage structures. Therefore, we recommend that the Upstream American Eel Passage Assessment Study include a trap/passage device downstream from East Millinocket Dam.

Finally, GLHA proposes a pilot eDNA study to determine if such a technique is feasible to assess the presence and relative distribution of eels in the West Branch. Chin *et al.* (2021) assessed the viability of eDNA as a quantitative tool to assess the presence and relative abundance of eel in the Bronx River, New York, and the authors found a strong positive association between eel eDNA concentration and numerical density. However, the positive relationship they found cannot be generalized to other river systems without further study. The technique would first need to be validated for the Penobscot River Basin.

GLHA's proposed pilot eDNA study would involve collecting eDNA samples from six sites in the Penobscot River Basin (from June to August), including (a) the West Branch downstream from the East Millinocket Development and downstream from the Medway Project, (b) the East Branch of the Penobscot River at a point about 1.5 miles upstream of the confluence, and (c) the mainstem Penobscot River downstream from the Mattaceunk, West Enfield, and Milford Dams. Specific locations would be determined in consultation with the resource agencies. To assess the potential association between eDNA concentration and numerical abundance, GLHA would use a single methodology[18] to collect a standardized sample of eels to assess the relative abundance of eels at each site at the time of eDNA collection. This sampling approach is an acceptable, relatively low-cost approach to determine the presence and relative abundance of eel at the East Millinocket Development [sections 5.9(b)(6) and 5.9(b)(7)]. If a positive association between eDNA concentration and relative abundance of eels in the lower Penobscot River is established, GLHA could consult with the resource agencies on the need for additional eDNA monitoring, or whether a different type of sampling is needed to estimate the spatial distribution and relative abundance of eel elsewhere within the Penobscot Mills Project area. For these reasons, we recommend GLHA's proposed study include the eDNA pilot study for eels.

[18] Depending on permitting, GLHA would use either a fixed distance electrofishing sample (e.g., 30-meter shoreline transect), or a series of eel pots deployed at each site for a fixed duration (e.g., 96-hour).

**Study 19. Desktop Downstream Eel Passage Route and Survival Study**

Applicant's Proposed Study

GLHA proposes to conduct a Desktop Downstream Eel Passage Route and Survival Study. The desktop approach would use: (1) development-specific information; (2) empirical entrainment survival data collected at hydropower projects throughout the United States; and (3) FWS's Turbine Blade Strike Analysis tool (FWS, 2020). The goal of GLHA's study would be to describe the potential effects of the Projects on out-migrating adult eel through: (1) describing the physical and operational characteristics of each of the Projects' developments; (2) calculating approach velocities at the intake for each of the Projects' powerhouses; (3) compiling and summarizing available passage survival data and comparing facility characteristics to those for each of the Projects' powerhouses; and (4) generating an estimate of cumulative survival. GLHA states that this approach represents an appropriate initial step understanding routing possibilities and passage mortality rates for the projects under current operations.

Comments on the Study

In its comments on the RSP, FWS reiterates its recommendation that GLHA conduct the Downstream Eel Passage Assessment requested in its letters filed on October 7, 2021, and February 2, 2022. FWS and Maine DMR[19] request a field evaluation to quantify the effect of downstream passage on adult eels passing through the Projects. The goals of the agencies' study are to determine the effects of the Projects on the outmigration of adult eels in the West Branch. The primary objectives of the requested study are to: (1) quantify the movement rates of eels passing via various routes at the projects; (2) quantify the relative proportion of eels passing each potential emigration route at the Projects during varying operational conditions; and (3) evaluate instantaneous and latent mortality and injury of eels passed via each potential route. The agencies' requested study would consist of two separate efforts that would involve a comprehensive radio- and PIT-tag study to assess routes of passage at the developments and a balloon-tag study to assess mortality/injury at the developments.

Discussion and Staff's Recommendations

American eels inhabit West Branch riverine habitats and have been documented in fish assemblage studies from the 1980s (FERC, 1996) and more recently in 2004 (Yoder *et al*., 2008). As summarized in the PAD, fish assemblage studies conducted as part of the prior relicensing documented that eel are present in the Upper Gorge and the reaches of the West Branch downstream from McKay Station; between North Twin Dam and

[19] In a letter filed October 8, 2021, Maine DMR requests a similar study.

Quakish Lake; the East Millinocket Development tailrace; and Millinocket Stream. The more recent fish community sampling done by Yoder *et al.* (2008) found eels in the reaches of the West Branch downstream from McKay Station (two eels at Big Eddy, one eel at Abol Deadwater, one eel at Debsconeag Falls), in the vicinity of Shad Pond (six eels), and in Millinocket Stream (six eels). Eels that migrate through Project waters could be susceptible to impingement on the Projects' trashracks or entrainment through the Projects' turbines during periods of operation. This could result in delay, injury, or mortality during emigration.

To date, no directed studies of eel entrainment or mortality have been conducted at the Projects. However, eel passage has been studied at the Medway Project, which is located 0.8 mile downstream from East Millinocket Dam. Between 2004 and 2015, 88 eels were observed using the Medway upstream eel passage ramp. Moreover, the Medway passage plan required surveys to determine if an adequate number of migrating adult eels could be trapped at a location upstream of Medway[20] for use in downstream passage effectiveness studies. Catches of adult eel were low, totaling two in 2004, three in 2005, one in 2006, six in 2012, and two in 2013. The result of these efforts documented few adult eels in the West Branch.

While there is a need to address information gaps where it concerns the effects of the Projects on eel survival and passage in the West Branch, it is also important to consider the level of effort involved in studying the effects of the Projects on out-migrating eels. For FWS's and Maine DMR's requested study, about 900 adult, silver-phase, eels would be needed for the route selection component of the study.[21] The agencies did not provide an estimate for the balloon-tagging component of the study, but GLHA provides a preliminary estimate of 375 eels (50 test and 25 control eels per development at each of the five developments). As noted above, efforts to collect active silver-phase eels in the West Branch were not successful and the likelihood of doing so now, within the two study seasons afforded by the ILP regulations, is not realistic [section 5.9(b)(6)]. With regard to using out-of-basin eels as a surrogate, GLHA indicates that out-of-basin eels were used at Medway and at projects on the lower Penobscot River, where sample sizes were limited to 50 eels. Assuming the use of out-

[20] The locations included Millinocket Stream, about 8 miles upstream of its confluence with the West Branch; the West Branch between the Medway Project and the confluence with Millinocket Stream, riverine habitats within Nollesemic and Schoodic Streams, and the lacustrine portion of the Dolby and Millinocket impoundments. Sampling involved a rigid weir, fyke netting, boat electrofishing, trap netting, and eel pots for a 3-night period in mid-August.

[21] The estimate of 900 eels is derived as follows: 150 live test eels per development x five developments = 750 individuals; 75 control eels (25 dead and 50 live) per project x 2 projects = 150 individuals.

of-basin eels at the numbers recommended by the agencies, GLHA estimates that the agencies' requested study could cost $500,000 for a single season; FWS and Maine DMR estimate the cost of their request study to be $100,000 per year for the route selection component and $50-$75,000 for the injury/mortality component.

GLHA's proposed desktop approach would provide: (1) an understanding of the potential downstream passage routes and associated mortality rates for each of the Projects' developments; and (2) a reasonable estimate of entrainment and turbine survival of eels passing through the Projects. This approach would ensure that appropriate data is collected in a more cost-effective manner than requiring the agencies recommended field evaluation ($250,000 to $500,00) to quantify the effects of the Projects on downstream migrating eel in the West Branch [section 5.9(b)(7)]. Therefore, we do not recommend that GLHA be required to conduct FWS's and Maine DMR's requested Downstream Eel Passage Assessment.

**Study 25. Terrestrial, Wildlife, and Botanical Resources Study**

Requested Study

FWS requests a Terrestrial, Wildlife, and Botanical Resources Study. The goals of FWS's requested study include: (1) characterizing and describing the terrestrial, wildlife, and botanical resources that are currently representative of upland habitats within, and adjacent to, the Projects' boundaries; and (2) comparing baseline data collected during the last relicensing proceeding with current conditions of the terrestrial, wildlife, and botanical resources at the Projects. The specific objectives of the field study are to: (1) survey and inventory overall existing upland wildlife habitats; (2) document the occurrence of wildlife sightings during the course of the surveys; (3) survey and inventory vegetation cover classes and land use; (4) survey and evaluate the presence of targeted rare threatened or endangered species or associated habitats, especially of the northern long-eared bat (NLEB) and Canada lynx; (5) survey and inventory the nature and extent of upland invasive and exotic vegetation species; and (6) compare the current species diversity and distribution with the species diversity and distribution collected during the last licensing proceeding.

FWS's requested study would include a literature review to collect information needed to develop vegetation type maps. FWS requests that during field data collection, biologists conduct surveys of bald eagle nests, feeding concentrations, and roosting sites using standard aerial methodology from state and federal wildlife agencies, including photographs and georeferencing. FWS also requests that aerial nest surveys be conducted annually within a half mile of the shoreline of wetlands, rivers, streams, and beaver flowages in April of 2022 and 2023. The study report would include: (1) maps, tables, and summaries of the information above; (2) an assessment of project effects (operations, maintenance activities, potential future recreational amenities, etc.) on

terrestrial habitat, wildlife, and habitat connectivity at the Projects; and (3) recommendations for any necessary vegetation, habitat type, or wildlife protection and/or invasive species control measures, including riparian buffer restoration and protection of key nest and roost trees for bald eagles.

FWS states that without knowing what terrestrial resources currently exist and what wildlife occurs in the project area, or what types of land management and/or maintenance activities GLHA routinely undertakes, it is unable to determine if effects are currently occurring, or if they may occur under any new conditions that could be imposed in a new license.

Comments on the Study

In the RSP, GLHA does not propose to conduct the Terrestrial, Wildlife, and Botanical Resources Study requested by FWS. GLHA states that changes in upland communities over time (i.e., since the previous relicensing) are natural occurrences and/or likely the result of factors unrelated to the Projects' operations. GLHA notes that timber harvesting within the Projects' boundaries is limited to portions of the Wildlife Management Area surrounding the West Branch from Stone Dam to Shad Pond and is performed in accordance with the wildlife protection and enhancement measures defined in the Commission-approved Back Channel Wildlife Management Plan,[22,23] as well as applicable timber harvesting regulations. GLHA also states that it is not proposing modifications to the Projects, at this time, and a Canada lynx study would be premature. Should modifications be required by any new licenses, which could potentially affect Canada lynx (e.g., the development of upland recreational facilities within designated critical habitat), GLHA would consult with FWS at that time to determine the necessary measures to avoid or minimize effects to the species. GLHA also proposes to implement protection measures for NLEB in the event that GLHA proposed, or Commission-required activities could affect potential habitat for the species as an alternative to conducting acoustic surveys.

In lieu of performing invasive plant species surveys at the Projects, GLHA proposes to develop an Invasive Plant Species Management Plan that would be filed with the Final License Application and implemented pursuant to any new licenses. The plan would describe the measures to avoid the introduction or spread of invasive plant species at the Projects during construction or maintenance activities. Similarly, in lieu of

[22] Back Channel Wildlife Management Plan FERC Project No. 2458-Penobscott Mills Article 412. Filed April 21, 1997. Document Accession number: 19970428-0243.

[23] Penobscot Mills (FERC Project No. 2458), Article 412, Supplement to the Back Channel Wildlife Management Plan. Filed January 14, 1998. Document Accession number: 19980120-0258.

performing an aerial bald eagle survey to document bald eagle nests, feeding concentrations, and roosting sites, GLHA proposes to implement protective measures that would be taken during project activities (e.g., tree clearing or construction) that could affect bald eagles over the term of any new licenses.

Reply Comments

In comments on the RSP, FWS reiterates its original request for a Terrestrial, Wildlife, and Botanical Resources Study. In comments on the PSP, FWS notes that the Projects' areas contain habitat suitable for the federally listed NLEB and may contain habitat suitable for the federally threatened Canada lynx and its designated critical habitat. FWS states that, while GLHA maintains that it is not proposing any new construction, changes to current land management practices, or new land management activities as part of this licensing proceeding, the PAD provides incomplete or outdated descriptions of terrestrial resources and no descriptions of the types of land management practices that GLHA currently employs.

Discussion and Staff's Recommendations

FWS's requested Terrestrial, Wildlife, and Botanical Resources Study is very broad and would entail substantial effort and costs to complete extensive surveys and field inventories [section 5.9(b)(7)].[24] On the other hand, GLHA provides little information on its current terrestrial land management activities and any potential effects on terrestrial resources, including federally listed species, in the PAD. Applicants should provide information adequate to describe the current environmental baseline[25] on terrestrial, wildlife, and botanical resources in order for staff to assess the effects of continuing to operate the Projects [section 5.9(b)(4)]. The information is also needed for Commission staff's assessment of project effects on federally listed species. Therefore, as discussed below, we recommend that GLHA conduct a modified version of FWS's requested study.

GLHA proposes other studies at the Projects (e.g., Furbearer, Wood Turtle, Marsh Bird Surveys, and the Riparian and Littoral Habitat Studies) that would provide some wildlife and habitat data that could be included in this study. GLHA's proposed studies, however, do not cover all areas in the project boundaries that are actively managed or

[24] Inventories document and identify all species in a given area.

[25] The Commission's information needs for defining current environmental baseline conditions for environmental analysis in relicense cases was affirmed in American Rivers v. FERC, 187 F.3d 1007, amended and rehearing denied, 201 F.3d 1186 (9th Cir., 1999); Conservation Law Foundation v. FERC, 216 F.3d 41 (D. C. Cir. 2000).

affected by project operation. In order to evaluate the various types of terrestrial habitat present in the project boundaries, particularly habitat available to federally listed species or influenced by invasive species, we recommend that GLHA prepare a map of existing terrestrial cover types in the Projects' boundaries and otherwise affected by the Projects' operations. This map can be compiled from the other relevant studies, other maps, aerial photography, and, as necessary, field verification. To facilitate stakeholder review of the environmental baseline for terrestrial resources, the information from these studies should be consolidated in the Terrestrial, Wildlife, and Botanical Resources Study Report, and be filed with the ISR.

In the RSP, GHLA states that it anticipates development of an Invasive Plant Species Management Plan. However, without information on the occurrences of invasive species at the Projects, it would be difficult for GLHA to develop or, staff to evaluate, the proposal to address issues associated with invasive species. Therefore, we recommend that GLHA conduct terrestrial field surveys for invasive plants in upland areas: (1) within the Projects' boundaries; (2) that are routinely or occasionally managed or affected by project operations or maintenance (e.g., project facilities, recreation facilities, transmission lines, and timber management); and (3) where current information is not available, or would not be collected during other proposed studies.

The PAD states that the Projects' areas contain suitable habitat for NLEB and may contain habitat suitable for Canada lynx and its designated critical habitat. While we do not recommend conducting targeted surveys for these mobile, elusive species, we do recommend a desktop evaluation followed by field verification, if necessary, to determine if their associated habitats are present within the Projects' boundaries, or are affected by the Projects' operations and maintenance activities. With regard to the Canada lynx, GLHA would identify habitat containing the primary constituent elements (PCE) necessary to support this species' life-history functions. For Canada lynx, the PCEs are the essential features of the boreal forest types that provide prey, reproduction and denning habitat, and snow conditions that give lynx a competitive advantage over other hare predators.[26] With regard to the NLEB, GLHA would identify any summer roosting habitat and hibernacula at the Projects. Because the above information would be necessary to complete our analysis of federally listed species [section 5.9(b)(4)], GLHA should provide information about the occurrence of these PCEs for Canada lynx and habitat for NLEB at the Projects that would be affected by operation, maintenance, construction, and/or project-related recreation activities.

The 2,300-acre Wildlife Management Area surrounding the West Branch is subject to a wildlife management plan developed to enhance habitat diversity and

[26] 50 CFR Part 17 Vol. 79, No. 177 September 12, 2014.

increase habitat value for wildlife.[27] GLHA has monitored wildlife management and timber harvesting in this area for the past 20 years, and reported on these activities every 5 years, most recently in 2018.[28] Current information on forest composition, age, understory condition, harvesting schedules for the sections that are actively managed, and wildlife presence from wildlife monitoring could be included in the Terrestrial, Wildlife, and Botanical Resources Study Report. Because current information is available for terrestrial and wildlife resources in areas of the Wildlife Management Area, which are actively managed, the level of effort to assess current resource in these areas should not be extensive [section 5.9(b)(7)].

We do not recommend that GLHA perform aerial bald eagle surveys to document bald eagle nests, feeding concentrations, and roosting sites [section 5.9(b)(5)]. GLHA is not currently proposing any new construction, and forest management is limited to the Wildlife Management Area where GLHA implements wildlife protection and enhancement measures in accordance with the Wildlife Management Plan, as well as applicable timber harvesting regulations. While we are not recommending FWS's request for a survey, we do recommend that any eagle roosting or nesting trees, either previously documented or observed during the surveys, be recorded and georeferenced.

In summary, we recommend a modified version of FWS's requested study. For the first phase of the study, we recommend that GLHA create vegetation habitat maps and calculate the percentage of each vegetation type present in the project area. For the second phase, we recommend that GLHA conduct field surveys to verify vegetative cover types, and document wildlife habitat and occurrence, and invasive plant species in the Projects' areas. The field surveys should be limited to upland areas within the Projects boundaries that are actively managed or affected by the Projects' operations or maintenance activities, and where current information is not available, or would not be collected during other proposed studies. Finally, in order to facilitate the review and analysis of the report by stakeholders, we recommend that the study report include, as generally requested by FWS: (1) maps, tables, and summaries of the information above; (2) an assessment of the Projects effects (operations, maintenance activities, potential future recreational amenities, etc.) on terrestrial habitat, wildlife, and habitat connectivity at the Projects; and (3) identification of potential vegetation, habitat, or wildlife protection and/or invasive species control measures.

[27] Pursuant to Article 412 of the Penobscot Mills Project current license.

[28] GLHA Report on Activities in the Back Wildlife Management Area. Document Accession number: 20180212-5221. Filed February 12, 2018.

**Study 26. Wood Turtle Habitat and Presence Study**

Applicant's Proposed Study

GLHA proposes to conduct a Wood Turtle Habitat and Presence Study (Wood Turtle Study) using a phased approach and in collaboration with Maine DIFW. The goals and objectives of the study are to identify suitable wood turtle habitat in the Projects' areas, determine the presence of wood turtles in the Projects' areas, and, if found, determine whether project operations negatively affect wood turtles. Phase 1 of the study would be performed in 2022 and consists of: (1) a review and evaluation of information provided by Maine DIFW; (2) a desktop analysis of wood turtle habitat; and (3) a review of operations data for the Projects. Phase 1 activities would support the identification of targeted field surveys to be performed during Phase 2 activities. Phase 2 of the study would be performed in 2023, and consists of the targeted field surveys, if deemed necessary based on the results of Phase 1 activities. If performed, the targeted field surveys would be performed in consultation with Maine DIFW.

Comments on Study

In its comments on the RSP, Maine DIFW supports GLHA's proposed phased approach for the wood turtle study. However, given the size and remoteness of the Projects' areas, Maine DIFW recommends that GLHA work with Maine DIFW to ensure that the final field study methodology and objectives are mutually agreed-upon prior to any Phase 1 (and Phase 2, if necessary) field work.

Discussion and Staff's Recommendation

Wood turtles are listed as a Tier 1 Species of Special Concern in Maine and designated as an "at risk species" by FWS currently under consideration for federal listing under the Endangered Species Act. Maine DIFW indicates that wood turtles are present in the West Branch upstream of the Ripogenus Project area, and likely occur in other areas in the vicinity of the Projects based on wood turtle habitat evaluations and surveys in the immediate vicinity of the Projects. Wood turtle nesting and overwintering habitat in downstream riverine reaches may be affected by fluctuating water levels resulting from operation of the Projects.

GLHA's proposed Wood Turtle Study is consistent with Maine DIFW's requested study. GLHA states that if the Phase 2 targeted field surveys are performed, they would be done in consultation with Maine DIFW. We recommend that GLHA also consult with Maine DIFW on the field study methodology prior to proceeding with any proposed Phase 1 reconnaissance surveys, and Phase 2 targeted surveys (if needed) [section 5.9(b)(6)]. However, we do not require that the study methodology and objectives be mutually agreed upon, because the potential exists for mutual agreement to not be

reached, which could result in the loss of study season. Rather, the ISR should document the consultation and explain any disagreements along with GLHA's basis for choosing its study methodology and objectives over Maine DFW's.

**Study 27. Riparian and Littoral Habitat Assessment Study**

Applicant's Proposed Study

GLHA proposes to conduct a Riparian and Littoral Habitat Assessment to: (1) identify and characterize riparian and littoral habitat and quantify the exposed area within the historical fluctuation zones of the Projects' storage impoundments; (2) identify and characterize the existing wetlands within 200 feet of the storage impoundments' shorelines; and (3) document observations of wildlife and invasive aquatic plant species within the Projects' boundaries. The study would use historical operations data to identify the fluctuation zones for the Projects' storage impoundments and quantify the exposed area in the fluctuation zones.

Comments on the Study

In its comments on the RSP, Maine DIFW states that the goal of its requested and related Exposed Aquatic Habitat Assessment is to quantify the total area of exposed aquatic substrate of all waterbodies composing the projects. The requested assessment would determine the amount of exposed substrate, relative to the full pond elevation of each waterbody, under (1) 10-year average annual drawdown for each waterbody; (2) low-water years for each waterbody, using 2021 water levels; and (3) under the maximum allowable drawdown for each waterbody.

Maine DIFW also requested that GLHA conduct a quantitative assessment of exposed substrates in the downstream riverine reaches, including the West Branch downstream from Stone Dam and Millinocket Stream. Maine DIFW acknowledges that GLHA plans to collect the related information as part of other studies (e.g., Historical Operations Data Assessment, Water Quality Study, Instream Flow and Habitat Assessment of the West Branch Downstream of Stone Dam Study, and Wood Turtle Study), but, for ease of review, requests that it be included in the Riparian and Littoral Habitat Assessment.

Discussion and Staff's Recommendation

GLHA's proposed Riparian and Littoral Habitat Assessment Study encompasses most aspects of Maine DIFW's requested study. Three requested components that were not adopted as part of the study are discussed individually below.

With regard to including low water year or maximum allowable drawdown scenarios, these scenarios may result in different conditions in the storage impoundments, with the result that more littoral area of the impoundments is exposed than with the 10-year average annual drawdown scenario [sections 5.9(b)(4) and 5.9(b)(6)] and the level of effort to include them would be minimal [section 5.9(b)(7)]. Therefore, we recommend that they be included in the list of drawdown conditions to be evaluated. Therefore, we recommend that GLHA assess exposed aquatic substrate/habitat for the low water year (e.g., 2021) and maximum allowable drawdown scenarios as part of the Riparian and Littoral Habitat Assessment.

With regard to the riverine habitats in the Projects' areas, GLHA intends to collect information to evaluate exposed substrates and habitat in the riverine reaches as part of other studies. While not part of this study, including the collected information on riverine aquatic habitats from the other studies in the Riparian and Littoral Habitat Assessment Report would be a low-cost way to facilitate review of all of the results pertaining to exposed aquatic habitat that result from operation of the Projects [section 5.9(b)(7)]. Therefore, we recommend that GLHA incorporate the information collected from the other studies, related to exposed aquatic substrates and habitats, in the report for the Riparian and Littoral Habitat Assessment.

Finally, Maine DIFW requests that the exposed habitat assessment encompass all waterbodies composing the projects, including the Millinocket, Dolby, and East Millinocket impoundments. However, these developments are operated essentially as run-of-river facilities, where there are no drawdowns and water level fluctuations remain relatively stable. The amount of exposed aquatic substrate/habitat, due to drop in water levels, is, therefore, negligible in these impoundments and a study of exposed areas is unwarranted [sections 5.9(b)(5) and 5.9(b)(7)]. Therefore, we do not recommend GLHA include the Millinocket, Dolby, and East Millinocket Developments in the Riparian and Littoral Habitat Assessment Study

**Study 29. Furbearer Survey Study**

Applicant's Proposed Study

GLHA proposes to conduct a Furbearer Study to collect baseline data on muskrats and beavers in the Ripogenus Project boundary. The study would enable assessment of potential project-related effects on furbearers. The objectives of the study are to: (1) obtain baseline distribution and habitat presence/absence data and map occurrences of muskrats and beavers within the Ripogenus Project boundary; and (2) describe the

distribution and relative abundance of muskrat houses, muskrat push-ups[29] and beaver lodges[30] in various habitat types within the Ripogenus Project boundary in relation to changing water levels during the seasons. Phase 1 of the study would involve a desktop analysis to identify and describe wetland habitats using the results of the Phase 1 activities of the Marsh Bird Survey (Study 28). In Phase 2, GLHA would document the occurrences and locations (using GPS) of muskrat, beaver, beaver lodges, and muskrat houses and food caches observed while conducting other relicensing studies, as time allows, during field activities from spring to fall 2022.

To supplement the furbearer data collected while conducting other relicensing studies, GLHA proposes to conduct one survey of the Ripogenus impoundment shoreline via boat during the mid- to late fall period (weather permitting) for beaver lodges and muskrat houses and food caches. Perimeter and scanning searches of wetlands and waterbodies or streamside areas would be performed to look for muskrat and beaver signs. A total count of muskrat houses and food caches, muskrat push-ups, and beaver lodges observed would be tallied, and the location of each observation would be recorded.

Comments on the Study

In its comments on the RSP, Maine DIFW notes that GLHA's proposed Furbearer Study at the Ripogenus Project has been modified from Maine DIFW's original study request. Maine DIFW emphasizes that both beavers and muskrats residing in bank dens and backwaters can be difficult to detect, especially muskrats which can live in quite discrete places. Based on the experiences of Maine DIFW's regional wildlife biologists, muskrats frequently reside in bank dens that often require a high level of effort to detect, making detection by observers in a boat unlikely. Maine DIFW stresses that the level of effort necessary for this study would require observers traversing, by foot, backwaters, shallow coves, and other sites where a boat may not be able to travel.

Discussion and Staff's Recommendation

Maine DIFW oversees the management of all furbearers across the state. The 2020-2030 Furbearer Management Plan aims to maintain a healthy, abundant muskrat population in Maine. Muskrats are identified as a Priority 3 Species of Greatest Conservation Need in Maine's Wildlife Action Plan due to their cultural significance to Native American tribes and relatively recent population declines in the Northeast.

[29] Push-ups are areas where muskrats have pushed plant materials up through holes in the ice to create a platform for feeding.

[30] Lodges are well-constructed domed structures comprised of interwoven tree limbs, smaller branches, twigs, and mud.

GLHA's proposed Furbearer Study encompasses the aspects of Maine DIFW's revised study request.[31] However, based on Maine DIFW's comments on the PSP, GLHA's proposed methods for detecting furbearers in the Ripogenus impoundment area may not be sufficient to detect muskrat activity [section 5.9(b)(6)]. Therefore, we recommend that GLHA consult with the Maine DIFW regional wildlife biologists, prior to proceeding with any field surveys in which furbearer data would be collected. For example, if deemed appropriate, intensely surveying areas of likely muskrat or beaver activity, rather than scanning the entire impoundment or wetland margins, may improve the effectiveness of the study. The ISR should document the consultation and explain any disagreements along with GLHA's basis for choosing its study methodology and objectives over Maine DFW's.

**Study 31. Common Loon Management Plan Assessment**

Requested study

Maine DIFW requests a study to evaluate the Common Loon Management Plan at the Ripogenus Project. The objectives of the study are to: (1) assess the use of artificial nest rafts by loons at the Ripogenus impoundment; (2) evaluate loon nesting success under the Common Loon Management Plan; and (3) determine if project operations, particularly during low water years, are affecting loon nesting success and if new strategies need to be incorporated into the plan to minimize negative impacts to loon productivity.

Applicant's Proposed Study

In the RSP, GLHA proposes to conduct a Common Loon Management Plan Assessment. The goal of this assessment would be to summarize existing information collected over the term of the current license related to loons at the Ripogenus impoundment, including specific information on how the existing Loon Management Plan has been implemented. GLHA's proposed assessment would use a desktop approach to summarize existing information. This information would then be used to inform and develop an updated Loon Management Plan anticipated to be implemented at the Ripogenus Project over the term of any new license.

As part of the study, GLHA would compile and summarize the following information into a report: (1) the results of the 1998 and 1999 initial loon surveys performed at the Ripogenus impoundment; (2) the results of the 2000-2010 annual loon nest monitoring done at the Ripogenus impoundment, including, to the extent the

[31] Maine DIFW revised its initial Furbearer Study request in its February 22, 2022, comments on the PSP.

information is available, where the artificial nest rafts were deployed during that period; (3) the annual procedures from 2011 through 2021 used to deploy and maintain the artificial nest rafts; and (4) loon nest locations in relation to bathymetry maps and historic impoundment elevation data.

GHLA argues that the existing 10 years of monitoring data on the Ripogenus impoundment should provide sufficient information to understand nesting habitat and success, as well as evaluate the potential effects of impoundment fluctuations on common loons. GLHA asserts that there would be no significant new information, different from what was collected at the Ripogenus Project from 1998 through 2010, resulting from a new field study as requested by Maine DIFW. Additionally, GLHA states that the existing Ripogenus impoundment information, used in combination with the existing data from studies and monitoring done on other impoundments in Maine, would be sufficient to understand the potential effects of impoundment fluctuations on loons, as well as identify PM&Es at the Projects.

Reply Comments

In comments on the RSP, Ms. Kathleen Houston states that there appears to be little connection between GLHA's proposed methodology for the Common Loon Management Plan Assessment and Maine DIFW's request to determine if project operations are affecting loon nesting success, particularly during low water years, and if new strategies need to be incorporated into the management plan. She questions how summarizing past data, some of which is over 20 years old, would meet Maine DIFW's study request to evaluate loon nesting success and help determine if new strategies need to be incorporated into the Loon Management Plan, particularly under operating conditions since 2010. Ms. Houston asks how evaluating existing information on impoundment elevations would work given that the loon nest monitoring data are from before 2010 and the impoundment data available begins in 2010.

Discussion and Staff's Recommendations

In comments on the PSP, Maine DIFW requests additional information from GLHA on the existing Plan for the Design and Implementation of Artificial Nesting Structures for Common Loons, including, but not limited to: (1) how well the Plan has been adhered to; (2) annual maintenance and deployment of nesting structures; (3) the status of artificial nest rafts during periods of drawdowns; and (4) how frequently artificial nest raft locations have been adjusted during drawdown periods. GLHA's proposed study would include this information and would summarize how the plan has been implemented at the Ripogenus Project since monitoring and reporting ceased in 2010 [section 5.9(b)(6)]. GLHA states that the results of this study would be used to inform an updated plan. GLHA's study approach is consistent with Maine DIFW's

request, and Maine DIFW, in its comments on the RSP, provided no comments on GLHA's proposed study.

Regarding Ms. Houston's comment on GLHA's proposed methodology for analyzing historic data, fluctuating impoundment levels are known to affect loon nesting success. The effects can be assessed regardless of what timeframe is analyzed. GLHA proposes to evaluate the existing loon monitoring data in relation to historic impoundment elevations during the same timeframe by comparing loon nest locations to bathymetry maps and historic impoundment elevation data. Thus, the existing 10 years of loon monitoring data should provide sufficient information to assess the effects of project operation (i.e., impoundment fluctuations) on loon productivity at the Ripogenus Project. GLHA's proposed Historical Operations Data and Assessment would provide information on impoundment fluctuations under more recent and current operations. Additionally, GLHA's proposed Operations Model would provide information on how impoundment levels may change in the future under alterative operating scenarios. GLHA's approach is reasonable, and, therefore, we recommend that GLHA implement the study as proposed.

**Study 32. Recreation Study**

Applicant's Proposed Study

GLHA proposes to conduct a Recreation Study with the goal of collecting information on recreation site conditions and uses at project recreation sites at both the Ripogenus and Penobscot Mills Projects. The specific objectives of the study are to:

- Conduct an inventory of, and map, existing Commission-approved project recreation sites, including locations, facilities and amenities, general condition, ownership, and management responsibility (summer 2022);

- Evaluate recreation use at project recreation sites, including both an assessment of the amount of recreation use that each site receives and the recreation activities that occur at the site for both the summer and winter recreation seasons (May-September 2022, January-February 2023);

- Conduct user surveys at the project recreation sites to assess activities, site conditions, satisfaction with existing facilities, and recommendations regarding the sites and facilities (May 2022-February 2023); and

- Assess the accessibility and useability of select project boat launching facilities provided at the project recreation sites (i.e., Chesuncook Dam Point Boat Launch, Caribou Lake Put-In, Millinocket Lake Boat Launch, Ambajejus Lake Boat Launch, and South Twin Lake Boat Launch) over the range of drawdown

conditions under existing project operations and report on any changes that would be needed at the boat launching facilities to make them useable under the range of expected recreation season water levels (summer/early fall 2022).

Comments on the Study

In comments on the RSP, AW/AMC, the Camp Owners Associations, Maine TU, and Maine Professional Rafting Outfitters (MEPRO) request that the scope of the recreation study be expanded to include all formal and informal recreation sites, as well as those non-project recreation sites located near and adjacent to the Projects. MEPRO also requests that the study consider both public and commercial recreation use. Maine Bureau of Parks and Lands (Maine BPL) recommends that the Umbazooksus West Boat Launch and the Graveyard Point Boat Launch be added to GLHA's proposed Recreation Survey, noting that most campers using the Chesuncook Lake remote campsites launch and/or take-out from these sites.

Maine BPL, AW/AMC, the Camp Owners Associations, and Maine TU request that the study methodology be broadened to also include an online survey; allow for more data to be collected via direct mail surveying; collect input from a stakeholder working group; and conduct interviews with organizational representatives from user groups, representatives of camp owners, and other recreation-related interests, such as outfitters. The Camp Owners Associations request direct mail surveys to camp owners on Ripogenus, Caribou, and Chesuncook Lakes.

The Camp Owners Associations and Maine BPL request that the survey instrument be modified to capture recreation user opinions regarding lake levels at the Ripogenus Project.

The Camp Owners Associations and Maine DIFW provide comments regarding the methodology for the proposed recreation facility inventories, spot counts, and other data that would be collected as part of the Recreation Study. The Camp Owners Associations request that data from site inventories and spot counts be compiled by lake. The Camp Owners Associations also requests that the facility assessments include information about informal recreation sites, including distances from fire pits to the shoreline, and that inventories of boat launches provide an assessment of the launch's surface condition. Maine DIFW requests that GLHA identify the fishing sites used by anglers during spot checks. Maine DIFW also requests that GLHA include an analysis of daily whitewater registrations by weekday for each month from May through September.

Reply Comments

In the RSP, GLHA did not adopt the recommendation of AW/AMC, the Camp Owners Associations, Maine TU, and MEPRO to expand the scope of the study to

include both project and non-project recreation sites. GLHA states that the proposal is overly expansive in both geographic and regulatory scope. Instead, GLHA proposes to conduct a recreation study for the facilities and recreational opportunities over which GLHA has direct management. The full list of sites included in the survey would be developed in consultation with Maine DIFW and Maine BPL.

In its reply comments on the RSP, GLHA clarifies that the proposed study plan includes an online version of the recreation user survey. GLHA intends to deploy survey boxes at each of the project recreation sites which display a QR code that allows access to an online version of the recreation user survey. Further, GLHA plans to work with Maine BPL to install additional survey boxes at the locations indicated by Maine BPL that are primarily used to access the remote campsites on the Ripogenus impoundment.

Discussion and Staff's Recommendations

*Online Survey*

Given the extensive and remote nature of the Projects' areas, conducting surveys at all formal and informal recreation sites, as well as those recreation sites located near and adjacent to the Projects, as requested by AW/AMC, the Camp Owners Associations, Maine TU, and MEPRO, would be costly in terms of breadth and scope [section 5.9(b)(7)]. However, GLHA should use the Recreation Study to develop an understanding of the extent of formal and informal recreation use at the project, as well as how use differs between public and commercial recreational use. Distributing the online survey link to licensing stakeholders via a public website would provide greater survey access and potentially a more robust understanding of recreation use, needs and interest at minimal cost [section 5.9(b)(7)]. Therefore, we recommend modifying the study methodology to require that GLHA incorporate an online survey posted on the relicensing web site for the Projects and distribute a sharable link to the survey via email to all project stakeholders. We do not recommend direct mail surveys to camp owners on Ripogenus, Caribou, and Chesuncook Lakes, as requested by the Camp Owners Associations, rather we expect that the Camp Owners Associations could distribute the email link to their membership [section 5.9(b)(7)].

*Survey Locations*

Adding survey kiosks at Umbazooksus West and Graveyard Point Boat Launches, as requested by Maine BPL, would improve information about users of the remote campsites on Chesuncook Lake [section 5.9(b)(4)]. Further, expanding survey coverage to these areas is consistent with GLHA's proposal to add remote or informal access locations to the study in consultation with Maine DIFW and Maine BPL. Therefore, we recommend that the study include these sites.

*Qualitative Data Collection*

Maine BPL, AW/AMC, the Camp Owners Associations and Maine TU request that GLHA's recreation study include qualitative (interview) component to garner input from organizational representatives. Interviews or focus groups with recreation user groups and commercial outfitters are a standard practice in hydropower relicensing proceedings, and would allow for robust understanding of recreation use, needs and interests in the Projects' areas. When combined with the facility assessment reports and quantitative data collected as part of the user surveys, such qualitative information can be useful in developing a licensing proposal that meet the needs of various users [sections 5.9(b)(5) and 5.9(b)(6)]. Therefore, we recommend that GLHA add provisions for interviews or focus groups with interested individuals representing recreation user groups (e.g., whitewater boaters, anglers), commercial outfitters, and campground owner/operators. Adding this component would allow for information to be obtained on the informal and formal recreation sites at the Projects [section 5.9(b)(5)].

*Survey Questionnaire*

Maine BPL and the Camp Owners Associations both request modifications to the survey instrument to gather data on recreation user satisfaction with lake levels at the Ripogenus impoundment. Adding these questions would not be unduly burdensome and would help GLHA understand tradeoffs between maintaining lake elevations and releasing flows from the Projects [section 5.9(b)(5)]. Therefore, we recommend that GLHA modify survey question 11 to include satisfaction with the lake levels at the Projects, or otherwise address recreation user satisfaction with lake levels as requested by Maine BPL.

In order to partially address the request from Edward Spear to conduct a Creel Survey (*see* Part II – Studies Not Required) and his comments on the RSP, the Recreation Study could also be modified to collect some basic information about the recreational fishery through additional questions on the recreation user surveys. Because adding questions to the recreation survey would require less effort than conducting a separate creel survey [section 5.9(b)(7)], we recommend modifying the survey instrument to include a section of angler-specific questions (e.g., if the user is there to fish, what species are they targeting, how long did they spend fishing/length of trip, what species did they catch, how many fish were kept, approximate size, etc.).

*Facility Inventory and Spot Counts*

Maine DIFW and the Camp Owners Associations propose modifications to the methods used by GLHA for facility inventories, spot counts, and other data collection. The majority of the recommended modifications are minor, and easily accomplishable as GLHA gathers other information during the Recreation Study. We recommend adopting

Maine DIFW's request regarding informal fishing locations and whitewater registration data, as well as the Camp Owners Associations' recommendation regarding boat launch condition assessments. We also recommend that the Recreation Study Report present data by lake, where appropriate, as requested by Camp Owner's Associations. Additionally, we recommend that for any informal recreation sites evaluated, GLHA document the relative relationship between the site's amenities and the shoreline. However, we do not recommend that GLHA add all informal recreation sites to its facility inventory for the reasons specified above.

**Study 33. Whitewater Boating Assessment**

Applicant's Proposed Study

GLHA proposes a Whitewater Boating Assessment that would use existing information and the expert opinion of experienced whitewater boaters to evaluate whitewater boating access, conditions, and opportunities in four of the Projects' reaches: (1) the West Branch downstream from Ripogenus Dam to McKay Station (Upper Gorge); (2) the West Branch downstream from McKay Station to Debsconeag; (3) the West Branch downstream from Stone Dam to Shad Pond; and (4) Millinocket Stream downstream from Millinocket Lake Storage Dam. The methods specified by GLHA are consistent with a Level 1 Whitewater Flow Study as set forth by Whittaker *et al.* (2005).

As part of the study, GLHA would use existing information, internet, and literature reviews to evaluate the physical characteristics of each stream reach, the availability of boating access, and the hydrologic conditions in the stream reach, as well as the relationship between stream flow and recreational boating opportunities for a variety of watercraft. GLHA would then assess whitewater boating opportunities in each of the four study reaches using project operational data, and identify constraints on flow regimes and the resulting availability of recreational boating flows. GLHA would conduct interviews with experienced paddlers using a standardized survey aimed at providing both a quantitative and qualitative summary of whitewater boating conditions in each reach. GLHA also would evaluate demand for whitewater boating within the Projects' areas.

Comments on the Study

AW/AMC, Maine TU, and Benjamin Koehler state that a Level 1 Whitewater Flow Study may not provide a sufficient understanding of the opportunities for whitewater boating in the project reaches, and that GLHA should consider conducting a Level 2 or Level 3 study, depending on the findings of the Level 1 study. AW/AMC recommends a controlled flow release whitewater study of three reaches (Upper Gorge, Millinocket Stream, and West Branch downstream from Stone Dam) following the methods outlined in Whittaker *et al.* (2005). AW/AMC and Benjamin Koehler state that

the goals of the study should be to evaluate flows for paddlers on the four reaches, and not to solely "use existing information and paddler knowledge," as GLHA has proposed. The Camp Owners Associations, MEPRO, and 23 individuals commented on the importance of such a study.

In comments on the survey instrument, question number 9, AW/AMC prefers that, in addition to providing a yes/no response about boatability, the survey instrument include an opportunity for a narrative description of the experience, either categorized as too high, high, medium, low, too low and/or a 1-5 scale of the quality and enjoyment of the experience at the identified flow as was included in question 5. AW/AMC also requests that the survey instrument include a question that asks, "How would you prefer to find out about river flows occurring in this reach in the future?" to provide recommendations for how best to share information about whitewater boating at the Projects with the public.

AW/AMC seeks to collaborate with the licensee to help identify boaters and other paddling related organizations that can assist in identifying potential respondents, and work to increase the sample size of the study. AW/AMC requests clarification as to how surveys would be completed in person as shown on the survey instrument, and requests that GLHA seek local rafting outfitters, visit river access points, and engage directly with paddlers in-person. Additionally, AW/AMC suggests expanding the survey to include an online opportunity for respondents, as well as a kiosk style take-and-drop methodology, which would be able to reach a larger audience. AW/AMC recommends that surveys for the whitewater boating assessment be distributed, as appropriate, alongside the survey used in the Recreation Study.

Finally, AW/AMC requests that all surveys conducted be included in their entirety in the ISR, as scanned or photographed copies, in addition to any summary or aggregate data presented.

Reply Comments

In the RSP, GLHA states that additional evaluation of whitewater opportunities associated with the Projects is unnecessary, and that the AW/AMC request for a controlled flow whitewater study is unjustified. In reply comments, GLHA states that the pneumatic flashboard system at Stone Dam is not capable of consistently providing the precise or sustained flows necessary for conducting a controlled flow study within that reach.

Discussion and Staff's Recommendations

*Controlled Flow Studies*

Controlled flow studies are common for relicensing projects that have bypassed reaches. The Commission has required some licensees to follow methodology as described in Whittaker *et al.* (2005) "Flows and Recreation: A guide to studies for river professionals." Study options within the Whittaker framework include Level 1 (desk-top options), Level 2 (limited reconnaissance options), and Level 3 (intensive studies). The study options are meant to be progressive and consist of the options as phased approaches. The whitewater flow study proposed by GLHA seems to closely follow the Whittaker *et al.* (2005) methodology [section 5.9(b)(6)]. However, a Level 2 or Level 3 study may be deemed necessary as a result of the Level 1 study findings. Therefore, we recommend that GLHA conduct the Level 1 study, as proposed. The need for a Level 2 or Level 3 study would be addressed after the first study season. Following the ISR meeting, stakeholders can propose to modify the study plan, or propose new information gathering or studies [sections 5.15(d) and 5.15(e)].

Further, based on the detailed information provided by GLHA, we recognize that the flashboard system at Stone Dam is not capable of consistently providing the precise or sustained flows necessary for conducting a controlled flow study in the reach below Stone Dam. In the future, if a Level 2 or Level 3 study is warranted, use of the flashboard system for a whitewater flow study can be reevaluated.

*Modifications to the Survey Instrument*

The modifications to the survey instrument requested by AW/AMC, as stated above, are minor in scope [section 5.9(b)(7)] and would improve the quality of the results from the Whitewater Study. Therefore, we recommend a narrative description for question 9, and adding a question related to learning about river flows in the future.

*Expanding Survey Access*

GLHA proposes to interview experienced paddlers to gather quantitative and qualitative information regarding recreational boating use in the study reaches. GLHA proposes to use a standardized survey as part of the interview. The interview-based format proposed by GLHA lends itself best to in-person or tele/video interactions rather than an online survey. However, we do agree that expanding the survey to whitewater boaters familiar with the Projects would likely increase the sample size, improve the quality of the results, and create a more robust set of data [sections 5.9(b)(4) and 5.9(b)(5)]. Therefore, we recommend that GLHA include information about the survey and how to participate, and post the information at each whitewater access point. Interested paddlers could then be added to GLHA's participant list for the survey.

*Data Reporting*

AW/AMC requests that all surveys conducted be included in their entirety in the ISR. We agree that GLHA should make available scanned/photographed copies of any hard-copy surveys, in addition to the summaries provided in the final study report. If GLHA conducts the surveys as oral interviews, either in person or via telephone or video, with permission of the interview subject, GLHA should also retain recordings of the surveys and provide them, upon request, to any interested parties.

**Study 34. Aesthetics Study**

Applicant's Proposed Study

GLHA proposes to conduct an Aesthetics Study to develop baseline documentation of the scenic views, vistas, riverscapes, and other noteworthy features of the Projects from the project recreation sites and other key observation points (KOPs) frequently used by the public. Specifically, five KOPs would be documented at the Ripogenus Project (Abol Bridge, Golden Road Riverside Pull-Off, Golden Road Lakeside Pull-Off, Chesuncook Village, and Ripogenus Dam) and six KOPs would be documented at the Penobscot Mills Project (Route 157 Dolby Pond Crossing, Route 11 Crossing at Green Bridge, Route 11 Pull-Off, Golden Road/Baxter State Road Crossing at Pump Station, Stacyville Road Bridge Crossing, and Millinocket Lake Dam).

As part of the study, GLHA would collect photo and video documentation from the project recreation sites and the KOPs throughout the year. The video and photos would be dated, and flow and operational conditions at the time of the video and photo would be documented. The photos and video, along with the flow and operations data, would be included with the ISR to be filed on April 22, 2023.

Comments on the Study

In its comments on the RSP, Maine BPL requests that GLHA include an assessment of the visual impacts of drawdowns of the Ripogenus impoundment (specifically Chesuncook Lake) from a boater's perspective, rather than taking photos or video from the shoreline only.

AW/AMC states that they are concerned that the proposed study would rely exclusively on photo and video documentation and would not solicit or incorporate feedback from the public about how project operations affect visual resources. AW/AMC suggest that GLHA could use intercept or online surveys to collect data on visual resource preferences. AW/AMC and the Camp Owners Associations recommend that GLHA form an aesthetics study working group to further refine the KOPs, survey

instruments, and data collection methods. AW/AMC recommends that GLHA specify that the aesthetic evaluation would be conducted by the working group and other stakeholders on-site, rather than solely relying on a review of photographic documentation of its facilities and operations.

Discussion and Staff's Recommendations

GLHA's proposed study describes the methods for collecting images and video of existing visual resources from shoreline locations, including recreation sites and KOPs. It does not provide methods for collecting data by boat that would be representative of views of the shoreline from the water. However, Ripogenus Project operation has the potential to affect the quality of boaters' experiences by modifying visual resources. Therefore, we recommend that, in addition to the project recreation sites and identified KOPs, GLHA collect representative photos and/or video from a boater's perspective on Chesuncook Lake [section 5.9(b)(4)].

While GLHA provides a description of methods for data collection, the study plan contains no discussion of how the data would be evaluated. AW/AMC and the Camp Owners Associations recommend using a working group to develop methods for evaluating the quality of visual resources under different flows and operating characteristics, and suggest using online or in-person surveys to determine public preferences for visual resources at the Projects. While these recommendations suggest an interactive approach to evaluate the quality of visual resources, similar to GLHA, they don't provide a clear method of how to assess or interpret the findings of such surveys. Therefore, we recommend that GLHA adopt a proven methodology for visual resources assessment, such as the Bureau of Land Management's Visual Resource Management (VRM) methodology [section 5.9(b)(6)].[32] This methodology identifies visual values and develops classifications to describe the level of change from the existing conditions, allowing for informed future management decisions. VRM also recommends using an interdisciplinary team for visual resource evaluations, rather than public surveys. If VRM is used, we recommend that the evaluation team include representatives from GLHA and stakeholder groups. We recommend this approach over public surveys to collect visual preference data. The VRM analysis, combined with data collected in the Recreation Study's user survey, would be sufficient to understand preferences regarding visual resources at the Projects.

For the reasons discussed above, we recommend adopting GLHA's proposed Aesthetics Study, with the addition of data collection points on Chesuncook Lake. We

[32] This methodology is publicly available through the BLM and can be used to identify and evaluate visual values and changes in visual quality resulting from a proposal. Further information is available at https://www.blm.gov/programs/recreation/recreation-programs/visual-resource-management.

also recommend that GLHA's proposed study be modified to require use of VRM or an equivalent visual resource assessment tool. The Aesthetics Study should be conducted in consultation with Maine BPL, AW/ATC, the Camp Owners Associations, and other interested stakeholders.

**Study 37. Socioeconomic Study/Environmental Justice Analysis**

Requested Study

The Penobscot Indian Nation requests that GLHA form a Socioeconomic Working Group and conduct a Socioeconomics Study to assess existing socioeconomic conditions in the Projects' areas. The Penobscot Indian Nation's study would include an evaluation of existing conditions, including population, housing, economic development, public services, local energy production, and State statutes related to energy production, fiscal conditions, and infrastructure. The requested study would also describe current socioeconomic trends in the Projects' vicinity, and how measures implemented at the Projects may affect these trends. The Penobscot Indian Nation requests that the study be developed with extensive input from stakeholders to determine priorities for the use of resources with the potential to be affected by the project. To support this request, the Penobscot Indian Nation points to changes in the local economy as a result of the operation of the Projects and the associated paper mills, as well as the effects of the Projects on cultural, outdoor, and other economic opportunities in the region. The Atlantic Salmon Federation, AW/AMC, the Camp Owners Associations, Maine TU, Maine Professional Rafting Outfitters, and Dr. Sharon Klein filed comments supporting the Penobscot Indian Nation's requested study.

In addition to the requested socioeconomic study, the Penobscot Indian Nation requests additional information on how the project would, or would not, disproportionately affect minority and low-income people living in the region, and how factors relating to environmental justice would be considered in staff's analysis of the Projects' effects.

Comments on the Study

In response to the Penobscot Indian Nation's request, GLHA states that many of the areas of interest to the Penobscot Indian Nation would be addressed by other studies. GLHA further states that the Penobscot Indian Nation did not propose a specific methodology, and instead requests the development of a working group to identify parameters to be evaluated using existing models for socioeconomic estimation. GLHA also states that, as described in the Penobscot Indian Nation's request, there is no nexus between the Projects' continued operation and maintenance and socioeconomic issues and concerns within the project vicinity. Lastly, GLHA states that information from a socioeconomic study of non-power benefits of the river would not inform specific license

conditions; rather, GLHA points to resource-specific studies that have the potential to inform license conditions more directly.

Discussion and Staff's Recommendations

Section 5.18(b)(5)(ii) of the Commission's regulations requires that applicants for new licenses provide a description of the affected environment and an analysis of the project's proposal on socioeconomic resources in the license application. Specifically, Section 5.6(d)(3)(xi) of the Commission's regulations requires that applicants provide a general description of socioeconomic conditions in the vicinity of the project including general land use patterns (e.g., urban, agricultural, forested), population patterns, and sources of employment in the project vicinity. The information contained within the license application must reflect existing conditions, and, where relevant, should contain information about changes in conditions over the term of the last license issuance. Section 5.18(b)(5)(ii)(B) also requires that the final license application contain an analysis of how the project's proposal would affect these socioeconomic conditions.

As part of staff's environmental analysis, we intend to evaluate, to the extent feasible, the effects of relicensing the project, on socioeconomic resources. Where the effects of GLHA's proposal can be reasonably quantified (lost generation, for example), we will do so. For non-power resources, as has been our practice, our analysis will be qualitative in nature. We do not typically require studies that attempt to quantify the economic value of environmental, recreation, or cultural resources. Rather, in addition to the existing information contained in the PAD, the effects on or benefits to these resources should be reasonably identified in other studies approved as part of this SPD. The results of these studies could be used to develop PM&E measures, as necessary.

Although we do not recommend that GLHA pursue a broad socioeconomic study, as requested by the Penobscot Indian Nation, we do recommend that GLHA perform a more narrowly defined study of the Projects' potential to impact minority and low-income populations in the project vicinity. Executive Order 14008, *Tackling the Climate Crisis at Home and Abroad,*[33] and Executive Order 12898, *Federal Actions to Address Environmental Justice in Minority Populations and Low-Income Populations*,[34] as amended, require federal agencies to consider if effects on human health or the environment would be disproportionately high and adverse for environmental justice communities in the surrounding area resulting from the programs, policies, or activities of federal agencies.

[33] 86 Fed. Reg. 7,619-7,633 (January 27, 2021).

[34] 59 Fed Reg. 7,629-7,633 (February 16, 1994).

Based on staff's preliminary analysis of 2019 American Community Survey 5-year estimates, there are a number of U.S. Census block groups within 1 mile of the Projects' boundaries that exceed thresholds for minority or low-income populations, and should be considered environmental justice communities for the purpose of the Commission's NEPA analysis. Therefore, to provide additional information relevant to the analysis of the Projects' effects on environmental justice communities, we recommend that GLHA conduct an Environmental Justice Study using the methodology outlined in Appendix D. To date, this methodology has been applied in a number of Commission proceedings and is consistent with recommendations from the Environmental Protection Agency (2016). We expect that the results of the recommended analysis, combined with the socioeconomic information required to be contained within the final license application, will be sufficient to address existing information gaps regarding the effect of continuing to operate the Projects on socioeconomics and environmental justice communities. We anticipate that the study can be conducted in a single season, in consultation with the Penobscot Indian Nation and other relicensing stakeholders, with an estimated cost of $25,000. Results of the study should be included with the ISR to be filed on April 22, 2023.

## II. Studies Not Required

### Study 3. Indicators of Hydrologic Alteration Model

Requested Study

NMFS requests that GLHA conduct a study to evaluate the effects of operating the Projects on the hydrology of the West Branch and mainstream Penobscot River using the Indicators of Hydrologic Alteration (IHA) and Range of Variability Approach (RVA) methods, as described by Meridian (2004) and Richter *et al.* (1996, 1997). The goal of the study would be to evaluate the effects of the Projects on the hydrology in the West Branch, as well as the mainstem Penobscot River downstream to the Penobscot Bay estuary. The specific objective of the study is to characterize metrics of hydrologic alteration due to Project operational effects, then to identify target flows and impoundment levels using the RVA method. NMFS indicates that it is not the intent to consider "pre-project" conditions in the analysis for the relicensing; but, rather to inform future license conditions that are protective of aquatic resources in the West Branch and areas downstream from the Projects that are affected by the Projects' operations by contrasting what current conditions are with conditions that are protective of aquatic resources.

NMFS requested study would evaluate:

- seasonal effects of the Projects' operations on flows in the West Branch to the Penobscot Bay estuary that may affect Atlantic salmon and their critical habitat;
- seasonal effects of the Projects' operations on flows in the West Branch and mainstream Penobscot River to the Penobscot Bay estuary that may affect survival of sea-run fish communities, including alosines,[35] American eel, and sea lamprey;
- consistency of the Projects' operations to protect state and federal water quality standards;
- effects of the Projects on instream habitat in project-affected stream reaches, including minimum flow, peak flows, and ramping rates; and
- effects of the Projects on access to tributaries downstream from the Projects.

[35] The term alosines is a collective term for American shad, blueback herring, and alewife.

NMFS contends that the Projects' operations and maintenance activities directly and indirectly affect hydrology throughout the West Branch and the mainstem Penobscot River. In addition, NMFS states that downstream from the East Millinocket Development, various additional flows influence the magnitude and seasonality of flow in the mainstem Penobscot River, including flows from the East Branch of the Penobscot River, for which GLHA has no control. NMFS states that the results of this study would be used, in conjunction with the results of other resource-specific studies, to evaluate potential effects of the Projects and to inform licensing decisions regarding those effects.

Comments on Study

In the RSP, GLHA does not propose to conduct NMFS's requested study. GLHA states that the IHA Model was developed as a statistical tool to compare existing hydrologic conditions in a stream or river reach to unregulated hydrologic conditions. GLHA states that conducting such a comparison for the West Branch or any other reach of a highly regulated river system, such as the Penobscot River is unnecessary, asserting that "the IHA model will not provide any useful information regarding the effects of the Projects' operations on Atlantic salmon or other sea-run fish species. It will only point out how hydrologic conditions in the river basin differ from conditions that may have existed prior to construction of the Projects."

GLHA also comments that the study is not necessary because existing information is sufficient to answer the questions posed by NMFS. GLHA states that understanding how current flows in the West Branch and mainstream Penobscot River is a question that has been previously studied and evaluated, most recently during the Mattaceunk Project relicensing. Thus, GLHA argues that a study to evaluate the effects of the current flow regime from the Projects on the mainstream Penobscot River, which was determined to benefit Atlantic salmon and their critical habitat, as well as other sea-run species, is unnecessary. GLHA believes that the proposed water quality studies, instream flow studies, and the historical operations and modeling studies will be sufficient to inform Commission staff's environmental analysis and licensing decisions for the Projects.

Reply Comments

In its March 31, 2022 reply comments on the RSP, NMFS states that its original comments on the PSP stand. In its April 27, 2022 supplemental reply comments on the RSP, NMFS elaborates on its request for an IHA assessment. NMFS analyzed the 10 years of operations data that GLHA provided in the RSP, and provides an analysis of flow profiles obtained from the North Branch of the Penobscot River[36] flow gage

[36] The North Branch of the Penobscot River is a major, unregulated tributary of the West Branch that represents a natural flow regime. A run-of-river hydroelectric

compared to the flow profiles through the Projects. NMFS observes that the analysis shows very consistent, but different, flow profiles through the unregulated portions of the West Branch compared to the regulated portions of the West Branch. NMFS also provides a comparison of the Projects' operations with required minimum flow for both recreation and aquatic resources, and finds that more than the required minimum flows were released for significant periods during 2019, 2020, and 2021. Based on the analysis of the flow data, NMFS reiterates its request that the Commission require GLHA to conduct an IHA assessment to evaluate the effects of the Projects on the hydrology in the West Branch and mainstem Penobscot River downstream to the estuary.

Kathleen Houston, in her comments on the RSP, observes that the 10-years of operations data for the Projects supports the notion that GLHA releases more flow than is required by the current licenses. Ms. Houston asserts that these releases have negative effects on Ripogenus impoundments levels, as well as aquatic and recreational resources in the impoundment and river. For these reasons, Ms. Houston states that NMFS's requested study is necessary to evaluate the effect of current operations.

Discussion and Staff's Recommendation

As described in the PAD, filed on June 11, 2021, the Projects' current operations directly affect the aquatic habitat in the West Branch and mainstem Penobscot River. For example, storage of water in the Ripogenus, North Twin, and Millinocket Lake Storage impoundments affects the timing and magnitude of spring flows downstream of the impoundments. Migratory fish rely on hydrologic cues afforded by spring flows to aid them in their migration. There currently is little information in the record on the effects of the Projects' existing operations on aquatic resources in the West Branch and mainstem Penobscot River.

NMFS's requested study is one approach to address the potential effects described above. An IHA model provides a hydrologic analysis technique that considers the overall hydrological requirements of the system (Meridian, 2004). Meridian (2004) identifies a theoretical hydrologic regime that could improve biotic composition, structure, and function of the river system, and the RVA method is a tool that is used to identify flow targets based on the results of IHA analysis and the goals for meeting resource objectives.[37] There are 32 statistical metrics in the IHA model that focus on descriptors

project in the West Branch would have a flow regime similar to what is observed at the North Branch flow gage.

[37] The RVA method is a river reach- or river basin-scale approach that establishes target flows for river management according to the natural (unimpaired) hydrologic regime in a river system (Meridian, 2004). These management targets could then be used

of the streamflow regime that are considered to be important to the biological and physical integrity of a river. The 32 metrics derived in the IHA analysis can be clustered into five groups, which can then be used to assess potential environmental effects. According to Richter *et al.* (1996, 1997, and 1998), the five groups of the IHA metrics include: (1) magnitude of monthly water conditions; (2) magnitude and duration of annual extreme water conditions; (3) timing of annual extreme water conditions; (4) frequency and duration of high and low pulses; and (5) rate and frequency of change in water conditions. The RVA analysis begins with a comprehensive characterization of ecologically relevant attributes of a flow regime using the IHA model, then uses the results to develop a flow regime that would maintain or improve the aquatic community of the subject river system (Meridian, 2004).

Regarding the requirement for other projects to use an IHA/RVA analysis to develop a relicensing record, the decision for Commission staff to recommend an IHA/RVA analysis is made on a case specific basis.

Regarding this specific instance, in order to assess the effects of flow regulation conditions on project-affected river reaches, flow characteristics would need to be computed and comparison tables prepared for the inflow and outflow. However, there are no streamflow gages on the West Branch, including in the area of the Projects. Rather, generation records would be used to estimate flow through the system, and NMFS states that GLHA would need to conduct index testing to verify the accuracy of the flow estimates at the Projects. The IHA software can be run for a single hydrograph, without an unimpaired flow comparison. However, without such a comparison the RVA method cannot be applied. The alternative to using the RVA method is to compare the IHA values for existing hydrologic conditions to available information on the ecological effects of the flows observed. Using this approach, GLHA would use the existing operations information, along with GLHA's proposed Water Quality Study, Historical Operations Data Assessment, and Operations Model, to assess the Projects' effects on the hydrology in the West Branch and mainstem Penobscot River [section 5.9(b)(4)]. Therefore, we do not recommend that GLHA be required to conduct NMFS's IHA Modeling Study, but instead use information from the proposed Water Quality Study, Historical Operations Data Assessment, and Operations Model to assess how the Projects affect flow in the West Branch and mainstem Penobscot River.

---

to help develop and implement river management strategies such as reservoir operations or stream diversions.

**Study 4. Ramping Rate Study**

Requested Study

Edward Spear requests a ramping study to determine the appropriate rate of flow changes below McKay Station. Mr. Spear notes that fish and aquatic communities can be vulnerable to rapid changes in flow which can disrupt the movement and feeding of, and strand, fish and aquatic insects. The objective of the requested study is to determine the appropriate rate at which flows from McKay Station can be ramped up or down to minimize the effects of project operations on aquatic resources. The study requested by Mr. Spear would result in an independent, peer-reviewed water management plan that includes an up- and down-ramping prescription that is protective of sensitive aquatic insects and salmonids.

Comments on Study

In the RSP, GLHA does not propose to conduct the requested study. GLHA states that information collected and reported from other studies, such as the Historical Operations Data Assessment, will provide information on how the Ripogenus Project is operated, including flows from McKay Station. Additionally, GHLA states that field work conducted below McKay Station, such as the Wood Turtle Study, will provide additional information on flows as they relate to aquatic organisms.

Reply Comments

In his reply comments on the RSP, Mr. Spear indicates that 10 years of hourly flow and elevation records are of no use when considering (rapid) flow change over a short timeframe. Mr. Spear states that the issue is not an evaluation of past practices, but rather of future rates of flow change that should, in his view, be limited to protect aquatic organisms under any new license. Mr. Spear states that it is difficult to imagine the Wood Turtle Study, even one preformed with scuba gear, as contributing useful ramping information.

Discussion and Staff's Recommendations

As discussed in our recommendations regarding Study 5, the Fish Stranding Study, rapid changes in flow and decreases in water surface elevations can increase the risk of fish and invertebrate stranding that can be stressful and/or lethal for aquatic organisms. As indicated by GLHA, the proposed Historical Operations Data Assessment, would provide information on how the Ripogenus Project is operated, including flows provided by McKay Station. However, it is unclear how this study would determine whether the current rate of downstream flow changes adversely affects aquatic resources or how it would determine the rate at which flows from McKay Station can be ramped up

or down to minimize the effects of project operations on aquatic resources. While the Wood Turtle Study would help to evaluate the effects of downstream flows on the wood turtle, it is unclear how that study would support evaluating whether downstream flow changes adversely affect aquatic resources such as fish and aquatic invertebrates, which may be stranded in isolated pools of water or how it would determine the rate at which flows from McKay Station can be up ramped or down to minimize the effects of project operations on aquatic resources.

In our review of the Fish Stranding Study, we recommend evaluating the range of flows under which generator trips at the McKay Station are likely to occur as a way of helping to identify specific conditions that lead to low flow excursions. Accompanying field surveys, required in the Fish Stranding Study, would evaluate fish and invertebrate stranding potential and document stranding that occurs during low flow excursions. Collectively, these results would help determine whether ramping requirements, as requested by Mr. Spear, are warranted [section 5.9(b)(7)]. Further, the results of the Fish Stranding Study would inform the development of license requirements surrounding emergency minimum flows and the rate at which downstream flows are increased or decreased if necessary [section 5.9(b)(5)].

Because the information sought by Mr. Spear would be collected as part of the recommended Fish Stranding Study, we do not recommend GLHA also conduct Mr. Spear's requested Ramping Rate Study.

**Study 11. River Temperature in West Branch and Mainstem Penobscot River Study**

Requested Study

NMFS requests that GLHA conduct a study to evaluate project effects on temperature in the West Branch and mainstream Penobscot River (River Temperature Study). Citing Mantua *et al*. (2010), NMFS asserts that the combined effect of a warming climate, along with altered stream flows due to hydropower dam operations, can negatively affect the reproductive success of salmonids. NMFS states that, currently, there is no information on the effects of operating the Projects on ambient river temperatures in the West Branch or mainstem Penobscot River. The study requested by NMFS would involve: (1) modeling the seasonal effects of the Projects' impoundments and flow modifications on the West Branch and mainstem Penobscot River water temperatures and comparing those temperatures to those that would occur if the West Branch were unmodified by dams; (2) collecting water temperature profiles in the Ripogenus and North Twin impoundments; and (3) developing an alternatives analysis to provide information on the efficacy of potential measures to address any project effects on water temperature.

Comments on Study

In the RSP, GLHA does not propose to conduct NMFS's requested study. GLHA states that, in lieu of modeling river temperatures, it is proposing a comprehensive water quality monitoring study that would include collecting: (1) water temperature profile data in all basins of the Ripogenus and North Twin impoundments, as well as the Millinocket Lake Storage impoundment; and (2) continuous water temperature data in the riverine reaches affected by project operations, including the West Branch downstream from the East Millinocket Dam. In addition, GLHA states that its proposed Operations Model can be used to simulate different operational alternatives based on various water years and operating scenarios.

Reply Comments

In its reply comments on the RSP, NMFS reiterates its original study request.

Discussion and Staff's Recommendation

The West Branch drains 24 percent of the Penobscot River basin (NMFS, 2009) and about 57 percent of the West Branch is impounded by dams (Corps, 1990). In the PAD, GLHA states that the Projects are operated to "dampen the variability and occasional extremes of seasonal precipitation." This mode of operation may modify water temperatures that could affect survival of sea-run fish in the mainstream Penobscot River, including the federally endangered Atlantic salmon and its critical habitat. As NMFS has indicated, there is currently no water temperature information for the Projects on which to base an analysis of any effects, or to inform license conditions to address such effects. However, NMFS's requested River Temperature Study is not necessary to inform future license conditions for the Projects [section 5.9(b)(5)]. GLHA is proposing to collect water temperature profile data in the Projects' impoundments, as well as continuous water temperature data in the riverine reaches affected by the Projects. This information, along with information from GLHA's proposed Historic Operations Data Assessment, can be used to evaluate the effects of project operations on water temperature in the West Branch and mainstream Penobscot River.[38] Moreover, GLHA's

[38] Flow from the East Millinocket Dam enters the Medway Project's impoundment before entering the mainstream Penobscot River at its confluence with the East Branch of the Penobscot River. The Medway Project has a small (120-acre) impoundment and the station is a run-of-river facility. Given the dam (with flashboards) is less than 21 feet in height and its retention time is small, the Medway Project likely has little, if any, effect on water temperatures in the West Branch.

proposed Operations Model can be used to simulate alternatives for future project operations that consider aquatic habitat and species needs in the river.

Regarding NMFS's request for a comparative analysis to water temperatures if the West Branch were unimpaired by dams, the Commission defines baseline during a relicensing process as the conditions that exist at the time of relicensing. Thus, studies that seek to examine a theoretical, non-project condition is not relevant to a proposed licensing action. Moreover, conducting such an analysis would essentially describe pre-project conditions, rather than provide for an assessment of the conditions that would exist with potential environmental enhancement measures. For these reasons, the requested comparative analysis would not inform the development of license conditions [section 5.9(b)(5)].

Because the potential effects on water temperature can be conducted using the information to be provided by GLHA's proposed Water Quality Study, Historic Operations Data Assessment, and Operations Model, we do not recommend that GLHA also conduct NMFS's River Temperature in the West Branch and Mainstem Penobscot River Study.

**Study 12. Future Flow and Water Temperature Scenarios/Climate Change Study**

Requested Study

NMFS requests that GLHA conduct a study to evaluate future flow and water temperature conditions in the West Branch and mainstem Penobscot River. The goal of this study is to evaluate how operation of the Projects would affect future stream flow and temperature in the rivers. NMFS's requested study would involve: (1) identifying a minimum of four future climate scenarios; (2) modeling the seasonal anticipated future effects of impoundment and flow modifications on river temperatures and flow in the West Branch and mainstem Penobscot River compared to an unimpaired river for each scenario identified in item 1; (3) identifying a range of physical and operational modifications necessary to ameliorate the effects of each climate scenario modeled; and (4) assessing how impoundment operations, access to tributaries for fish and other aquatic life, and water temperature and DO concentration in the Projects' areas would be affected by projected future flows in the river. NMFS's requested study would involve analyzing downscaled temperature and precipitation data to assess future risks,[39] which NMFS states can provide a range of likely future scenarios.

[39] Downscaling methods require a variety of input parameters and the models are highly sensitive to input data sources (Walton *et al.*, 2020). Because streamflow gaging records are not available for the West Branch, it is unclear how accurate the methods could be in predicting future operations for the Projects.

NMFS asserts that there currently is no information on how the Projects' operations would affect future stream flows and water temperature in the West Branch and mainstem Penobscot River. Moreover, NMFS states that the combined effect of a warming climate, along with altered stream flows, could directly affect the survival of Atlantic salmon and other sea-run fish in the Penobscot River Basin. NMFS suggests that the results of this study could be used to evaluate the effects of the Projects on Atlantic salmon and their critical habitat and to define the necessity and scope of potential PM&E measures.

Comments on Study

In the RSP, GLHA does not propose to conduct NMFS's requested study. GLHA states that it recognizes the importance of climate change, but indicates that the potential hydrologic changes that may occur over the course of 30- to 50-year licenses are far too unpredictable to allow for quantitative evaluation as requested. GLHA argues that it is not clear how the information obtained from the requested study would inform license conditions for the Projects. GLHA notes that weather patterns in Maine are highly variable and that operational flexibility will be vital to accommodate future annual and seasonal hydrologic variability.

Reply Comments

In its reply comments on the RSP, NMFS reiterates its original study request.

Discussion and Staff's Recommendation

Flow and temperature conditions may change over the proposed license term due to climate change. Information indicates that the climate in Maine is warming and will continue to warm, and as a consequence, precipitation type, rates, and duration will continue to change (Allan *et al.*, 2021; Fernandez *et al.*, 2020). For example, the University of Maine's Climate Change Institute reports that Northern Maine's average annual temperature has increased by 3.1 degrees Fahrenheit (°F) since 1895, and about 1.4 °F over the last 30 years (Fernandez *et al.*, 2020). Allan *et al.* (2021) project that the climate of the Northeast United States will trend towards warmer and wetter weather.

Along with a warming climate, Maine has seen changes in precipitation patterns. Fernandez *et al.* (2020) report that the average annual precipitation has increased by 5.8 inches (or 15 percent) since 1895, and the average annual snowfall for Maine has decreased by 2.3 inches (or 20 percent) over the same time period. Most of the increases in precipitation are associated with increased intensity and duration of fall storm events, and despite the increases in annual precipitation, drought events in Maine have become more severe both in duration and magnitude.

Despite the trend toward warmer and wetter conditions in Maine, there remains uncertainty in the reliability of predicting how precipitation, snowmelt, evapo-transpiration, ice out, and annual runoff patterns may change. Downscaling techniques, such as those NMFS recommends, add a level of process-based uncertainty into the models that are passed to the downscaled projections, creating even greater uncertainty. Such uncertainty would preclude the identification and development of specific alternative operational scenarios that could be considered to mitigate any potential future climate change effects [section 5.9(b)(6)]. Moreover, current guidance from the Council on Environmental Quality (2016) states that "in accordance with NEPA's rule of reason and standards for obtaining information regarding reasonably foreseeable effects on the human environment, agencies need not undertake new research or analysis of potential climate change impacts in the proposed action area but may instead summarize and incorporate by reference the relevant scientific literature."

Finally, even under a best-case scenario where flow and temperature model results could accurately predict future variability at a project scale, it is not clear how that information would better inform license conditions for the Projects than what GLHA proposes [section 5.9(b)(5)]. GLHA proposes to collect water temperature data from the Projects' impoundments and downstream reaches affected by the Projects' operations, including downstream of the East Millinocket Development, as well as summarize historic operations data for the Projects. In addition, GLHA proposes to develop an Operations Model that can be used to simulate operational alternatives based on various water year classifications (i.e., wet, normal, dry). This information should be sufficient to evaluate the Projects' effects on aquatic resources in the West Branch and mainstem Penobscot River, including Atlantic salmon and their habitat, under a wide range of flow conditions including those under droughts to those under wet periods.

For the reasons explained above, we do not recommend GLHA conduct NMFS's requested Future Flow and Water Temperature Scenarios/Climate Change Study.

**Study 16. Ripogenus Impoundment Zooplankton Study**

Requested Study

Edward Spear requests that GLHA conduct a study to evaluate the zooplankton population in the Ripogenus impoundment and its relationship to larval and juvenile rainbow smelt. Mr. Spear references the poor quality of the impoundment's zooplankton community, smelt population (a major food source for the salmon),[40] and the current

[40] Smelt are dependent on zooplankton for their food source, and favor "large" bodied prey (e.g., midges), and plankton communities can change with season and lake basin.

relatively small landlocked salmon size in the Ripogenus impoundment as the bases for his requested study. The goal of the requested study would be to determine whether or not the depressed populations of rainbow smelt and reported small size of salmon are a function of zooplankton abundance that is allegedly affected by operation of the Ripogenus Project. Mr. Spear states that the exact mechanism that leads to the depressed zooplankton and smelt populations are unknown, but he asserts that they are directly related to lake level management in the Ripogenus impoundment. Mr. Spear states that there are no existing data on the growth and abundance of smelt populations, or the zooplankton communities, in the Ripogenus impoundment to fill this data gap. Mr. Spear provides no details regarding the methodology for conducting his requested study.

Comments on Study

In the RSP, GLHA does not propose to conduct Mr. Spear's requested zooplankton study for the Ripogenus impoundment. GLHA states that Mr. Spear's argument for the requested study does not consider that landlocked salmon appear to be overpopulated in the impoundment and that populations of both fish species historically fluctuate. GLHA recognizes that rainbow smelt, which are not endemic to the West Branch, are an important food source for the landlocked salmon population that inhabits the Ripogenus impoundment, and that the volatile predator-prey relationship between the two species has been an on-going statewide concern for managing landlocked salmon fisheries for decades.[41] Moreover, GLHA notes that after years of Maine DIFW monitoring of the Chesuncook Lake fishery, Maine DIFW concluded that the depressed Ripogenus salmon fishery is due to an overabundance of landlocked salmon, which in turn has reduced the smelt forage base. Finally, GLHA notes that the phytoplankton and zooplankton studies conducted for the previous relicensing, which Mr. Spear references in his comments, were not designed to analyze the trophic food web relationships between zooplankton, smelt, and salmon, and they represent nothing more than a snapshot of the abundance and composition of the plankton community at that time and cannot serve as a stable or representative estimate of conditions in the impoundment.

Reply Comments

In his comments on the RSP, Mr. Spear argues that his requested study would provide the answers to most of the "problems" associated with the Ripogenus impoundment and downstream salmon fishery, and that the results would support the development of appropriate PM&E measures at the project for the next license term. Mr. Spear states that the origin of the smelt population is not important to the issue regarding the impoundment's smelt population. Mr. Spear states, without support, that Maine DIFW links the Ripogenus impoundment's salmon collapse to low smelt abundance,

[41] RSP at 6-18.

rather than an overpopulation of salmon in the impoundment. Mr. Spear indicates that his study request involves an inventory of the Ripogenus impoundment's phyto and zooplankton communities and smelt populations, which he states is a simple description of existing aquatic communities. He also clarifies that the requested study would involve multiple sampling events but would not be a multi-year study. Mr. Spear states that year-class fluctuations of smelt are typically between alternate years, not over a decade. Finally, Mr. Spear questions GLHA's assertion of overpopulation in the salmon population of the Ripogenus Impoundment, though he agrees that overpopulation occurs in some lakes in Maine.

In comments on the RSP, the Camp Owners Associations states that it supports Mr. Spear's contention that lake drawdowns directly and indirectly affect smelt populations in the Ripogenus impoundment.

Discussion and Staff's Recommendations

Zooplankton are small, aquatic microorganisms in the water column that include crustaceans, rotifers, open water insect larvae, and aquatic mites.[42] They are an important intermediary component of the food web, transferring energy from primary producers to the larger invertebrate predators and fish that feed on them. Larval fish assemblages are influenced by the availability and species composition of prey, as well as by habitat availability (particularly cover vegetation in shallow littoral areas where they can avoid predation). Juvenile rainbow smelt typically inhabit shoreline areas that are 6 to 18 feet in depth and relatively warm.[43] Sub-adult, or young-of-year, smelt are found in the pelagic (open water) zones of lakes. Spawning occurs primarily in tributary streams but may occur along a lake's shoreline. Rainbow smelt are zooplanktivorous at small sizes of less than 5.9 inches, consuming copepods and cladocerans (e.g., *Daphnia* and *Bosmina*), while at larger sizes, greater than 5.9 inches, their diet includes benthic crustaceans, as well as larval and small fishes (Sheppard *et al.*, 2012).

As Mr. Spear points out, impoundment level fluctuations can negatively affect aquatic communities. However, food web interactions are dynamic and regularly changing. The food web balance can be affected by a number of factors, including, in addition to lake level fluctuations, water quality, competition, and predator-prey relationships. In this instance, we have no reason to suspect that any adverse effects on zooplankton are specifically and directly related to lake level management in the

[42] *See* https://www.epa.gov/national-aquatic-resource-surveys/indicators-zooplankton, access May 3, 2022.

[43] *See* https://nas.er.usgs.gov/queries/factsheet.aspx?SpeciesID=796, accessed May 3, 2022.

Ripogenus impoundment as asserted by Mr. Spear, and Mr. Spear provided no basis to support is contention.

Moreover, and as a general matter, to assess the trophic relationships in question in order to rule out any project-related effect on zooplankton would be an extensive and expensive exercise that would likely take multiple study seasons to complete [section 5.9(b)(7)]. The limited information obtained, from one season of zooplankton sampling alone, would not be sufficient to answer the questions posed by Mr. Spear [section 5.9(b)(5)]. For these reasons, we do not recommend that GLHA be required to conduct the Ripogenus Impoundment Zooplankton Study requested by Mr. Spear.

**Study 17. 3-D Computational Flow Dynamics (CFD) Model Study**

Requested Study

FWS and Maine DMR request that GLHA conduct a 3-D Computational Fluid Dynamics (CFD) Model Study. The goal of the study would be to determine the potential hydraulic effects of the Penobscot Mills Project (i.e., East Millinocket, Dolby, Millinocket, North Twin, and Millinocket Lake Storage Developments) and the Ripogenus Project on: (1) the zone of passage for migratory fish near turbine discharges; and (2) flows and flow patterns immediately upstream of and downstream from each of the Projects' developments. Maine DMR states that this comprehensive understanding of hydraulic conditions at each powerhouse forebay is needed to create "safe, timely, and effective" upstream and downstream passage for Atlantic salmon, American shad, American eel, alewife, blueback herring, and sea lamprey on the West Branch (*see* Study Requests 22-24 below).

In their comments on GLHA's PSP, FWS and Maine DMR suggest that they would be willing to delay the requested CFD modeling until a future date. As an interim measure, FWS requested that GLHA collect headpond bathymetry data during the first study season, in anticipation of conducting the CFD modeling during the second study season. Maine DMR indicated that it would be amenable to delaying the requested modeling, provided the information from the study would be available to the Commission and stakeholders coinciding with the review of the draft license application or preliminary licensing proposal.

Comments on Study

In the RSP, GLHA does not propose to conduct FWS's and Maine DMR's requested CFD modeling study. GLHA states that the request for a CFD Model Study is equivalent to developing PM&E measures and is premature at this time. GLHA acknowledges that such an effort may be necessary at a future date. GLHA notes that the 2008 Strategic Plan for the Restoration of diadromous fishes to the Penobscot River

(Maine DMR & Maine DIFW, 2008) states that Atlantic salmon, American shad, and American eel historically used portions of the West Branch, but due to the lack of passage downstream at the time of preparation, West Branch passage of these species was not planned for the near future. There have been no new or amended restoration plans to define the timeline or strategies for sea-run fish on the West Branch. Moreover, GLHA indicates that, with the exception of American eel, sea-run fish (e.g., Atlantic salmon and American shad) do not have access to the West Branch.

Reply Comments

In its comments on the RSP, FWS, without elaboration, reiterates its request that GLHA conduct a CFD Model Study at each of the Projects' developments.

Discussion and Staff's Recommendations

The development of the requested CFD models would assist in determining potential effects of each of the project dams on hydraulic conditions for migrating fish in the West Branch and help inform fish passage designs and requirements at the projects. However, any potential fish passage measures to be implemented at the Projects would be dependent upon the schedules and effectiveness of passage enhancements at two downstream locations, including the Medway Project, which is located on the West Branch about 0.8 miles downstream from the Penobscot Mills Project's East Millinocket Development and the Mattaceunk Project No. 2520, which is located on the mainstem Penobscot River about 7 miles downstream from the confluence of the East Branch and West Branch and about 8 miles downstream of the East Millinocket Development. With the exception of upstream passage for American eel, there are currently no fish passage facilities at the Medway Project, for which the license expires in 2029. The Mattaceunk Project, for which a new license was issued on February 26, 2021, will not have improved upstream passage for alosines (via a new fishway), until 2037. Thus, the need for anadromous[44] fish passage at the Penobscot Mills Project is years in the future (and farther into the future for the further upstream Ripogenus Project). To undertake the CFD modeling exercise for anadromous fish species at this time would be premature [section 5.9(b)(5)].

With regard to American eel passage, one of the purposes of the requested CFD model study is to determine whether there are any upstream or downstream passage issues specifically associated with passage of eels at the Projects' dams. GLHA's

[44] Anadromous is a term that refers to a fish (e.g., salmon, alosines, sea lamprey) that ascend rivers from the sea to spawn.

stepwise approach would ensure that appropriate data is collected in a more cost-effective manner than requiring CFD modeling ($300,000)[45] at the onset [(section 5.9(b)(7)]. The ILP regulations contemplate the possibility of conducting additional studies, if the data collected in the first year do not meet the study objectives or indicate that further study is needed [sections 5.15(d) and 5.15(e)]. If the results of the required Upstream American Eel Passage Assessment – Presence, Distribution, and Relative Abundance of Juvenile Eel and Desktop Downstream Eel Passage Route and Survival Assessment show that passage is warranted, and more detail on hydraulic conditions for passage is needed, a specifically designed CFD Model Study could be considered after the ISR is filed.

**Study 20. Evaluation of Eel Size and Timing of Downstream Migratory Movement Study**

Requested Study

FWS and Maine DMR request that GLHA evaluate American eel size and downstream migratory movement at the Projects. The goals and objectives of the study are to understand the size and timing of downstream migrating eels, by quantifying and characterizing: (1) the size range of adult eels (silver eels) at, and moving downstream past, the Projects; and (2) the general migratory timing and presence of silver eels in the West Branch relative to environmental factors and operations of the Projects. FWS and Maine DMR state that the timing of downstream migration of silver eels is not defined for the West Branch, and there is no information about the size of the eels attempting to move downstream past the Projects. Therefore, the general effects of Project operations on eel survival to the ocean are unknown. FWS and Maine DMR state that this study would provide baseline information on river-specific downstream migration to predict when silver eels are expected to migrate downstream in the West Branch and facilitate the development of protection measures at the Projects, including changes in operation of the Projects to minimize passage risks.

The requested study would involve traditional active trapping (e.g., fyke or stow net sampling, weirs, or eel racks), or, alternatively, active and passive monitoring of migrant eels using hydroacoustic methods.[46] GLHA would need to identify at least two potential locations for sampling that would provide a route of downstream passage with a proximal bypass. The bypass would be equipped with a sampler so that fish could be concentrated/collected from the passage route and identified to species. Assuming a

[45] FWS and Maine DMR cite a cost of $50,000 for each CFD model. We assume a model would be needed for each of the projects' developments, including Ripogenus, North Twin, Millinocket, Dolby, East Millinocket, and Millinocket Lake Storage Dam.

[46] Passive monitoring would require verification of potential acoustic targets with some level of active (collection) or visual (optical or acoustic video) sampling.

combination of passive and active sampling, adult, silver eels would be assessed using methods similar to Haro *et al.* (1999), by continuously monitoring a fixed location at the Projects with hydroacoustics throughout the entire potential migratory season (mid-August through mid-December). An acoustic camera system would be operated concurrently with the acoustic monitoring to verify presence of eels and relative abundance of eel-sized hydroacoustic targets from the hydroacoustic data, as well as the sizes of the eels collected. Finally, each Projects' operations and environmental conditions would be monitored hourly, if possible, throughout the duration of the study.

Comments on the Study

In their comments on the PSP, FWS and Maine DMR reiterated their request for site-specific information on out-migrating eel size and timing, contending that the sources referenced in the PSP: (1) do not provide recent data; (2) are biased by collection methodology; and (3) are not representative of locations in the upper portion of the watershed.

In the RSP, GLHA does not propose to conduct FWS's and Maine DMR's requested downstream American Eel Passage Alternatives Study to evaluate eel size and timing of downstream migratory movement. GLHA contends that eel size and outmigration periods have been thoroughly studied in Maine rivers. GLHA argues that the results of its proposed Upstream American Eel Passage Assessment Study, coupled with: (1) the existing information on out-migration size and timing; and (2) the results of the proposed Desktop Downstream Eel Passage Route and Survival Assessment Study would provide adequate information on eel out migration. GLHA asserts that, based on expected low eel densities upstream of the Projects, actively sampling eels would be expensive and unlikely to provide an adequate sample size to obtain information on timing and population size and distribution.

Reply Comments

In its comments on the RSP, FWS, without elaboration, reiterates its request that GLHA conduct a study to evaluate American eel size and timing of downstream migratory movement.

Discussion and Staff's Recommendation

As previously stated, eel have been documented in the Projects' impoundments, but are thought to occur in limited numbers due to the Projects' location in the watershed

and the lack of eel passage at the Mattaceunk Project[47] located on the mainstream Penobscot River. Thus, operation of the Projects could affect survival of out-migrating silver eels from the West Branch.

The timing and size of out-migrating silver eels has been well studied in Maine. For example, Haro *et al*. (2003) characterizes run timing of out-migrating American eels in Maine as occurring from early September to early November, with the peak occurring during September 15 and October 15. Shepard (2015) indicates that eel out-migration in Maine occurs from August through October, with peak passage occurring in response to high river flows. In males, silvering happens at a size of about 14 to 16 inches, while silvering females are generally larger than 16 inches, and often exceed 39 inches. Based on commercial catch data from the Penobscot River tributaries, Weaver *et al*. (2021) found that out-migrating silver eels move most frequently when river discharge is greater than average. The maximum daily eel catch was observed at a water temperature of 60.8 °F. Weaver *et al*. (2021) also reported a negative relationship exists between eel catch and moon phase with catch higher during the new moon phase and decreasing towards the full moon phase.

The relatively recent information described above should be sufficient to evaluate the size and timing of out-migrating eels in the Penobscot River basin [section 5.9(b)(4)]. With the expected low density of eels, it would be very difficult and costly to acquire data significantly better than that already available [section 5.9(b)(7)].[48]

The required Upstream American Eel Passage Assessment Study, which incorporates the eDNA approach suggested by Maine DMR, if successful in its pilot year, should be sufficient to gain a better understanding of the current distribution and relative abundance of American eels upstream of the Projects. This information is currently lacking for the West Branch. GLHA's approach to addressing downstream eel migration project effects is reasonable. Given that the ILP regulations contemplate the possibility of conducting additional studies, if the data collected in the first year indicate that further study is needed [sections 5.15 (d) and 5.15(e)], the need for additional study of downstream eel migration in the West Branch can be considered after filing of the ISR. For the above reasons, we do not recommend requiring that GLHA carry out FWS's and Maine DMR's requested Evaluation of Eel Size and Timing of Downstream Migratory Movement Study.

---

[47] Upstream eel passage would be installed and operational at the Mattaceunk Project by June 1, 2023. *See* accession numbers 20211119-5211 and 20210817-5102.

[48] FWS and Maine DMR estimate the cost of their requested 2-year study to be $100,000. This estimate could increase if the number of eels sampled in accordance with the requested study design were insufficient to characterize the timing and size of out-migrating eels in the West Branch.

**Study 21. Downstream American Eel Passage Alternatives Study**

Requested Study

FWS requests that GLHA conduct a Downstream American Eel Passage Alternatives Study. The goal of the study is to determine conceptual options, and expected performance, for improved downstream passage that reduces delay, increases passage efficiency, and enhances survival for downstream migrating adult eels as they attempt to pass Ripogenus Dam, and the North Twin, Millinocket Lake Storage, Millinocket, Dolby, and East Millinocket Developments.

FWS's Downstream American Eel Passage Alternatives Study would consist of: (1) reviewing existing downstream fish passage technologies that meet FWS fish passage criteria (FWS, 2019), and (2) preparing conceptual engineering designs of downstream fish passage options. The expected performance of each alternative would be included in any report developed for the study. FWS states that data derived from this study would: (1) facilitate the evaluation of various alternatives to providing downstream eel passage at the Projects; (2) inform the Commission's licensing process; and (3) contribute to the development of an administrative record to support development of protection and enhancement measures for American eel.

Comments on Studies

In the RSP, GLHA does not propose to conduct FWS's requested Downstream American Eel Passage Alternatives Study. GLHA suggests that eel occur in limited numbers in the Projects' waters due to: (1) the Projects' relative location high in the watershed; (2) the abundance of eel habitat that exists in the East Branch and mainstem Penobscot River; and (3) the lack of upstream passage at the Mattaceunk Project. GLHA reports that only a small number of eels were observed from 2004 to 2015 at the downstream Medway Project . GLHA argues that FWS's requested downstream American eel passage alternatives study equates to the development of PM&E measures, which is premature at this time.

Reply Comments

In its comments on the RSP, FWS, without elaboration, reasserts its request that GLHA conduct a Downstream American Eel Passage Alternatives Study.

Discussion and Staff's Recommendation

GLHA is required to conduct an Upstream American Eel Passage Assessment Study for the Penobscot Mills Project and a Desktop Downstream Eel Passage Route and Survival Assessment Study for the Ripogenus and Penobscot Mills Projects. These required studies would document the relative densities of juvenile eels throughout the system, as well as characterize the downstream passage availability and survivability of the existing Projects' structures and operations, which would help inform downstream eel passage needs at the Projects. Until information on the densities of eels at the Projects and the effects of existing structures, if any, on downstream passaged is obtained, we have no basis for recommending an assessment of potential downstream eel passage options and related design considerations. Following the ISR meeting, stakeholders can propose to modify the study plan, or propose new information gathering or studies [sections 5.15(d) and 5.15(e)]. Therefore, we do not recommend that GLHA be required to conduct a downstream American eel passage alternatives study during the 2022 study season.

**Studies 22 and 23. Upstream Fish Passage Alternatives Study and Downstream Fish Passage Alternatives Study**

Requested Studies

Maine DMR requests that GLHA conduct upstream and downstream fish passage alternatives studies. The goal of the Upstream Fish Passage Alternatives Study is to determine conceptual options and the expected performance for passage structures that would provide "safe, timely, and effective" upstream passage for upstream migrating fish in the West Branch. The goal of the Downstream Fish Passage Alternative Study is to determine conceptual options and the expected performance for improved downstream passage that would reduce delay, increase passage efficiency, and increase survival for downstream migrating fish in the West Branch. Maine DMR asserts that access to the historic habitat in the West Branch is important to achieving the management goals for Atlantic salmon, American shad, alewife, blueback herring, and sea lamprey, and that effective upstream and downstream passage is critical to the restoration of these species to the West Branch. Maine DMR notes that, with the exception of an upstream ladder at the North Twin Development, the Penobscot Mills Project developments and Ripogenus Dam lack upstream and downstream fish passage structures to allow fish access to upstream habitat and safely pass back downstream.

Maine DMR's upstream and downstream fish passage alternatives studies would consist of: (1) a review of existing upstream and downstream fish passage technologies that meet FWS fish passage criteria (FWS, 2019); and (2) conceptual engineering designs of upstream and downstream fish passage. Maine DMR states that the information derived from the upstream and downstream fish passage alternatives studies would: (1) facilitate an evaluation of fish passage alternatives at the Projects; (2) inform the

Commission's licensing process; and (3) contribute to the development of an administrative record to support PM&E measures for Atlantic salmon, American shad, alewife, blueback herring, and sea lamprey.

Comments on the Studies

In the RSP, GLHA does not propose to conduct Maine DMR's requested upstream and downstream fish passage alternatives studies. GLHA states that the Projects' waters are currently managed by Maine DIFW as a resident coldwater fishery for landlocked Atlantic salmon and brook trout.[49] GLHA also states that the West Branch is not an immediate priority for restoration of Atlantic salmon, alosines, and sea lamprey (Maine DMR and Maine DIFW, 2008), nor does the West Branch contain any designated critical habitat for Atlantic salmon and that access is not essential to the recovery of the species. Finally, GLHA notes that the Medway Project, which is located on the West Branch less than a mile downstream from the East Millinocket Development, does not have fish passage structures for Atlantic salmon, alosines, and sea lamprey, and likely would not have such facilities until the upstream fish passage facility at the Mattaceunk Project, located on the mainstream Penobscot River, is constructed and operational (anticipated in 2037). For these reasons, GLHA states that the requested upstream and downstream fish passage alternatives studies constitute PM&E measures and are premature at this time.

Discussion and Staff's Recommendation

As noted by GLHA, Atlantic salmon, alosines, and sea lamprey currently cannot reach the Projects, and likely would not have access to the West Branch until at least 2037, 15 years into the future. Therefore, because the noted species currently do not have access to the Projects and the extent to which these species would ultimately reach the Projects is speculative and will likely not be known for at least 15 years, we have no basis for recommending Maine DMR's requested upstream and downstream fish passage alternatives studies ([section 5.9(b)(5)].

**Study 24. Freshwater Mussel Survey**

Requested Study

FWS requests that GLHA conduct a Freshwater Mussel Survey in each of the project impoundments, the bypassed reaches, and in project-affected reaches downstream

[49] In its letter filed February 22, 2022, Maine DIFW indicated that any reintroduction of sea-run fish to the West Branch should be coordinated with Maine DIFW due to concerns with density-dependent interactions and introduction of invasive species to the Projects' waters.

from the dams and powerhouses (e.g., Upper Gorge, the Holbrook Side Channel, the West Branch Penobscot River downstream from Stone Dam, and Millinocket Stream). The goal of the study is to determine which freshwater mussels inhabit project-affected areas. The specific objective of the surveys is to determine the species composition, distributions, and abundances of freshwater mussels, including the state-listed brook floater,[50] yellow lampmussel, and tidewater mucket. FWS recommends the use of snorkel or dive equipment to perform the surveys, depending on the depth of water. FWS states that such surveys are needed because there is limited information in the PAD on the distribution and abundance of freshwater mussels in the vicinity of the projects. FWS notes that, according to the PAD, the last freshwater mussel survey was performed in limited sections of the West Branch, and was undertaken in 2009 by Maine DIFW. FWS states that the mussel survey results are needed to conduct an effects analysis and to develop reasonable and prudent conservation measures, as well as PM&E measures under the Endangered Species Act.

Comments on the Study

In its comments on the PSP, FWS requests that the Commission require this study as requested, adding that water level fluctuations and drawdowns associated with hydropower operations can decrease the amount of habitat available to mussels and can cause mortality to any mussels that may be exposed as a result of such operations.

In the RSP, GLHA does not propose to conduct FWS's requested mussel surveys. GLHA states that extensive mussel survey data are available for West Branch watershed from Maine DIFW's surveys during the 1990s and 2000s. GLHA reports that the surveys include areas where aquatic habitat is directly affected by the Projects' operations (e.g., riverine reaches immediately upstream of, and downstream from project facilities and in a number of the project impoundments. GLHA asserts that FWS's study request does not adequately define the methods to use in performing the surveys. Finally, GLHA contends that, based on Maine DIFW's survey data, there is no evidence the Projects are affecting mussel populations and distribution in the West Branch, and that FWS's request for mussel surveys constitutes basic research that is not likely to inform the development of license conditions.

Reply Comments

In its comments on the RSP, FWS, without elaboration, reasserts its request that GLHA conduct mussel surveys in each of the project impoundments, the bypassed reaches, and in project-affected reaches downstream from the dams and powerhouses.

[50] The brook floater is a priority at-risk species for FWS.

Discussion and Staff's Recommendation

The relative immobility of mussels makes them vulnerable to water level fluctuations associated with hydroelectric projects. As indicated above, Maine DIFW performed mussel surveys in the West Branch basin between 1996 and 2009, including in areas upstream of, and downstream from, the Projects, the Projects' impoundments, and in riverine reaches affected by the Projects' operation. Additional work has been done since that time (Maine DIFW, 2022) [section 5.9(b)(4)]. As documented in the PAD (*see* Table 5.4-13), Maine DIFW's surveys indicate that seven of the ten mussel species known to occur in Maine exist in the West Branch, including the triangle floater, creeper, eastern floater, eastern elliptio, eastern lampmussel, as well as the state-threatened brook floater, tidewater mucket, and yellow lampmussel. There are no federally listed species known to occur in the West Branch basin. While not all of the Projects' areas have been surveyed, it is reasonable to assume that if appropriate habitat and host species existed, mussels would be present in the unsampled areas and those mussels would be subject to water level fluctuations that occur during normal operations and maintenance activities.

FWS's recommendation that the surveys be done using snorkel or dive equipment, depending on the depth of water, does not provide sufficient detail to develop a study of potential project effects on mussels [section 5.9(b)(5)].

FWS asserts that recently collected mussel distribution and abundance information is needed to evaluate the Projects' effects on mussels and mussel habitat. However, as shown in the 10 years of operations data (included in Appendix S of the RSP) the operation of the Projects does not appear to have changed fundamentally since 2009. Therefore, the existing mussel survey data is sufficient to evaluate potential effects of the Projects' operations on mussels, and to inform the need for license conditions to protect mussels and their habitat in the West Branch [section 5.9(b)(5)].

For the reasons explained above, we do not recommend that GLHA conduct FWS's requested Freshwater Mussel Survey.

**Study 30. Common Loon Productivity Assessment**

Requested Study

Maine DIFW requests that GLHA conduct a Common Loon Productivity Assessment for the Millinocket Lake Storage and North Twin impoundments. The goals of the study are to: (1) evaluate common loon nesting success; (2) determine if Penobscot Mills Project operations affect loon productivity; and (3) assess causes of nest

failure to determine if these failures are influenced by project operations.[51] Maine DIFW's study would involve standard survey methods,[52] including weekly surveys by boat beginning in mid- to late-May and continuing through July (Taylor and Evers, 2009).[53] Data collected during the surveys, depending on the timing within the loon nesting cycle, would include: (1) the number of territorial pairs; (2) the delineation of territory boundaries defended by those pairs; (3) the number and location of nesting attempts; (4) the causes of any nest failure; (5) observations of clutch size and number of chicks hatched; and (6) documentation of chick survival. Field work would be required to collect data on the presence/absence of territorial loon pairs. If territorial pairs exist, then at least two additional years of field work would be needed to determine fledging rates and the causes of any observed nest failure.[54]

Comments on Study

In the RSP, GLHA does not propose to conduct Maine DIFW's requested study. In lieu of the study, GLHA proposes to use information obtained from the Historical Operations Data Assessment, along with the existing data documented from the 10 years of common loon nest monitoring for the two impoundments, to assess historic annual water levels at both the Millinocket Lake Storage and North Twin impoundments during the common loon breeding season and evaluate the potential effects of project operations on loon productivity. This information would then be applied to the North Twin impoundment, as well as the Millinocket Lake Storage impoundment, to better understand common loon habitat conditions and nesting success. Additionally, GLHA proposes to use the Operations Model to evaluate alternative operating scenarios, including the impoundment elevations, to be considered for the new licenses. This information would be compared to historical operations data to understand if changes in

[51] In its comment on the PSP, Maine DIFW revised its initial study request, but reiterated the need for GLHA to provide clarification regarding actual headpond water level fluctuations during the common loon breeding season (May 15 – July 31). Maine DIFW requested that study details, including goals, methodology, and anticipated reporting requirements be clearly explained in the RSP.

[52] Standard survey methods were developed by the Loon Preservation Committee in New Hampshire and the BioDiversity Research Institute, and have been adopted by the Northeast Loon Study Working Group.

[53] Bi-weekly surveys may be needed to monitor chick survival, and nest searching may require walking portions of shoreline.

[54] If fledging rates are lower than 0.48 chicks per territorial pair, which is needed to support a stable and self-sustaining population, then annual monitoring and possibly a raft management plan or more stable water levels may be necessary.

operation may affect nesting loons on the Millinocket Lake Storage and North Twin impoundments.

Reply Comments

In its comments on the RSP, Maine DIFW states that it supports GLHA's proposed approach. However, Maine DIFW reserves the right to reiterate its request for an assessment of common loon productivity at the Millinocket Lake Storage and North Twin impoundments.

Discussion and Staff's Recommendation

GLHA's existing data on common loons in the Millinocket Lake Storage impoundment, as well as the Ripogenus impoundment, comes from an initial 2-year survey in 1998 and 1999, followed by annual monitoring of common loon nesting habitat and success from 2000 to 2010. GLHA filed biennial reports with the Commission, which include information on impoundment elevations during the nesting season. The final October 19, 2010, monitoring report provides a summary of the results from the 10 years of monitoring on the Millinocket Lake Storage impoundment. The report documented numerous natural nesting areas and relatively stable water surface elevations during the loon nesting season in the impoundment.

The existing license for the Penobscot Mills Project allows for up to 10 feet of fluctuations to water surface elevations in the Millinocket Lake storage impoundment. However, in the RSP GLHA indicates that it has primarily operated the Millinocket Lake Storage and North Twin impoundments at relatively stable water levels, near the full pond elevation, that are protective of common loons during their nesting season (i.e., less than 0.5-foot increase or 1-foot decrease in elevation during 28-day periods from June 1 through July 15). The Operations Model would provide information on impoundment water surface elevations under alternative operating scenarios, and this data could be compared to historical operations data to further understand how changes in operation may affect nesting loons on the North Twin and Millinocket Lake Storage impoundments [section 5.9(b)(6)]. Therefore, we do not recommend that GLHA conduct Maine DIFW's initially proposed Common Loon Productivity Assessment for the Penobscot Mills Project, and, instead, recommend GLHA proposed study. Following the ISR filing, stakeholders can propose to modify the study plan, or propose new information gathering or studies [sections 5.15(d) and 5.15(e)].

**Study 35. West Branch Penobscot River Creel Survey**

Requested Study

In comments on the PSP (letter dated November 9, 2021), Edward Spear requests that GLHA conduct a creel survey on the West Branch of the Penobscot River to determine daily and annual angler use, effort, catch, method (e.g., drift boat, other watercraft, wading, etc.) and location of anglers fishing along the river between Ripogenus Dam and the base of Pockwockamus Falls. Mr. Spear requests that GLHA follow the methods employed in the 1978 creel surveys conducted during the previous relicensing effort.

Comments on Study

In the RSP, GLHA states that the 1978 creel surveys were used to collect data to inform its proposal for constructing a new dam (Big A) on the West Branch, downstream from the Ripogenus Project. The resulting creel survey data were also used in the last Ripogenus Project relicensing. At present, Maine DIFW conducts annual creel surveys in the West Branch of the Penobscot River, both formally (i.e., winter creel surveys) and informally (survey boxes). Further, as part of the Water Quality Study, GLHA proposes to compile and synthesize fisheries data in the Ripogenus Project area, including any recent creel survey data that may not have been discovered during development of the PAD. Therefore, GLHA contends that additional creel surveys are unnecessary.

Discussion and Staff's Recommendation

During the ILP's study period, Maine DIFW would conduct periodic creel surveys in the West Branch, which GLHA would compile and synthesize in support of its license applications. Further, as described in staff's recommended modifications to the Recreation Study, we recommend adding questions about fishing activities to the survey of recreation users. Because the Maine DIFW's surveys and data collected during the Recreation Study would provide information about angling at the Projects, additional creel surveys of the West Branch are not necessary at this time [section 5.9(b)(4)]. Therefore, we do not recommend that GLHA conduct the creel surveys requested by Mr. Spear.

# APPENDIX D

## ENVIRONMENTAL JUSTICE STUDY METHODOLOGY

To address the potential effects of continued operation and maintenance of the Ripogenus and Penobscot Mills Hydroelectric Projects (Projects) on environmental justice communities of concern, please prepare an Environmental Justice Study Report that provides the following:

a) A table of racial, ethnic, and poverty statistics for each state, county, and census block group within the geographic scope of analysis. For the Projects, the geographic scope of analysis is areas within 1 mile of the project boundaries. The table should include the following information from the U.S. Census Bureau's most recently available American Community Survey 5-year Estimates for each state, county, and block group (wholly or partially) within the geographic scope of analysis:
    i. Total population;
    ii. Total population of each racial and ethnic group (i.e., White Alone Not Hispanic, Black or African American, American Indian and Alaska Native, Asian, Native Hawaiian and Other Pacific Islander, some other race, two or more races, Hispanic or Latino origin [of any race]) (count for each group);
    iii. Minority population including individuals of Hispanic or Latino origin as a percentage of total population;[1] and
    iv. Total population below poverty level as a percentage.[2]

The data should be collected from the most recent American Community Survey files available, using table #B03002 for race and ethnicity data and table #B17017 for low-income households. A template table is provided below.

[1] To calculate the percent total minority population, subtract the percentage of "White Alone Not Hispanic" from 100 percent for any given area.

[2] To calculate percentage of total population below poverty level, divide the total households below the poverty level by the total number of households and multiply by 100.

b) Identification of environmental justice populations by block group, using the data obtained in response to part a above, by applying the following methods included in EPA's *Promising Practices for EJ Methodologies in NEPA Reviews* (2016).[3]

   i. To identify environmental justice communities based on the presence of minority populations, use the "50 percent" and the "meaningfully greater" analysis methods. To use the "50 percent" analysis method, determine whether the total percent minority population of any block group in the affected area exceeds 50 percent. To use the "meaningfully greater" analysis determine whether any affected block group affected is 10 percent greater than the minority population percent in the county using the following process:

      1. Calculate the percent minority in the reference population (county)
      2. To the reference population's percent minority, add 10 percent (i.e., multiply the percent minority in the reference population by 1.1)
      3. This new percentage is the threshold that a block group's percent minority would need to exceed to qualify as an environmental justice community under the meaningfully greater analysis method.

   ii. To identify environmental justice communities based on the presence of low-income populations, use the "low-income threshold criteria" method. To use the "low-income threshold criteria," the percent of the population below the poverty level in the identified block group must be equal to or greater than that of the reference population (county).

c) A map showing the Projects' boundaries and location(s) of any proposed project-related construction in relation to any identified environmental justice communities within the geographic scope. Denote on the map if the block group is identified as an environmental justice community based on the presence of minority population, low-income population, or both.

d) A discussion of anticipated project-related effects on any environmental justice communities for all resources where there is a potential nexus between the effect and the environmental justice community. Examples of resource effects may include, but are not necessarily limited to, project-related effects on: erosion or

[3] Available online at https://www.epa.gov/sites/default/files/2016-08/documents/nepa_promising_practices_document_2016.pdf.

sedimentation of private properties; groundwater or other drinking water sources; subsistence fishing, hunting, or plant gathering; access for recreation; housing or industries of importance to environmental justice communities; and construction- or operation-related air quality, noise, and traffic. For any identified effects, please also describe whether or not any of the effects would be disproportionately high and adverse.

e) If environmental justice communities are present, please provide a description of your public outreach efforts regarding your project, including:
    i. a summary of any outreach to environmental justice communities conducted prior to filing the application (include the date, time, and location of any public meetings beyond those required by the regulations);
    ii. a summary of comments received from members of environmental justice communities or organizations representing the communities;
    iii. a description of information provided to environmental justice communities; and
    iv. planned future outreach activities and methods specific to working with the identified communities.

f) A description of any mitigation measures proposed to avoid and/or minimize project effects on environmental justice communities.

g) Identification of any non-English speaking groups, within the geographic scope of analysis, that would be affected by the project (regardless of whether the group is part of an identified environmental justice community). Please describe your previous or planned efforts to identify and communicate with these non-English speaking groups, and identify and describe any measures that you propose to avoid and minimize any project-related effects non-English speaking groups.

h) If new construction is proposed, identification of sensitive receptor locations (e.g., schools, day care centers, hospitals, etc.) within the geographic scope of analysis. Show these locations on the map generated in step c. Provide a table that includes their distances from project facilities and any project-related effects on these locations, including measures taken to avoid or minimize project-related effects.

This study should be conducted in consultation with the Penobscot Indian Nation and other relicensing stakeholders who express interest. When you file your final study report with the Commission, please include documentation of any consultation you conducted with entities that expressed interest in environmental justice, copies of their

comments, and an explanation of how you have addressed their comments in your final response.

RE: Penobscot Mills Project, FERC No. P-2458

Comments on Study Plan Determination for the Ripogenus Hydroelectric Project and the Penobscot Mills Hydroelectric Project Study 15, North Twin Impoundment Tributary Access Study

Dear Secretary Bose,

FERC staff rejected the above referenced, very reasonable MeDIFW study request. *"We do not recommend the Landlocked Salmon Radiotelemetry Study requested by Maine DIFW".* The grounds and logic used in this rejection are ill founded. The FERC endorsed study will not provide useful information and may not even confirm spawning information provided in the 1991 application. If radio tagging is not included in the study plans, I recommend MeDIFW withdraw from Study 15.

*"GLHA asserts that, while tracking seasonal movements of salmon via radiotelemetry and collecting landlocked salmon population dynamics data would be useful fishery management information, it is not necessary to assess the effects of project operation on landlocked salmon spawning*." As in many cases this is the Licensee's opinion, and, as usual, not fact based. Fishery management is based on project operation. If spawning and subsequent juvenile production is impacted by high or low lake levels, then these project operations created events directly impact fisheries management.

FERC states "*A radiotelemetry study could track movement of salmon and potentially detect spawning behavior in these areas (emphasis added)."* Salmon behavior is the key. Beginning in September, salmon move looking for suitable spawning areas, often the natal area. This is not an instantaneous process and often takes time. The natal spawning area may be unsuitable due to change in flow. Without radio tagging and tracking data (behavioral) pre spawning movement will be unknown. Salmon may visit two or more possible spawning areas and these events will remain unknown.

The exact method of determining possible lacustrine spawning areas is a mystery. Salmon are known to spawn in depth of up to four feet (See FERC P-3779 application). The method of determining salmon concentrated in these deeper lake areas is confusing. One possibility is scuba gear as the pre spawning salmon are apt to be ten feet or more below the surface.

Key known spawning areas are Nahmakanta Stream and the West Branch upstream of the North Twin Impoundment. FERC staff fails to explain how a North Twin Impoundment salmon will be differentiated from a West Branch salmon when observed at or near a West Branch spawning area. An impossible task without radio tagging.

FERC states "*Landlocked salmon are found infrequently downstream from North Twin Dam and are believed to be incidental dropdown individuals"* The 1991 Penobscot Mills Application reports an average catch of 200 legal size landlocked salmon below the North Twin Facility. Thus, there is no

foundation for FERC's statements. NO current fishery data has been provided and the status of the North Twin tailwater fishery is unknown. This statement is incorrect and biased toward the Licensee arguments.

FERC references "cost". NO mention of what these costs might be. What is the environmental cost of not performing this study? The Licensee is a multinational corporation that benefits from using a Maine resource to sell power though ISONE, a regional market. Given the magnitude of these licenses and the Licensee's resources, the minimum cost of this study should not be used as an excuse.

For the reasons outlined above, FERC staff should revisit the North Twin Impoundment Tributary Access Study Plan and make the necessary revisions.

Thank you for the opportunity to comment.

Re: The Ripogenus Projects P-2572, FERC May 13, 2002 Filing; Study Plan Determination for the Ripogenus Hydroelectric Project and the Penobscot Mills Hydroelectric Project

Study Response 16. Ripogenus Impoundment Zooplankton Study

In the strongest language possible, I object to FERC's refusal to implement a study of the Ripogenus Impoundment zooplankton community. In rejecting this requests FERC ignores the extensive peer reviewed literature-based evidence on zooplankton populations, assumes facts not in evidence, miss quotes my initial study request, ignores Maine Department of Inland Fisheries and Wildlife (MeDIFW) objectives for the Ripogenus Impoundment and the downstream West Branch and cites costs. For the reasons listed below, I request FERC reconsider its decision.

! In my January 27, 2022 filing (see attached) I provided peer reviewed information on relationships between zooplankton-juvenile smelt and landlocked salmon (salmon). This information was conclusive. The Licensee refuted my request for zooplankton studies with legal arguments, rather than science, simply because the science supported my arguments. FERC in its Study Plan Determination (SPD) used generic statements to concur with the Licensee. Without zooplankton sampling how will the "structure and function" of resident populations be determined?

The Licensee in the PAD and subsequent filings have submitted 30-40 year old data and supported this with legal arguments. Requests for studies are rebutted with more legal arguments rather than science. The Licensee says "believe us", we care about the resources. The Licensee continues with a list of protection, mitigation and enhancement measures, items they failed miserably to meet in 2021. It is time for FERC to give equal consideration to agency and stakeholder study request

FERC initial error was accepting the licensee's contention that "nothing has changed". Why believe the Licensee when that recent filings demonstrate project operations, namely impoundment drawdowns, have changed? The years of relatively stable base flows and lake levels are gone. Some of the impacts of these drawdown are known; MeDIFW has identified a collapsed salmon and juvenile smelt population, acres of dewatered shoreline and unusable boat docks and launching ramps, lack of connectivity between lake basins. Other impacts are yet to be defined. One such impact is the status of the zooplankton community, a major component of the food website. As pointed out in my January 27, 2022 filing, the zooplankton-juvenile smelt relationship is complex. FERC used my intellectually honest statement as an excuse to deny the study request. "Complex" is not a valid reason to reject a study request. FERC is speculating on possible study results. The literature is replete with evidence suggesting that project operations e.g., drawdowns and timing of drawdowns, is impacting zooplankton and juvenile smelt populations. A this point of licensing, science and the need for knowledge overweighs "policy" and legal arguments. Citing random events as possible reasons for declines in the juvenile smelt populations, almost certainly associated with zooplankton populations ignores science.

! FERC Staff cited facts not in evidence. FERC talks about the food web, and then refuses to address self-evident issues. MeDIFW has documented a Ripogenus Impoundment salmon population in collapse, a situation that has existed for 15-20 years. I concur and commend MeDIFW on their creel survey effort. *"Moreover, GLHA notes that after years of Maine DIFW monitoring of the Chesuncook Lake fishery, Maine DIFW concluded that the depressed Ripogenus salmon fishery is due to an overabundance of landlocked salmon, which in turn has reduced the smelt forage base."* The above FERC quote is incorrec*t, 1)* MeDIFW believes there is an <u>overabundance of subadult salmon</u> and has acted to increase the harvest of salmon less than 16 inches 2) MeDIFW monitors the salmon fishery rather than the fish assemblage. I spent most of my 25 year career studying the fisheries of the Ripogenus Project waters. As noted before, I strongly disagree with MeDIFW's conclusion. As there have been no juvenile smelt collections e.g., trawls, hydroacoustic, etc., there are simply NO data.

Another “data gap”, actually a black hole. Neither peer reviewed literature nor MeDIFW data bases support the contention that the salmon population has been “out-of-balance” for 15-20 years (coincidental to the Licensee change in operations) and that over population of subadult salmon is the cause. Thus, MeDIFW conclusion is simply an opinion that is totally based on salmon while ignoring the literature on juveniles smelt and zooplankton population. In fact, NO post 1991 information is available on either juvenile smelt or zooplankton populations. NONE. Basing a 30 year license on opinion while ignoring extensive peer reviewed literature is a clear violation of the NEPA policy. FERC states “*In this instance, we have no reason to suspect that any adverse effects on zooplankton are specifically and directly related to lake level management in the Ripogenus impoundment”.* FERC has more than an adequate “reason” to suspect “adverse effects”. How about the decline in the Ripogenus Impoundment salmon/smelt population that coincides with the Licensee’s change in project operations? The refusal of a zooplankton study outlined Response 16 contradicts the exiting peer reviewed literature.

! FERC misrepresented my initial study request. In the January 27, 2022 filing I stated “*If used in conjunction with other water quality sampling events the collection costs are minimal. Fine mesh plankton nets can be “towed” behind the boat used in sampling Ripogenus Impoundment basins. The Caribou basin should be included in zooplankton sampling. Data collected in 2022 can then be compared to studies conducted in 1981 (see tables below; Vol VIII 1991 Rip Application). Locations, timing and methods of the 1981 Ripogenus Impoundment zooplankton surveys can be found in Volume VIII of the 1991 license application*”. Thus, my request was both well founded and well defined.

FERC also misquoted my comment on the need for zooplankton populations Study(s). “*Mr. Spear references the poor quality of the impoundment’s zooplankton community, smelt population”.* As no plankton data are available for the last 38 years it would difficult to make a quantitative judgement on the status on any plankton population. My statement was based on extensive literature review and MeDIFW data and the knowledge that juvenile smelt are in short supply. The peer-reviewed literature continues to support my contention. FERC staff should review these reference as they provide a compelling case for zooplankton study.

- Failure to study Ripogenus Impoundment zooplankton populations impacts MeDIFW objectives for the Ripogenus Impoundment and most importantly the downstream West Branch. It appears that FERC concurs with the importance of juvenile smelt to the Ripogenus Project salmon population and the importance of zooplankton as a smelt food source. The 1996 EIS discussed at length the role of smelt drift in creating a world class salmon fishery in the river downstream of McKay Station. Thus, FERC agrees on the nexus of the Ripogenus Impoundment smelt population and the West Branch salmon population. Thus, it follows that the food source of Ripogenus juvenile smelt, zooplankton, is key to smelt drift abundance in the West Branch. Determining the status of the Ripogenus Impoundment zooplankton (and juvenile smelt) populations will enable MeDIFW to meet fisheries goals in the West Branch below McKay Station and return these waters to their former status of a "destination fishery".
- FERC uses "cost" in their denial of a zooplankton study. It states this without any mention of what that cost might be. My request for Plankton tows and analysis, these are not "big ticket" items. Given the Licensee international status and financial capabilities quoting "cost" is a bit of a stretch. The status of the smelt/zooplankton comminutes is impacting two former regional famous fisheries. Given the fisheries importance of Ripogenus Impoundment and West Branch downstream of McKay Station in the 1996 EIS, the small cost should not be an issue.

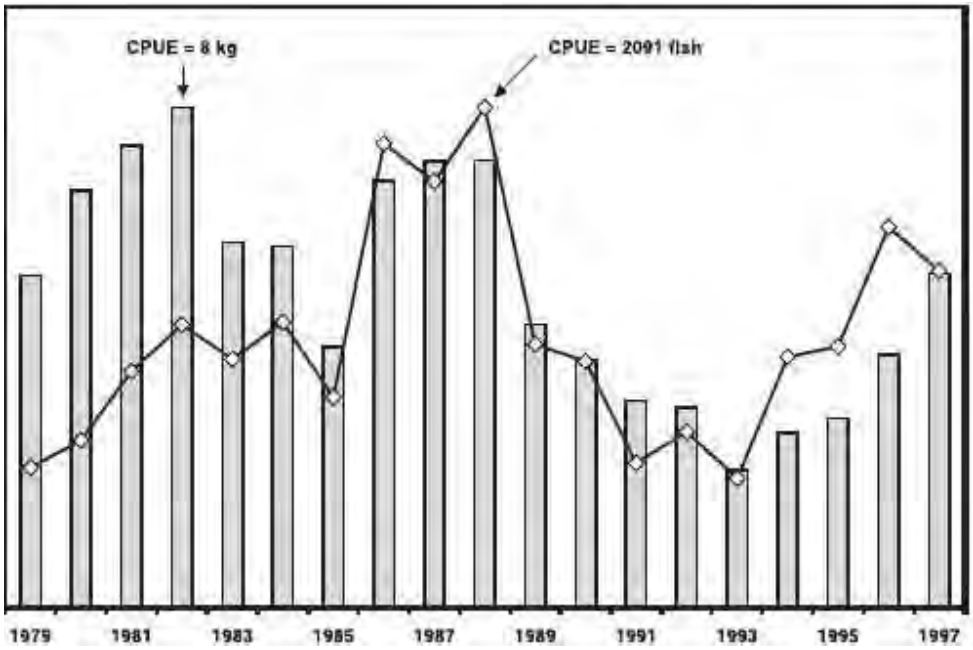
**Reference: Ripogenus Hydroelectric Project (P-2572-133)**
**RE:** A Study Request; The Need to Determine the Status of the Ripogenus Impoundment Zooplankton Population and its Relationship to Larval and Juvenile Rainbow Smelt (Osmerus mordax)

Operations of the Ripogenus Project have changed from the 1996 license conditions of relatively stable base flows and (following) rule curve (storage) guidelines. These flow and lake level changes have significantly altered the observable biotic communities, fish and macro invertrabrates as well as impacting guilds not readily visible e.g., planktonic. Little data exists, but the status of the Ripogenus Impoundment landlocked salmon (salmon) and rainbow smelt (smelt) populations is, as explained below, appalling. Information concerning planktonic communities of the Ripogenus Impoundment and West Branch of the Penobscot River below McKay Station (West Branch) is desperately needed. FERC staff, agencies and stakeholders require current data to make informed decisions.

The Maine Department of Inland Fisheries and Wildlife (DIFW) conducted surveys of the Ripogenus Impoundment landlocked salmon (salmon) fishery during 2018-2021. These salmon growth, food habitat and general abundance studies demonstrated a fishery in decline; adult salmon were fewer and in poor condition. DIFW cited the lack of young of the year (YOY)/Age I smelt as the problem. These small (2-5 inch) smelt are suitable in size as salmon prey. Age II and older smelt are generally too large to be useful prey items for adult salmon. Similar YOY smelt trends exist in the West Branch where salmon growth is well below 1980s levels and smelt are generally absent. To their credit DIFW responded to the depressed Ripogenus salmon fishery by increasing the harvest of sub adult and adult (>12 inches) salmon. The goal was to increase the Ripogenus YOY smelt population by reducing salmon predation, thus allowing the smelt population(s) to recover. This strategy has yet to prove successful. Peer

reviewed literature demonstrates that salmon predation on smelt is an unlikely cause of the continuous (10-15 years) lack of juvenile smelt.



There are NO current data on the growth and abundance of smelt, phytoplankton or zooplanktons population in the Ripogenus Impoundment. To date, attempts to reduce the Ripogenus salmon population have failed to rejuvenate the smelt forage base. DIFW has stated that angler effort is not at the level needed to reduce the adult salmon population. While angler harvest offer possibilities in rebuilding smelt populations, there are better alternatives. A review of journal articles demonstrates that lake level management is the likely cause of a depressed/altered zooplankton community that has resulted in a depleted juvenile smelt forage base over the last ten plus years. These reasons all involve the abundance and structure of zooplankton populations. The cause and effect of lake level management e.g., timing of drawdowns, depth, temperature and fluctuation/compression of the littoral zone, lack of connectivity (between basins) need to be explored.

Smelt are vital forage species and in some areas also a hook and line or dip net fishery. Smelt are well distributed throughout the Northeast, Midwest (Kircheis and Stanley 1981) and Northwest where they exist as the sub species, *O. dentex*,. Because of their role as both a forage and table fish; smelt abundance, prey selection and habitat preference have been well studied. Without smelt as prey salmon populations collapse and cease to provide a fishery (Havey and Warner 1970).

A 1981 summary by Maine research biologists Fred Kircheis (MeDIFW) and Jon Stanley (UMO Coop Fish Unit) reviewed smelt populations in Maine and other Lakes throughout the Northeast. Regarding variability in smelt population abundance/densities, they concluded that *"such fluctuation are usual and do not appear related to predator abundance, rainbow smelt fishing or disease." Rainbow smelt larvae require small zooplankton such as rotifers when they begin feeding, "unavailability of suitable size plankton might limit survival of larvae" (McCullough and Stanley, 1979)."* (Kircheis and Stanley 1981). The literature provides insight into a litany of factors determining smelt abundance and growth. Based on extensive review of the literature, the primary reason for a reduction in larval/juvenile smelt year class is cannibalism by age II and older smelt. Smelt are known to demonstrate alternate year class strength, often resulting from cannibalism as well as variable population densities resulting from predation or

loss of suitable zooplankton as forage. Stetter et al. (2007) reported cannibalism at between 38 and 95 percent of YOY year class strength. This cannibalism typically produces alternate smelt years classes where larval survival is poor the first year but strong the next year(s) (Lantry, B.F., and Stewart, D.J. 2000). He and Labar (1994) studying Lake Champlin smelt populations noted that gaps in year class strength could extend for three to five years. The figure below demonstrates smelt year class variability (Mills et al. 2003). These data are from the USA side of Lake Ontario.

**Fig. 6.** Indices of relative abundance ( ) and biomass (bars) of age-1 and older rainbow smelt for a 21-year period, 1978 to 1998 caught in trawl tows of 10-min duration in late May – early June in U.S. waters of Lake Ontario. Indices are 3-year running means standardized to the maximum stratified CPUEs (catch-per-unit-effort) indicated. The X axis represent indices of abundance and biomass (0.0-1.2)

As there has been no change in the condition in West Branch salmon in ten plus years and DIFW has found a similar trend in Chesuncook, the lack of smelt has not been a cyclic event. Thus, both over-predation (by salmon) and cannibalism must be dismissed as factors in the ten to fifteen year decline of Ripogenus Impoundment smelt populations.

Depending on age, smelt have different temperature and depth preferences. Rooney, R.C and Paterson, M.J. (2009) provide excellent summaries of smelt life history requirements at life stage and depth. From these summaries we know

that "*YOY smelt are eurythermal and are usually found along the shoreline in depths of 7-20 feet. Yearlings become pelagic and move to deeper cooler water at "middle depths in the pelagic zone" unless the epilimnion temperature exceeded 18°C, in which case they congregated just beneath the thermocline" (Appenzeller and Leggett 1995). "Following fall turn over YOY smelt move to deeper water (Urban and Brandt 1993). Age II and older smelt can be found in the littoral zone in the spring but as surface waters warm, are usually distributed in the profundal zone with water temperature ranging for 6-14 C and depths greater than 15 meters." (Nellbring 1989)*. O'Gorman et al. (2000) reported that "smelt were forced into deeper water when Lake Ontario was colonized by exotic *Dreissena* mussels" and prey was reduced in shallower water.

Smelt are dependent on zooplankton and favor "large" bodied prey (including Diptera e.g., midge) and plankton communities can change with season and lake basin. Sheppard et al. (2012) described smelt food preferences in a Manitoba lake. "The Diet of freshwater population of rainbow smelt is generally composed of copepods and cladocerans (including Daphnia spp., Eubismina and Bossmina) (Urban and Brandt, 1993; Hrabik et al., 1998; Beisner et al., 2003; Johnson et al., 2004)". Selectivity of zooplankton prey varies with smelt age (and size). YOY Smelt (larval smelt >30 mm) are dependent on zooplankton and without suitable prey, populations collapse. Hrabik et al. (1998) described calanoid copepods as "favored prey". Age I and older smelt favor larger prey. Karnitz, J (1992) studying Lake Oahe Plankton found "Rainbow smelt prey were significantly larger than mean size of zooplankton in the environment" and that feeding increased with water temperature.

Zooplankton species composition can very between lake basins. Zooplankton communities in Lake George differed between two basins. "Large bodies zooplankton species were favored over smaller size species. Daphnia pulicaria that were dominant in one basin and were generally absent in the other basin where Mysis relicta was the dominate smelt prey item" (Siegfried, C. 1987). *Mysis* was most important in rainbow smelt diets in Western Lake Superior where smelt were again reported to choose larger taxa. Johnson et al (2004) reported a shift in species from prior studies of the Lake Superior zooplankton communities. Johnson, B.M., and Goettl, J.P. (1999) studying Horsetooth Reservoir smelt predation on zooplankton found "during 1989–1994 the abundant rainbow smelt population apparently reduced April and May crustacean zooplankton

concentrations from historical levels of 40–80 organisms/L to less than 1.0 organism/L, and a switch occurred in the cladoceran species composition." In later years the smelt population declined and the zooplankton community rebounded. Other authors referenced declines in zooplankton abundance resulting from piscivorous predation. And while there were shifts in taxa, in all cases, zooplankton populations returned to prior levels.

The above paragraphs provide compelling evidence of the relation between the abundance, suitability and availability of zooplankton populations as prey as related to smelt abundance and survival. The collapse of the Ripogenus Projects zooplankton-smelt prey relationship has been long-term, perhaps fifteen years. The exact mechanisms that created depressed zooplankton and Juvenile smelt declines in the Ripogenus Impoundment are unknown, but they are directly related to lake level management. Loss of shallow embayments (as hatchling habitat), compressed or shifting littoral zones reduce or eliminate critical larval or YOY smelt habitat, thus favoring older (and larger) age classes that prefer deeper water. These same factors apply to zooplankton communities that may have changed to meet altered intra species competition, food sources (phytoplankton) or micro habitat needs: depth, temperature, light (Appenzeller, A .and Leggett, W. 1995, Emery, A.R. 1973).

The status of the Ripogenus plankton population(s) needs to be defined. Zooplankton surveys need to be included in Ripogenus Impoundment water quality studies recommended by MeDEP. If used in conjunction with other water quality sampling events the collection costs are minimal. Fine mesh plankton nets can be "towed" behind the boat used in sampling Ripogenus Impoundment basins. The Caribou basin should be included in zooplankton sampling. Data collected in 2022 can then be compared to studies conducted in 1981 (see tables below; Vol VIII 1991 Rip Application). Locations, timing and methods of the 1981 Ripogenus Impoundment zooplankton surveys can be found in Volume VIII of the 1991 license application. To "fill in data gaps", FERC needs to require similar studies as part of the MeDEP October 2021 Water Quality Study request.

Historically the Ripogenus Impoundment supported an excellent salmon fishery and the Impoundment's smelt population was exported downstream ("drift") through McKay Station where it created and then supported the "world class West Branch salmon fishery". DIFW filings have demonstrated that these fisheries have collapsed. Echoing earlier works of Havey and Warner (1970), the DIFW

2012 management plan states, “Without adequate numbers of smelts, salmon growth and condition can become poor, markedly reducing their value as a sportfish” (Maine Salmon Management Plan. 2012). Without the export/drift of smelt, the West Branch fishery will disappear. FERC needs to ensure these two unique fisheries are returned to 1980s levels described by FERC staff in the 1996 EIS.

Re: The Ripogenus Project P-2572. Two observed Article 406 Violation.

Article 406 requires a flow of 35 cfs for the period beginning June 1, continuing until October 15. At that time flows are increased to 65 cfs. I have seen no E-library filing that suspends Article 406. The Ripogenus Impoundment is "full". The Holbrook Bypass Channel spawning and incubation flow requirement of 65 cfs was willfully violated.

During the mornings of May 17 and 18, I observed low West Branch flows in the areas near the Big Eddy Campground. A check of the Safewaters website confirmed my observation, as when I checked the Safewaters website, the given flow was 1276 cfs (Flows were reduced in late afternoon and increased in the morning). Unfortunately, Safewaters does not provide archival data. As I noted in my May 9, 2022 filing, flows in the range observed earlier this week do not meet the Article 406 requirement of 65 cfs. This is a license violation.

While not a license violation, the Safewaters website listed flows for the week of May 16 as being in the range of "2400" and "2700" cfs (this information is no longer available on the Safewaters website). Thus, recreationists who planned to fish or boat West Branch were disappointed when they arrived only to find a "dry river". Ripogenus Project waters are warming, fish and aquatic community activity is increasing. Daily low flow events disrupt fish and aquatic insect activity as well as fishing opportunity.

Thank you for the opportunity to comment

TROUT UNLIMITED
MAINE COUNCIL

**Via online submission to: http://www/ferc.gov (cross-filed)**

Subject: **Maine Council of Trout Unlimited Comments on the Brookfield letter Response to Minimum Flow Complaints for the Ripogenus Project (P-2572) dated June 8, 2022**

Dear Secretary Bose:

On behalf of its six chapters and over 2,000 members, Maine Council of Trout Unlimited ("TU)" submits these comments on the Brookfield letter Response to Minimum Flow Complaints for the Ripogenus Project (P-2572) submitted by GLHA ("Brookfield" or "Operator") dated June 8, 2022.

**Background**

In its June 8, 2022 letter, Brookfield provided the information that FERC requested to investigate the flow excursion events that Brookfield itself had reported[1] and consequent violation of license Article 406 provisions noted by Ed Spear.[2] Brookfield states that these complaints are "without merit."[3] The contents of the Brookfield letter fail to show that Brookfield was operating the project in accordance with the applicable articles of the current license or basing water management on established plans. The Operator must bear some responsibility for the extended low flow excursions.

**Discussion**

As Brookfield states in its response to the TU complaint: "*the WUP is the basis for the licensed water management requirements (which are intended to balance public safety, recreational,*

[1] Brookfield letter Response to Minimum Flow Complaints for the Ripogenus Project (P-2572) submitted by GLHA dated June 8, 2022.
[2] Ed Spear letter dated May 9, RE: The Ripogenus Projects P-2572, Great Lakes Hydro America's April 29, 2022 Filing, Articles 402 and 406: Violations not Excursions? Ed Spear letter dated May 20, RE: The Ripogenus Project P-2572. Two observed Article 406 Violation.
[3] Brookfield letter Response to Minimum Flow Complaints for the Ripogenus Project (P-2572) submitted by GLHA dated June 8, 2022, page 4: "In summary, the complaints filed by Mr. Heinz and Mr. Spear alleging noncompliance with Article 402 of the Ripogenus Project license are without merit, as GLHA's water management actions at the Ripogenus Project during the recent severe drought conditions are fully justified and entirely in compliance with the Project license."

*environmental, and power generation needs) under which GLHA currently operates both Projects*."[4] Brookfield fails to explain where and how the balancing occurred. It goes on to list reasons why the plan is inadequate due to changes to storage capacity within the watershed:

> "*GLHA notes that while the 1991 WUP was developed to serve as a comprehensive and long-term management plan for the storage system, the WUP also did not anticipate that the subsequent (2004) FERC license for the upstream Storage Project (FERC No. 2634) would result in a substantial loss of available storage capacity in the West Branch of the Penobscot River drainage due to the following drawdown limitations:*
>
> *Canada Falls Lake (0.56 billion cubic feet [bcf] lost)*
>
> *Seboomook Lake (2.68 bcf lost)*
>
> *Penobscot Lake (0.06 bcf lost)*
>
> *Dole Pond (0.16 bcf lost)*
>
> *Loon Lake (0.46 bcf lost)*
>
> *Harrington Lake (0.01 bcf lost)*
>
> *Additional water storage on the West Branch has been lost since 1996 with the implementation of wetlands mitigation at Umbazooksus Lake (0.45 bcf lost) and the transfer of Nesowadnehunk Lake Dam to a stakeholder (0.42 bcf lost). All told, total storage capability on the West Branch has been reduced by nearly 5 billion cubic feet since the WUP was finalized in 1991, thereby hindering WUP-based water management in the West Branch drainage."*[5]

The above losses were agreed to by the previous operator who apparently believed that the storage capacity was manageable, these were not changes imposed by FERC or some other government organization. Loon Lake, Harrington Lake, Umbazookus Lakes and Dole Pond contributed little to overall storage and were scheduled for abandonment. Brookfield should have been well aware of these changes when it acquired the project about ten years ago.

Regardless of this, Brookfield is required to operate under the articles of the existing license. If these articles had become impossible for the operator to observe, the mechanism for addressing the problems exists:

> "*A description of how flow-related recreation will be monitored and effectiveness of the Water Use Plan will be reviewed every 10 years over the term of the project license*."[6]

The Brookfield response letter goes on to say:

> "*Finally, as part of its contractual obligations with ISO – New England, GLHA is required to perform a CCA (claimed capability audit) test each summer (and once every 3 years in the winter) by maximizing generation at its facilities for short periods of time. The 2021*

[4] Brookfield letter dated June 8, 2022, page 3.
[5] Ibid.
[6] Ripogenus License, Project Number 2572 Issued October 22, 1996, page 31.

*CCA test was performed at the Ripogenus Project on August 12, 2021, which resulted in a flow of 3,300 cfs for several hours, well above the minimum flow."*[7]

This is misleading in two respects: there were higher than needed releases unrelated to CCA test, and ISO New England is only concerned with power generation, not environmental compliance. Brookfield has submitted lake level and flow data that covers August 2021 and more.[8] Figure 1 shows average flows and impoundment level submitted by Brookfield; supporting data is provided as Attachment A. Maximum two-generator operations is 2400 cfs.[9] For significant periods during 2021, Brookfield operated three generators at McKay Station. There was no apparent attempt to fill the Ripogenus-Chesuncook Impoundment. Of additional concern it that the CCA tests were conducted in August, not earlier in the year when more water should be available in the watershed. Target lake levels in other projects Brookfield operates are typically set to occur annually on June first, the CCA tests should have been conducted prior to then.

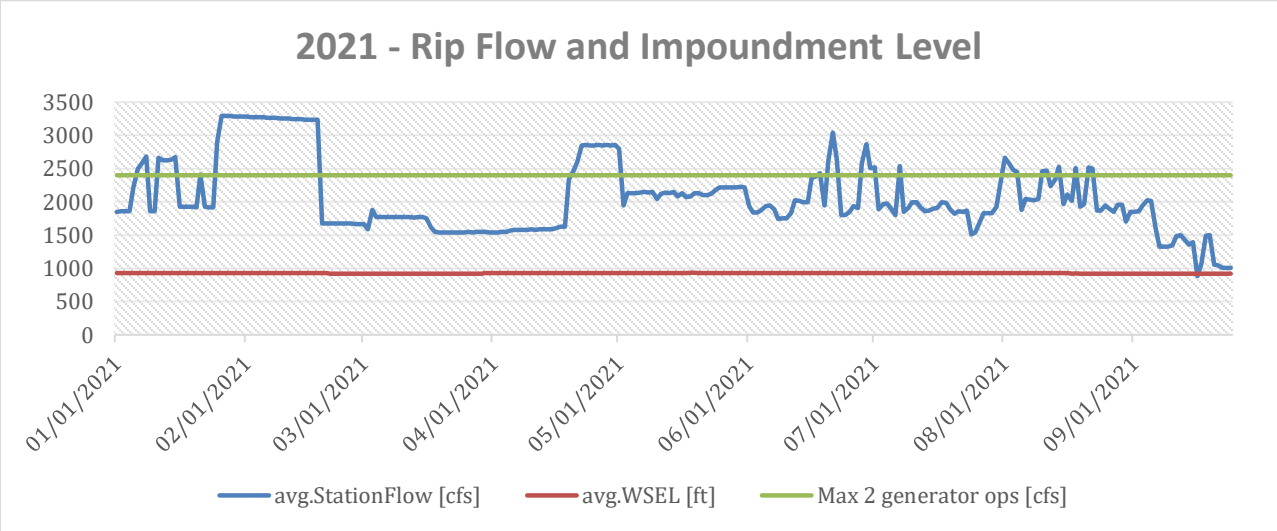

**Figure 1**

[7] Brookfield letter dated June 8, 2022, page 3.
[8] Ripogenus Revised Study Plan, Appendix S 2010-2021 - Daily Operations Data.
[9] Preapplication Document, Part 1 dated 2021, page 4-15, Table 4.3-1.

Figure 2 shows more granular flow data only from October 2021 to May 2022 also supplied by Brookfield.[10] Due to the size of the data set, we have not attached it. Examining the charts side by side, the blue lines showing flows are nearly continuous.

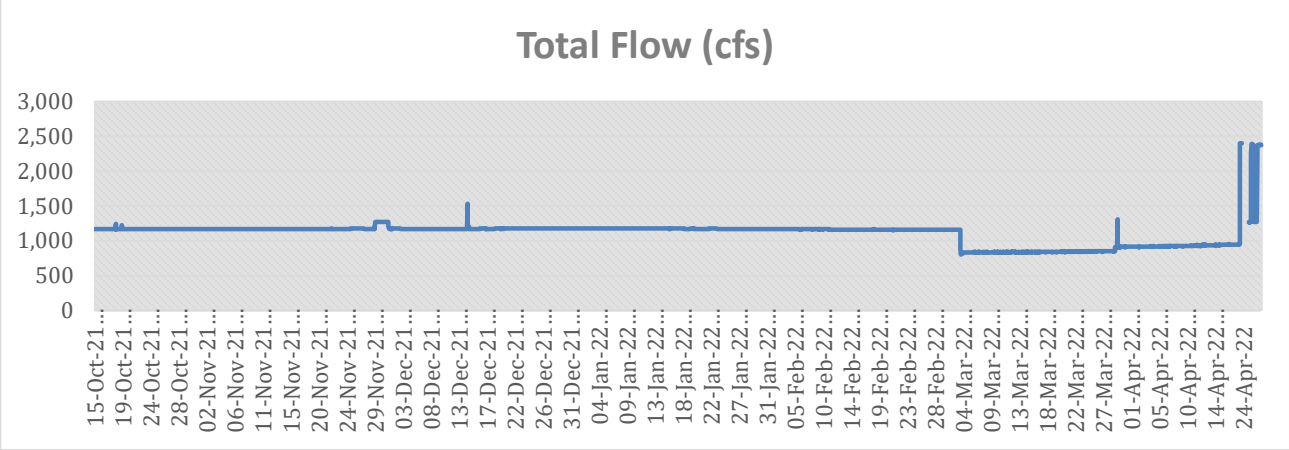

**Figure 2**

Contrast these charts with the Rule Curve for the project, EIS Figure D-1.[11]

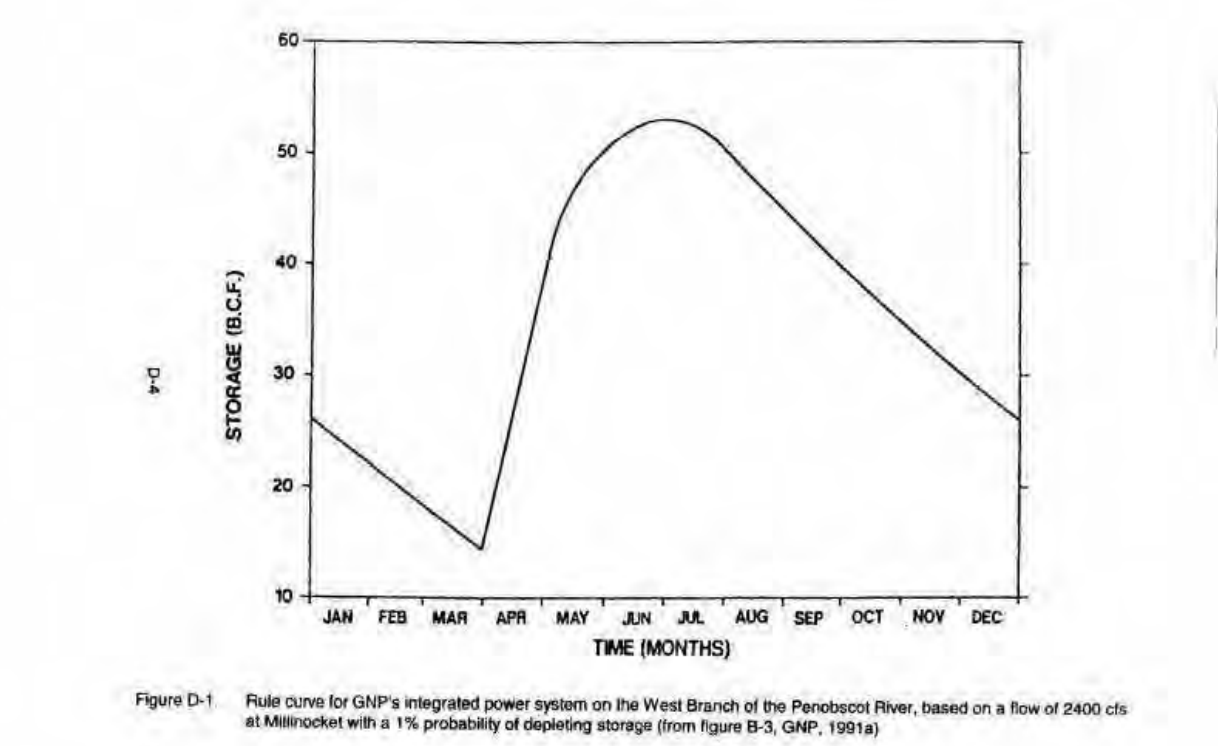

Figure D-1 Rule curve for GNP's integrated power system on the West Branch of the Penobscot River, based on a flow of 2400 cfs at Millinocket with a 1% probability of depleting storage (from figure B-3, GNP, 1991a)

[10] Brookfield letter dated June 8, McKay / Ripogenus Hourly Flows, page 9 and subsequent.
[11] Final Environmental Impact Statement, Upper Penobscot River Basin Volume 1, Appendix D.

Given the expectations indicated by the EIS approved Rule curve, TU does not see how continued peaking operations shown by Figure 1 and not discontinued by Brookfield that it was painfully apparent that minimum required spawning and incubation flows could not be maintained. Brookfield continues to blame dry conditions, but these conditions began in 2020. When Great Northern Paper operated the project, the power demands were based on the needs of the mills, not the grid which pays a premium for power supplied during peak periods. Brookfield has what may be the most modern hydro operations control center in the country located in Marlborough, Massachusetts. It was profit, not license requirements and certainly not the needs of the environment, which drove the operational decisions Brookfield made in 2021. Brookfield states that: "*…the complainants have the benefit of retrospectively criticizing GLHA's water management actions (as opposed to GLHA's need to implement water management actions in real time)* ..."[12] This statement ignores the fact that Brookfield had just dealt with dry conditions in 2020. Looking further back, 2016 was a dry year as well.

Brookfield did not note that the current license, in addition to minimum flow requirements for whitewater, spawning, etc. that were the focus of its flow excursion report[13] also considers other factors:

> *"These specified minimum flows shall be the minimum flows for each hourly period (measured on the basis of an hourly average). The recreational flow for each month from May through September shall be determined on the first day of each month. This determination shall be based on an analysis of Total Available Water, as described in the Water Use Plan presented in the application for new license filed December 17, 1991, pages 10-14 of Water Use Plan, Vol VII. The determination of "wet", "normal", or "dry" shall remain constant during the month based on the first day of the month classification. The range of "normal" available water represents the expected available water during normal hydrologic conditions. It is defined as the range between x-s and x+s, where "x" is the mean value and "s" the standard deviation. Based on a statistical analysis, total available water would be expected to be within this "normal" range two-thirds of the time, and outside of this range ("wet" or "dry" years) one-third of the time. The 15-year period of record from 1976 to 1990 shall be used for analysis of available water for the first 10 years of the license."*[14]

This was not the procedure followed by Brookfield when it chose to operate below spawning and incubation flows for an extended period. Analysis of hourly 2021 data may show additional license violations that cannot be detected using the minimum, average, and maximum data that Brookfield supplied with the Revised Study Plan.

[12] Brookfield letter dated June 8, page 1.
[13] Brookfield Ripogenus Project (FERC No. 2572-ME); Minimum Flow Excursion dated April 28, 2022.
[14] Ripogenus License, Project Number 2572 Issued October 22, 1996, page 31.

If this were not enough, Brookfield recently filed another significant Flow Excursion Report for the Penobscot Mills Project covering the period from March 4, 2022 to April 19, 2022, failure to maintain minimum flows.[15] Again, Brookfield blames dry conditions; again, Brookfield's operation of the Ripogenus Project must be considered a major factor.

It should be noted that currently most of Northern Maine including the project area is no longer in a drought condition as shown by this graphic.[16] White areas are not in a drought condition, yellow areas are abnormally dry, light orange area are experiencing moderate drought. The Ripogenus-Chesuncook Reservoir is full and Brookfield has resumed three generator operations.

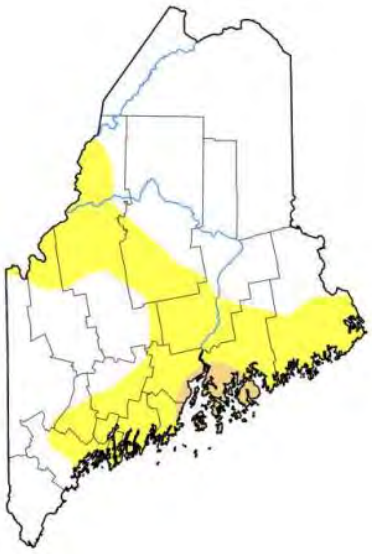

**Figure 3**

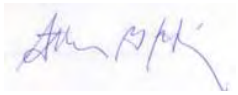
**Conclusion with Requests**

Maine TU Council appreciates the Commission's continuing attention to compliance issues involving the Ripogenus and Penobscot Mills Projects. Compliance history is a factor to be considered during the final licensing phase and we trust that the information contained in this filing will prove useful then as well as now.

The concerns stated by TU and Ed Spears are not "without merit" as Brookfield asserts. We ask that the Commission look further into Brookfield's flow excursions and attempt to find justification for any of the periods of three generator operations at McKay Station that occurred in 2021 on any but a profit basis.

Brookfield's response to FERC's request for flow data provided information but failed to provide convincing evidence or rationale to justify its reported flow excursions. Brookfield violated its license by the way it operated the Ripogenus Project in 2021 and 2022 because the need to go below established flow levels was due in part to poor water management and peaking operations. Due to the widespread harms this caused ranging from dewatering loons' nests and denying boating activities on Chesuncook Lake to adverse effects on salmonid spawning and incubation, enforcement action is justified. Brookfield has operated the project for ten years, so



[15] Brookfield letter dated April 28, 2022, Subject: Penobscot Mills Project (FERC No. 2458); Millinocket Development: Run-of-River and Minimum Flow Excursion.
[16] USGS U.S. Drought Monitor Data valid: June 21, 2022 at 8 a.m. EDT accessed at https://droughtmonitor.unl.edu/CurrentMap/StateDroughtMonitor.aspx?ME.

inexperience is not a valid excuse. TU reiterates its proposal that Brookfield be required to install a USGS compatible flow gage between McKay Station and Telos Bridge, and adds that a lake level gage be installed on Chesuncook Lake – both at Brookfield expense and to be maintained at Brookfield expense for the next ten years. We think that this would not only be appropriate but would also serve to prevent stakeholders filing low flow reports with FERC and necessitating investigations where if a USGS gage were present, no report would need to be filed.

Other concerns stated in TU's earlier filing[17] on this matter remain germane. TU reiterates its request for a copy of the Brookfield Renewable 11th Part 12D Independent Consultant's Safety Inspection Report and associated Potential Failure Mode Analysis Addendum for the Ripogenus Project under P-2572, Accession Number 20211229-5198, especially the addendum as twice previously requested.

We have cross-filed this document to dockets 2572-133 and P-2458-247 as it bears directly on the relicensings in progress. Brookfield cannot reasonably claim in compliance-related matters that it could not meet license flow requirements while claiming on relicensing studies-related matters that thirty-year-old studies are sufficient. When the Initial Study Report for the project is issued, it should be closely scrutinized to ensure that it contains adequate information on which to base future operational requirements and a Water Use Plan that will prevent future extended periods of low flow likely to have a detrimental effect on the fish and other aquatic life.

Sincerely and respectfully,

Stephen G. Heinz
Maine TU Council FERC Coordinator

VIA FERC Service

Kelly Maloney
Great Lakes Hydro American, LLC
150 Main Street
Lewiston, ME 04240-1398

Subject: Request for Additional Information Regarding Minimum Flow Deviations

Dear Ms. Maloney:

This letter is in reference to your April 28, 2022 filing, notifying the Federal Energy Regulatory Commission (Commission) of minimum flow deviations at the Ripogenus Hydroelectric Project No. 2572 between October 15, 2021 and April 18, 2022. Minimum flow requirements are established by Article 402 of the project license.[1] On May 10 and May 20, 2022, Mr. Ed Spear filed comments related to the deviations, as did Trout Unlimited on May 12, 2022. Mr. Spear's May 10 letter states that the low flows have affected salmon reproduction, and his May 20 letter alleges that additional deviations occurred on May 17 and 18. Trout Unlimited alleges that some of the minimum flow deviations could have been avoided by releasing less water in the months prior.

In order for Commission staff to complete our determination of your compliance with Article 402, please respond to the comments within 15 days of the date of this letter. In your response, please include hourly flow data from October 15, 2021 through April 18, 2022 as well as data from May 17 and 18, 2022. If you are unable to provide hourly data, please provide the highest resolution data available and a summary of your

[1] Order Issuing License (77 FERC ¶ 61,066), issued October 22, 1996.

flow monitoring methods.

Thank you for your cooperation. We look forward to your response, **due June 9, 2022**. If you have any questions regarding this letter, please contact me at (202) 502-8038 or alicia.burtner@ferc.gov.

Sincerely,

Alicia Burtner

Project No. 2572-136—Comments on FERC's May 26, 2022 letter to Great Lakes Hydro America, LLC. Continuing impacts associated with violation of License Article 406 Ripogenus Hydroelectric Project

This filing is in reference to FERC's May 26, 2022 letter to the Licensee requesting addition information. In my May 10 and 22, 2022 filings the focus was on Article 406 with a nexus to Article 402 (minimum flows). The violation of article 406 continued this past week (May 22-29, 2022). Flows were reduced to 1275 CFS at 5 PM and remained at that level until around 8AM the next morning. These lower flows continued to dewater landlocked salmon (salmon) spawning, incubation and nursey areas and aquatic communities' habitat in the Holbrook Bypass and downriver areas. Although there were few anglers, fishing opportunity was also impacted.

The attached photo of the Holbrook Bypass Chanel taken on May 27, 2022 during the daily 1275 cfs flow period clearly demonstrates the impact of low flow on aquatic habitat. Despite supplemental flow from an upstream brook, Bypass Channel velocities, depths and wetted widths were significantly reduced. The area pictured would likely support some juvenile brook trout production but not the intended purpose of juvenile salmon production as proposed by MeDIFW, MeDEP and FERC. Areas of dewatered shoreline were observable in all downriver locations.

While it appears that the March, 2022 agreement between the Licensee and resource agencies legally covered spawning flows, there are no filings that deal with emerging fry and subsequent young-of-the year and juvenile salmon habitat needs. The 2021 spawning season is over, the incubation period is about to end. The March minimum flow agreement wasn't "open ended". Surely Article 406 conditions remain in effect. Daily May 2022 McKay station flow reductions down to 1275 cfs levels have seriously impacted emerging salmon and brook trout, juvenile salmon habitat and aquatic insect behavior (pre "hatch" movement or "drift") and angler activity.

May, 2022 low flows e.g., 1275, have impacted juvenile salmon habitat in all areas downstream of McKay Station. Article 406 was designed as mitigation. The goal was to produce young-of-the-year salmon in the Holbrook spawning and nursey bypass channel and as an artifact, downstream habitats. Article 406 requires a flow of 35 cfs for the period beginning June 1, continuing until October 15. At that time flows are increased to 65 cfs. McKay Station flows of 1275 makes meeting either the 35 or 65 cfs a hydraulic impossibility. This must be a continuing violation of Article 406.

The Licensee boast of various flows as Protection, Enhancement and Mitigation measures. I argue that the Licensee bears the responsibility to support its claims and remain in full compliance of all License Articles. As we move though the licensing process, FERC needs to ensure that unnecessary low flows events do not disrupt threaten angling,fish and aquatic communities.

Thank you for the opportunity to comment.

***Electronically Filed***

**Subject: Ripogenus Project, FERC No. 2572; Response to Minimum Flow Complaints**

Dear Secretary Bose:

Great Lakes Hydro America, LLC (GLHA), licensee for the Ripogenus Project (Project) located on the West Branch of the Penobscot River in Maine, submits this letter in reply to Commission correspondence dated May 26, 2022, in which the Commission requests additional information regarding complaints filed on May 12, 2022 by Mr. Stephen Heinz, writing on behalf of the Maine Council of Trout Unlimited (TU), and by Mr. Edward Spear (on May 9, 2022 and May 20, 2022). Mr. Heinz and Mr. Spear alleged that the recent low fall and winter flows at the Project represented violations of minimum flow requirements at the Project.

On May 26, 2022, the Commission requested that GLHA respond to these allegations within 15 days (or by June 9, 2022), specifically in order for the Commission to determine GLHA's compliance with minimum flow requirements for the Project contained in Article 402. The Commission also requested that GLHA include hourly flow data from October 15, 2021 through April 18, 2022, as well as data from May 17 and 18, 2022.

**Minimum flow requirements**

As detailed in GLHA's October 14, 2021 and March 10, 2022 filings with the Commission responding to previous TU complaints at the Ripogenus Project, Article 402 of the Ripogenus Project license requires that minimum whitewater recreation flows of between 1,800 and 2,300 cfs be released from the Project between 08:30 and 17:00 hrs on a daily basis between May 1st and September 15th. From September 16th through October 1st, Article 402 requires minimum whitewater recreation flows of 2,200 – 2,300 cfs, but only on weekends from 08:30 – 17:00 hrs. Between June 8 and October 14, a minimum flow of 1,000 cfs is required on days and for hours outside of these whitewater release time periods.

Article 402 of the Ripogenus Project license also states in relevant part that, "*The licensee shall release from the Ripogenus Project into the West Branch of the Penobscot River below McKay Station the following minimum flows: Salmon spawning flows of at least 1,422 cfs or inflow, but not less than 1,300 cfs, from October 15 to November 15, and salmon incubation flows greater than 1422 cfs (or the spa blished for that year) from November 16 through June 7. These flows shall be e year in consultation with the U.S. Fish and Wildlife Service and Maine Depa Fisheries and Wildlife.*" However, Article 402 also states that "*Minimum flows may be modified if required by hydrologic conditions beyond the control of the licensee, upon mutual agreement between the licensee, the U.S. Fish and Wildlife Service, DEP, LURC, and DIFW.*"

Millinocket, ME 04462
www.brookfieldrenewable.com
Tel: 207.723.4341
Fax: 207.723.3948

Brookfield Renewable

Finally, Article 402 allows reduced minimum "outage" flows of 400 cfs during generating unit failures at McKay Station, and it specifies that all of the minimum flows specified in the Article *"shall be the minimum flows for each hourly period (measured on the basis of an hourly average)."*

Response to Low Flow Complaints

As detailed in GLHA's letter to the Commission dated March 9, 2022, a reduced minimum flow of 800 cfs was implemented at the Ripogenus Project on March 4, 2022 through consultation with the resource agencies[1] due to severe drought conditions in portions of the upper Penobscot River watershed. This followed the establishment (also through agency consultation) of a Project spawning and incubation flow of 1,100 cfs in October 2021 due to the drought and low water level conditions.

Although the complainants do not dispute the severe drought conditions that have plagued the upper Penobscot River drainage since 2020, they do allege that water mismanagement by GLHA (rather than hydrologic conditions) contributed to the need to reduce minimum flows at the Project. Mr. Heinz and Mr. Spear more specifically allege that GLHA mismanaged the available water storage by releasing flows from the Ripogenus Project that were higher than the required minimum flows. And since water management is within GLHA's control, the complainants argue that the minimum flow reductions were not allowed by the Project license.

While noting that the complainants have the benefit of retrospectively criticizing GLHA's water management actions (as opposed to GLHA's need to implement water management actions in real time), GLHA's water management decisions at the Ripogenus Project during the recent severe drought conditions are fully justified and entirely in compliance with the Project license. For example, while GLHA has implemented water conservation measures during the recent severe drought conditions on the Upper Penobscot drainage (including the implementation of reduced West Branch spawning and incubation flows, and by routinely reducing Ripogenus flows during non-rafting hours), GLHA must also use water stored at the Ripogenus Project to maintain compliance with its downstream Penobscot Mills Project license (FERC No. 2458), which requires both relatively stable water levels at the North Twin impoundment (from May 1 to August 22 annually) and a minimum flow of 2,000 cfs at Millinocket. And since the Ripogenus impoundment becomes the primary source of water to satisfy these downstream license requirements during drought conditions (as tributary and natural inflows dwindle), GLHA commonly releases flows from the Ripogenus Project that are in excess of minimum flows during dry and low inflow conditions.

Fax: 207.723.3948

Brookfield Renewable

The 1991 Water Use Plan (WUP, or Plan) referenced by the complainants was developed to support the last relicensing of both the Ripogenus and Penobscot Mills Projects, and it recognized that the numerous benefits derived from the Plan at both Projects would be provided while "*the Ripogenus impoundment would continue to be drawn down*" (i.e., the water management requirements and benefits contained in the current FERC licenses for these Projects are largely dependent on Ripogenus impoundment water). As detailed in the Plan, the WUP resulted in "*a significant re-regulation of Great Northern's entire reservoir and hydro-generation system to meet, wherever possible, the resource use and management goals identified by agencies and private groups.*" The Commission utilized the WUP in its development of the 1996 FERC licenses for the Ripogenus and Penobscot Mills Projects, and thus, the WUP is the basis for the licensed water management requirements (which are intended to balance public safety, recreational, environmental, and power generation needs) under which GLHA currently operates both Projects.

GLHA notes that while the 1991 WUP was developed to serve as a comprehensive and long-term management plan for the storage system, the WUP also did not anticipate that the subsequent (2004) FERC license for the upstream Storage Project (FERC No. 2634) would result in a substantial loss of available storage capacity in the West Branch of the Penobscot River drainage due to the following drawdown limitations:

Canada Falls Lake (0.56 billion cubic feet [bcf] lost)
Seboomook Lake (2.68 bcf lost)
Penobscot Lake (0.06 bcf lost)
Dole Pond (0.16 bcf lost)
Loon Lake (0.46 bcf lost)
Harrington Lake (0.01 bcf lost)

Additional water storage on the West Branch has been lost since 1996 with the implementation of wetlands mitigation at Umbazooksus Lake (0.45 bcf lost) and the transfer of Nesowadnehunk Lake Dam to a stakeholder (0.42 bcf lost). All told, total storage capability on the West Branch has been reduced by nearly 5 billion cubic feet since the WUP was finalized in 1991, thereby hindering WUP-based water management in the West Branch drainage.

Finally, as part of its contractual obligations with ISO – New England, GLHA is required to perform a CCA (claimed capability audit) test each summer (and once every 3 years in the winter) by maximizing generation at its facilities for short periods of time. The 2021 CCA test was performed at the Ripogenus Project on August 12, 2021, which resulted in a flow of 3,300 cfs for several hours, well above the minimum flow.

Project operational data – as requested by the Commission's May 26, 2022 letter, a table is attached that provides hourly operational flow data for the Ripogenus Project both from October 15, 2021 through April 18, 2022, and also for the May 17th and 18th, 2022 time periods. As shown by this table, GLHA released flows from the Project which for all hours exceeded the licensed minimum flows, and/or the reduced minimum flows established through agency consultation due to hydrologic conditions that resulted from the severe drought in the upper Penobscot watershed.

Brookfield Renewable

In summary, the complaints filed by Mr. Heinz and Mr. Spear alleging noncompliance with Article 402 of the Ripogenus Project license are without merit, as GLHA's water management actions at the Ripogenus Project during the recent severe drought conditions are fully justified and entirely in compliance with the Project license.

JEFF KAINE, HERMON, ME.
Good afternoon,

My comment will be short and to the point. What is going on with crazy up and down flows on the West Branch of the Penobscot River. Those poor fish donâ€™t stand a chance with the crazy fluctuations. As bad as the fish have it, the insects and other life in the river are suffering tremendously!! Iâ€™ve seen sculpins and stoneflies get trapped because of the extreme drops in flows. They all end up dying because of it, which in turn is taking food out the mouths of the fish in the river. I have noticed a decline in the fishery in recent years and I blame the extreme up and down flows. When the flows were more consistent (years past), the fishery thrived and so did any businesses along the way to the River.
Please change your policies to help the fish, the rafters, the small fish and insects and of course the businesses.

Thank you for your time,
Jeff

Kimberly D. Bose, Secretary
Federal Energy Regulatory Commission
888 First Street, N.E.
Washington, D.C. 20426

**Subject: Penobscot Mills Project (FERC No. 2458); Millinocket and East Millinocket Developments; Flow and Water Level Modifications due to Flashboard Losses and Repairs**

Dear Secretary Bose:

Great Lakes Hydro America, LLC (GLHA) is reporting run-of-river (ROR) and water level modifications at the Penobscot Mills Project (Millinocket and East Millinocket Developments) for planned drawdowns to accommodate flashboard repairs. GLHA is the licensee for this Project, which is located on the West Branch of the Penobscot River in Maine.

**Penobscot Mills (FERC No. 2458)**

Article 403 of the Penobscot Mills license states in part that:

"*The licensee shall operate the Millinocket, Dolby, and East Millinocket developments in a run-of-river mode while providing an instantaneous minimum flow of 2,000 cubic feet per second (cfs) to the West Branch of the Penobscot River at Millinocket, for the protection of water quality and aquatic habitat in the Penobscot River. The licensee shall at all times act to minimize the fluctuation of the reservoir surface elevations by maintaining a discharge from each of these developments so that, at any point in time, flows, as measured immediately downstream from the tailraces of the developments, approximate the sum of the inflows to the project reservoir. Run-of-river operation or minimum flows may be temporarily modified if required by operating emergencies beyond the control of the licensee, and for short periods upon mutual agreement between the licensee, the U.S. Fish and Wildlife Service, and the Maine DEP. If the run-of-river operation or minimum flow is so modified, the licensee shall notify the Commission as soon as possible, but no later than 10 days after each such incident*."

**Millinocket Development ROR Flow Modification, May 27, 2022 – June 3, 2022**

Through agency consultation and as detailed below and in the attached graph, the Millinocket impoundment was drawn down from May 27, 2022 to June 3, 2022 for flashboard repairs. This event resulted in a modification in ROR operations at the Millinocket Development as follows:

Start of planned drawdown to repair flashboards: May 27, 2022
Minimum impoundment level: 455.48 feet USGS (3.22 feet below full pond)
Flashboard repairs: May 31, 2022
Impoundment refilled, and ROR operations resumed: June 3, 2022

**East Millinocket Development ROR Flow Modification, May 27, 2022 – June 3, 2022**

Through agency consultation and as detailed below and in the attached graph, the East Millinocket impoundment was drawn down from May 27, 2022 to June 3, 2022 for flashboard repairs. This event resulted in a modification in ROR operations at the East Millinocket Development as follows:

Start of planned drawdown to repair flashboards: May 27, 2022
Minimum impoundment level: 282.37 feet USGS (4.83 feet below full pond)
Flashboard repairs: June 1, 2022
Impoundment refilled, and ROR operations resumed: June 3, 2022

**Conclusion**

The Penobscot Mills Project license allows flows and water levels to be temporarily modified for short periods upon mutual agreement between GLHA, the Maine Department of Environmental Protection (MDEP), and the United States Fish and Wildlife Service (USFWS). On May 26 and May 27, 2022, GLHA notified these agencies, together with the Maine Department of Inland Fisheries and Wildlife (MDIFW), the Maine Department of Marine Resources (MDMR), the U.S. Bureau of Indian Affairs (BIA), the National Marine Fisheries Service (NMFS), and the Penobscot Indian Nation (PIN), of its plans to lower the impoundments to accommodate flashboard repairs. The agencies and PIN provided no comments nor objections regarding this modification of flows and water levels at the Millinocket and East Millinocket Developments.

GLHA is not aware of any adverse impacts to fish or wildlife resources or water quality in the West Branch of the Penobscot River as the result of these water level and ROR flow modifications, and no additional incidents (safety, dam safety, public safety, security) resulted from this event.

If you have any questions, please contact me by phone at (207) 951-5006 or by e-mail at kevin.bernier@brookfieldrenewable.com.

Sincerely,

Kevin Bernier

| **Subject:** | Upper Penobscot flashboard repair plans |
| **Date:** | Thursday, May 26, 2022 8:39:33 AM |
| **Attachments:** | image001.jpg |

Although elevated flows have persisted on the Upper Penobscot later than normal this year, they are now dropping, and we intend to replace flashboards at the Stone (Millinocket), Dolby, East Millinocket, Weldon (Mattaceunk), and West Enfield Dams over the next two weeks. Although I know we are entering bass spawning and loon nesting seasons, completing this work is a priority, and the sooner we can return to normal operations the better. Our current plan is to repair flashboards at Dolby tomorrow, May 27th, and then at Stone, East Millinocket, and Weldon dams next week. The West Enfield flashboard repairs are tentatively scheduled for the following week (week of June 6th). Each will require a drawdown (7.5 feet from full pond for West Enfield; 4.5 feet from full pond for Dolby, East Millinocket, and Weldon; 3 feet from full pond for the Millinocket impoundment), which would generally begin 2 – 5 days before the scheduled work in order to achieve a gradual drawdown. However, most of these impoundments have already begun to drop due to missing flashboards. I would also note that the upstream fishways at West Enfield and Weldon Dams will be temporarily dewatered during the drawdowns, which should have minimal effect on Atlantic salmon, as few if any are in the river upstream of Milford Dam (most salmon are collected at the Milford fish lift and trucked to the hatchery for broodstock). We are also making plans on how to manage upstream-migrating river herring at West Enfield as the fishway becomes dewatered.

Please let me know if you have any questions or concerns with this schedule, and I will update you if these plans change. Keep in mind that the impoundments are going to drop one way or another as river flows come down, whether we draw the impoundments down intentionally for repairs, or the ponds naturally drop due to the flows through the damaged and missing boards.

Please let me know if you have any questions, concerns, or comments regarding these drawdowns for flashboard maintenance.

| **Date:** | Friday, May 27, 2022 1:17:23 PM |
| **Attachments:** | image001.jpg |

In light of agency and tribal concerns and the fact that the West Enfield flashboards are in comparatively good condition and passably functioning, Brookfield will hold off on drawing the West Enfield impoundment down for flashboard repairs until sometime this summer. However, we will maintain our current plans for flashboard drawdowns at Dolby, Stone, East Millinocket, and Weldon Dams over the next week, starting with Dolby where flashboard repairs are being made today.

Jeff – in reply to your question, the upstream fishways at Weldon and at West Enfield are both substantially dewatered when the impoundments are lowered to the spillway crest elevations of each dam.

Thank you for your feedback, and please let me know if you have any additional questions, concerns, or comments regarding these drawdowns for flashboard maintenance.

**FERC Project 2458**
**Article 403**

Kimberly D. Bose, Secretary
Federal Energy Regulatory Commission
888 First Street, N.E.
Washington, DC 20426

***Electronically Filed***

**Subject: Penobscot Mills Project, FERC No. 2458; Article 403;**
**Status Update on Corrective Actions**

Dear Secretary Bose:

Great Lakes Hydro America, LLC (GLHA), licensee for the Penobscot Mills Project (Project), submits this letter in reply to Commission correspondence dated May 17, 2022, in which the Commission requests updates on several corrective actions noted by GLHA in flow excursion reports for the Project dated September 9, September 27, September 30, and November 12, 2021, and February 14, 2022. The corrective actions, together with GLHA's status updates on these actions, are provided below:

Develop a switching procedure for isolating the battery systems and provide training on the procedure – a switching procedure for isolating the battery systems has been developed, and crew training on the procedure is scheduled for July 2022.

Repair a damaged lighting arrestor at McKay Station (part of the Ripogenus Project, FERC No. 2572) – the lightning arrestor was repaired on September 9, 2021.

Repair the hydraulic governor controls on units #6 and #8 at Dolby Station – repairs to the hydraulic controls on unit #8 at Dolby were completed on February 22. 2022. GLHA's investigation of Dolby unit #6 determined that the unit has an exciter issue (rather than a governor issue); a new exciter for the unit is on order.

Resolve an issue with the unit #7 governor system at the Millinocket Development – repairs to the governor system for unit #7 at the Millinocket Development were completed on February 23, 2022.

Please e-mail me at kevin.bernier@brookfieldrenewable.com or call me at (207) 951-5006 if you have any questions or need additional information on these corrective actions.

Sincerely,

Kevin Bernier

Project No. 2572-136 : Ripogenus Project (P-2572) Comments On Great Lake Hydro America June 8, 2022 Response to FERC's, May 26, 2022 Request for Additional Information.

Great Lake Hydro America's (the Licensee) June 8, 2022 response is a continuation of legalese, repetition of licensing language, inclusion of irrelevant and erroneous data, and fails to address the major License issues, Article 406, raised in the May 9, 2022 and May 20, 2022 correspondence. In addition, whatever arrangement the Licensee has with ISO NE, it is subservient to its License to operate facility units at all and the environmental condition contained therein. If the Licensee believes otherwise, they should be made to prove it. If they cannot, FERC should call out this obfuscation. The following paragraphs outline the misrepresentations of facts and data related to environmental matters at hand.

Minimum Flow

While the March, 2022 emergency minimum flow of 800 cfs from McKay Station may meet 401 WQC guidelines, no end point was established. The default license requirements are that minimum flows meet the greater of predetermined flow standards or inflow. During April, inflow had increased and the impoundment was filling yet the emergency flow of 800 cfs was maintained. This and subsequent low flow events impacted salmonid spawning, incubation and juvenile salmon habitat needs as well as aquatic communities. The Licensee asserts that Article 402 conditions were met, however, Article 406 conditions were not met. The Holbrook Bypass Channel (Bypass) and well as downstream spawning and incubation areas were dewatered and salmonid and aquatic communities suffered. The violation of Article 406 is clear. Recently (May to early June 2022) the Licensee reduced McKay Station flows to 1300 cfs at 5 PM before increasing flow by 8 AM the next morning. The Bypass was not engineered to operate at a McKay Station flow of 1300 cfs, nor are salmon eggs able to abandon redds and recolonize as the channel ebbs and flows. I have seen no filing indicating the Licensee has made Bypass Chanel gate changes in an attempt to provide June 1st flow of 35 cfs to the Holbrook Bypass Channel, or if in fact, that the two pipes are capable of even providing the License requirement 35 cfs flow at 1300 cfs.

Storage Management

The Licensee states they were in full compliance of licensed flow requirements of Article 402. The issue that needs to be addressed is storage management as it relates to flow management. The Licensee argues that they were unaware of the need to conserve water while "the complainants have the benefit of retrospectively criticizing GLHA's water management". So, a company that operates the largest two storage systems in Maine states it cannot predict or monitor drainage system conditions. Really? They say this while noting "the recent severe drought conditions" and "severe drought conditions that have plagued the upper Penobscot River drainage since 2020…" Additionally, in a February 23,2022 letter (20220429-5127_2022), Mr. Kevin Bernier writes "*current and historic drought conditions in Maine, Great Lakes Hydro America, LLC (GLHA), licensee for the Storage (FERC No. 2634), Ripogenus (FERC No. 2572), and Penobscot Mills (FERC No. 2458) Projects, has been implementing water conservation measures on the Upper Penobscot since the current drought intensified beginning in 2020*". They are aware now but not then? It is left to one's imagination as how these

"conservation measures" were applied to license articles and environmental needs. The Licensee was fully aware of the need to conserve water in order to meet License requirements such as Article 406 and failed to do so.

The Preliminary Application Document (PAD) and Notice of Intent (NOI) boasts of Protection, Mitigation and Enhancement (PME) measures provided by project operations. During 2021 these measures were ignored by the Licensee. By June of 2021, inflows were low and the Ripogenus Impoundment level falling. The License has stated the Water Use Plan (Plan) does not meet current (peaking) flow objectives. However, the Licensee has now reinvented this plan and appear to use it as an excuse for its failure to meet License conditions. Had the Licensee followed the FERC approved Great North Paper's Rule Curve, or Water Use Plan or noted "local" weather forecasts, McKay Station flows could have been reduced and storage retained. Project operations are totally under the Licensee's control and the violation of Article 406 would have not occurred had the Licensee followed the FERC approved Rule Curve. The Licensee willfully used Ripogenus Impoundment Storage to meet peaking energy demands not contemplated when FERC issued the 1996 License. The Violation of Article 406 was avoidable and the responsibility lies with the Licensee. If FERC does not act, the Licensee will continue to ignore the environment. It has a strong profit motive to do so.

Water Conservation

The Licensee claim that they reduce flows following scheduled rafting releases as a water conservation measure. The boating flow requirement ends at 5PM but higher flows continue to 8 or 9 PM. It is impossible to see this action as water conservation and not peaking activity. It seems that the Licensee uses rafting/boating flows as an excuse to operate high flows during prime energy markets. This is a further contradiction as the PAD/NOI (5.3.4.1) states, regarding the West Branch, "stable year-round flows" are provided.

Facilities that fail to Provide Storage to the Ripogenus Impoundment

The "transfer of Nesowadnehunk Lake Dam to a stakeholder (0.42 bcf lost)" has nothing to do with Ripogenus Impoundment Storage shortcomings. Nesowadenhunk Stream is well downstream of McKay Station and the contribution of storage has nothing to do with the issues at hand, violations of Licensee articles and PME measures. Unless the Licensee is making a case for developing a peer-reviewed water management plan, including long abandoned small storage ponds is simply an attempt to redirect FERC's focus, a total red herring.

Upstream Storage: FERC Project No. 2634

The Licensee provides erroneous and misleading information in an attempt to obscure its failure to meet License conditions. These errors indicate a lack of understanding of 1) available water stored in the storage project 2) location of "storage ponds" that provide flows into the Ripogenus Important 3) the operation of the Storage Project i.e., "winter" drawdowns (gate settings). 4) the factual consideration of the WUP during the licensing of the Storage Project.

During the 1990s, consultants to Great Northern Paper (GNP) evaluated the contribution of water "stored" in the Storage Projects impoundments to overall mass inflow/storage. The Licensee should make this study available to FERC and the stakeholders. The study assumed that the storage Project impoundments were only of value when they "captured" or "stored" water that could not be stored in downriver locations. The GNP's consultant study of the Storage Project value found that average annual contribution was approximately 50% of storage ponds capacity. Simply, downstream capacity had to be "reached" before the Storage Project produced value. The 2021 water year demonstrates this point, the Ripogenus Impoundment never filled and

all storage Project inflow could have been captured in the Ripogenus Impoundment. As a result of the 1990s study of "upstream" storage, a number of facilities were considered *de minimus* in their storage contribution and/or not practical or cost effective. These facilities, "*Penobscot Lake (0.06 billion cubic feet [bcf]) Dole Pond (0.16 bcf), Loon Lake (0.46 bcf), Harrington Lake (0.01 bcf)"* were all scheduled for abandonment or to be turned over to third parties. As their total potential contribution is neglectable and they were originally scheduled for abandonment it is ridiculous to argue that they contributed to storage shortfalls.

More obfuscation, the Licensee claims it has lost 5 bcf as the result of Storage Project Licensing but the "numbers" don't add up. The Licensee states that 2.58 bcf of Seboomook Storage has been lost. This is simply untrue. As FERC is well aware of, "winter" gate setting protocols (normally around November 1st) are to open the facilities (deep) gates and drain all remaining storage. No storage is lost as any remaining water flows into the Ripogenus Impoundment. The Canada Falls facility (and all other facilities) operates in a similar manner and any remaining "ponded" water (Canada Falls .56 bcf) is released following winter gate setting.

The License noted in the Revised Study Plan (1-14) the "*1991 Water Use Plan is not a "management plan" consistent with other management plans, is not suited for its present management"* . In recent filings the Licensee has used the WUP as foundation for present operations. This is a contradictory, both cases can't be true. So is the WUP plan workable or archaic, a tool to be used in flow management or a prop only to be used when making legal arguments?

The Licensee, now eager to invoke the WUP, states that under the plan ""the Ripogenus impoundment would continue to be drawn down". This is correct but misrepresents the circumstances; the timing and degree of drawdown. The issues at hand are not drawdowns but the degree and timing of such events. Prior discussion of "Rule Curve" operations inherently involves drawdowns, winter drawdowns rather than July drawdowns. Thus, if the licensee is going to depend on the WUP in its defense, it should note that drawdowns under the WUP would occur in late fall and winter. This has not been the case in recent years.

The Licensee argues that the WUP was not considered in the licensing of the Storage Project. Again, this is simply incorrect. Is the Licensee suggesting that GNP was unaware that the Storage Project (P-2634) both existed and was soon to enter the licensing process? As with all other licensing events, I was present and an active participant. The Licensee's assertion is simply untrue and illogical. Storage was always GNP's major focus. GNP needed to make paper year-round. The Project License resulted in GNP maintaining much of its storage capabilities albeit, with staged drawdown. This resulted in a two-to-three-month delay in the storage arriving in the Ripogenus Impoundment and a slight loss, perhaps two feet, in McKay Station head. The delayed, slower drawdown(s) and increased minimum stream flows produced fisheries, aquatic community and angling benefits and well as boating flows.

<u>The Failure to Address Article 406 Violations</u>

Filings on May 9, 2022 and May 20, 2022 focused on the failure to provide licensed flow(s) into the Holbrook Bypass Channel (Bypass) and downstream spawning, incubation and nursey habitat. This was a clear violation of Article 406. The Licensee failed to address this concern. FERC should require the Licensee to acknowledge this, perhaps ongoing, violation and mitigate for their failure.

In summary, FERC should require the Licensee to address the violation of Article 406. FERC should also require the Licensee provide the "contractional obligation with ISO NE" it claims exist as well as the 1990s GNP evaluation of the Storage Project contribution to the West Branch/Ripogenus storage "operating budget". FERC should take action. The regulatory system cannot work without honesty and transparency. If I was not

investing my time, with my unique knowledge of historical West Branch events and facts on the ground, who would be identifying the shortcomings of the Licensee's filings?

Thank you for the opportunity to comment.

Ripogenus Project FERC No. 2572 FERC No. 2458

Kimberly D. Bose,
Secretary Federal Energy Regulatory Commission Penobscot Mills Project 888 First Street, N.E.
Washington, D.C. 20426

Subject: Ripogenus Project (FERC No. 2572); Penobscot Mills Project (FERC No. 2458); Minimum Flow Reductions Comments

Dear Ms. Rose,

I am writing in response to Kevin Bernier's June 8, 2022 letter regarding reduced minimum flow at the Ripogenus Project. Mr. Bernier blames the regional drought for the excessive drawdowns of 2021 which necessitated a reduced minimum flow at the project. The Operations Data provided by Brookfield indicates operations management compounded the impact of the drought.

Mr. Bernier claims whitewater requirements necessitated the releases of 2021. He states,

> "*Article 402 of the Ripogenus Project license requires that minimum whitewater recreation flows of between 1,800 and 2,300 cfs be released from the Project between 08:30 and 17:00 hrs on a daily basis between May 1st and September 15th."*

The requirements as written on the Safewaters website, are more nuanced, identifying variations for "dry" hydrologic years.

> *"Dry" hydrologic years - 2200 CFS on Saturday and Sunday; 2000 CFS on Monday and Friday; 1800 CFS Tuesday through Thursday."*

2021 was a dry hydrologic year. The attached chart, which I compiled from the Operational Data shared by Brookfield, shows daily flows throughout August of 2021 and the difference between required flow and actual flow. The chart clearly demonstrates that on 23 days more water was released than required by whitewater commitments. Twelve of these days were 842 to 2230 cfs more than required. Anecdotal data confirms many days the release went well beyond the 5:00 pm requirement, sometimes through the night. Hourly data, as requested by other agencies, would be necessary for further support.

Recognizing reducing flows during non-rafting hours would be beneficial during a severe drought, Mr. Bernier claims,

> *"GLHA has implemented water conservation measures during the recent severe drought conditions on the Upper Penobscot drainage …by routinely reducing Ripogenus flows during non-rafting hours)."*

As also shown in the attached chart, this claim is not supported by the Operational Data provided by Brookfield.

Mr. Bernier acknowledges one day of high flow as he explains Brookfield's commitment to ISO to perform a CCA test each summer,

*"The 2021 CCA test was performed at the Ripogenus Project on August 12, 2021, which resulted in a flow of 3,300 cfs for several hours, well above the minimum flow.*"

Operational Data shows a release of 3231 cfs on August 12th. It also shows releases above 3000 cfs on August 1st, 2nd, 3rd, 13th, 14th, 21st and 22nd as well. Some of these flows often lasted well beyond 5:00 pm. Again, hourly Operations Data is necessary to confirm duration of flows.

Mr. Bernier identifies downstream commitments as another reason for the dewatering of Chesuncook, Caribou and Ripogenus lakes in 2021 when he states,

*"GLHA must also use water stored at the Ripogenus Project to maintain compliance with its downstream Penobscot Mills Project license (FERC No. 2458), which requires both relatively stable water levels at the North Twin impoundment (from May 1 to August 22 annually) and a minimum flow of 2,000 cfs at Millinocket."*

If 2000 cfs is released out of North Twin, logic dictates 2000 cfs would also need to be released from Ripogenus to maintain North Twin Lake levels. Every day in August of 2021 releases from North Twin were over 2000 cfs, and more than 2000 cfs was released from Ripogenus dam all but five days.

The data provided by Brookfield, which was not available when I originally wrote in March, clearly indicates Operational Management compounded the impacts of the drought.

To analyze the impact of operations management on lake levels and energy generated, using data from the past 10 years supplied by Brookfield and FERC, I charted lake levels at the end of May, June, July and August, yearly MWH generated, average inflow at Ripogenus and hydrologic status of the given year. The following illustrates the impact of operations management.

| | May 31 lake | June 30 lake | July 31 lake | Aug 31 lake | MWH generated/avg inflow at Rip/hydrologic |
|---|---|---|---|---|---|
| 2015 | 936.33 | 936.8 | 933.48 | 931.28 | 221,914 2322. dry-avg |
| 2012 | 937.29 | 939.67 | 936.71 | 932.71 | 266,009 2377 dry-avg |
| 2020 | 939.49 | 936.07 | 931.54 | 926.71 | 242,794 2316 dry |

In all three years the average inflow at Ripogenus was very similar. However, the energy generated and impact on lake levels varied dramatically. For example, 266,009 MWH were generated in 2012, while only dropping the lake 4.58 feet. In contrast, 242,794 MWH were generated in 2020 but the lake level dropped 12.79 feet, rendering the lake 15 feet down. With only a 2.57% inflow difference, 8.73% more energy with less environmental impact was generated in 2012 than 2020. From this layperson's eyes this data seems to indicate operations management does make a difference.

Mr. Bernier states,

> *"GLHA's water management decisions at the Ripogenus Project during the recent severe drought conditions are fully justified and entirely in compliance with the Project license."*

Management decisions may comply with the license, but are they "fully justified?" The data does not indicate so. My purpose is not to chastise, or place blame. My purpose is to clarify and promote change. The devastation of 2020 and 2021 cannot happen again. It is not "fully justified." There are lessons to be learned from the 2020-2021 seasons. Lessons that can help meet the interests of all stakeholders, and provide a fair and balanced use of the water that does no harm.

Thank you for your time and consideration.

Sincerely,

Kathleen K. Houston

Sarah Sindo, MILLINOCKET, ME.
My name is Sarah Sindo and I am from Millinocket, ME. I am the site manager at Chewonki Big Eddy Campground, located on the West Branch of the Penobscot River. The property is about 2 miles downstream of Ripogenus Dam.
Last night, June 24, 2022, the river was scheduled to go from 3,000 cfs to 3,500 at 5pm. I read this on the SafeWaters website. Shortly after 5pm, a camper commented to me, “Wow, the river went way down!” I looked at and saw the gravel shore across the river. I came inside and checked the SafeWaters website again. The flow read 1,900 cfs.
This is one of the campground’s busiest fishing weekends of the season, and to have a 1,000+ cfs change in flow is very significant and detrimental to the fishing.
Secondly, according to the SafeWaters website, a flow of 1,900 cfs is outside of their annual release schedule. I am not sure if we are in a “normal” or “wet” hydrologic year, but with Ripogenus Lake being full, I might imagine it’s considered a “wet” year. If it is, the minimum flow on a Friday should be 2,000 cfs.
Annual Release Schedule

May 1 - September 15 between the hours of 0830 and 1700
"Normal" hydrologic year - 2300 CFS on Saturday and Sunday; 2200 CFS on Monday and Friday; 2000 CFS Tuesday through Thursday
"Wet" or "Dry" hydrologic years - 2200 CFS on Saturday and Sunday; 2000 CFS on Monday and Friday; 1800 CFS Tuesday through Thursday

We have seen fluctuating flows this spring and it has surely influenced the less than productive fishing and bug hatches.
Thank you for the opportunity to submit a comment, and I appreciate you taking the time to read my comment.
Thank you.

Julie A Puleio, BRUNSWICK, ME.
My name is Julie Puleio. I work for the Chewonki Foundation at the Big Eddy Campground campus on the West Branch of the Penobscot River.

On the Evening of Friday June 24th at 1615 Eastern Standard time the flow of the river dropped to 1921cfs. The schedule flow was due to rise to 3500cfs as of 1600EST from the daytime flow of 3000cfs. This drop in the river was greater then 1000cfs in a rapid period of time was alarming to me as I was preparing to go surfing at the high water level and quickly changed my plan not to.

Over the years we have witnessed several of these unscheduled sudden drastic drops in water flow on this river. These events impact the fishing and recreational activities and those participating. When you prepare for 3500cfs and arrive to find 1921cfs it changes everything about the way you can acsess and utilize the river from a fishing and whitewater perspective.

These dramatic fluctuations also effect the most venerable on the river, the many species of aquatic invertebrates that require the water in the river in order to live. It has been my observations over the years that these sudden drops in the river flow leave many different insects stranded on the rocks of the Big Eddy Shore.

I have photographs of the flow schedule and drop of river flow if there is an opportunity to submit I would.

Thank you for the opportunity to comment.

Paul Heinze, Bowerbank, ME.
I have been fishing the West Branch of the Penobscot for over 20 years. I have witnessed the steady deterioration of fishing quality in that time. The insect life was once prolific and the fish were strong and healthy. Over the years, the river level seems to be allowed to fluctuate more and more dramatically (high during peak demand â€“ i.e. daytime flowsâ€¦ and lower at night). The once prolific clouds of caddis hatches that used to cover my truck after a trip up the golden road are no longer. On a recent evening trip the water level was at 900. Yes, 900. This was confirmed by several folks around the Big Eddy campground who monitor for violations. The caddis flies were few and far between. Hardly any. The healthy adult salmon that were once so common on this river are now, likewise, few and far between. I believe that the caddis are critical to the ecosystem of this river and that the extreme river level fluctuations are having a very detrimental effect on the health of the caddis fly population and therefore on the health of the salmon themselves and of the salmon population. I hope that as part of relicensing a study on the impact of river fluctuation on the caddis fly (and other insect) abundance will be taken and considered.

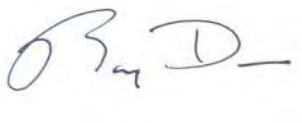
**Subject:** **Ripogenus Hydroelectric Project (FERC No. 2572-133)**
**Penobscot Mills Hydroelectric Project (FERC No. 2458-247)**
**First Study Progress Report**

Dear Secretary Bose:

Great Lakes Hydro America, LLC (GLHA), Licensee of the Ripogenus Hydroelectric Project (FERC No. 2572) and the Penobscot Mills Hydroelectric Project (FERC No. 2458) (collectively referred to as the "Projects"), herein files with the Federal Energy Regulatory Commission ("FERC" or "Commission") the First Study Progress Report for the relicensing of the Projects. The Projects are located on the West Branch of the Penobscot River and Millinocket Stream in Piscataquis and Penobscot Counties, Maine.

The current licenses for the Projects were issued on October 22, 1996 and expire on September 30, 2026. On June 11, 2021, GLHA filed the Notices of Intent and Pre-Application Document (PAD), which initiated the formal relicensing proceeding to obtain two separate new licenses for the continued operation of the Projects through the Commission's Integrated Licensing Process (ILP). On March 23, 2022, GLHA filed a Revised Study Plan (RSP) for the Projects and the Commission issued the Study Plan Determination (SPD) on May 13, 2022.



Pursuant to the RSP, GLHA herein submits the First Study Progress Report for the period from May 1, 2022 through July 31, 2022 for the Projects. The enclosed table (report) provides a list of the required studies and associated status of progress as well as any modifications to the approved methodologies.

Concurrent with this filing, GLHA is providing a copy of this letter to all parties listed in the attached distribution list. A copy of the First Study Progress Report can be downloaded from FERC's eLibrary system at https://www.ferc.gov/docs-filing/elibrary.asp by conducting a search using the docket numbers p-2458 and/or p-2572.

| Ripogenus Hydroelectric Project (FERC No. 2572)<br>Penobscot Mills Hydroelectric Project (FERC No. 2458)<br>First Study Progress Report<br>(May 1, 2022 through July 31, 2022) | | | |
|---|---|---|---|
| **No.** | **Study** | **Status** | **Modifications to Methodology** |
| 1a | Water Quality Study – Impoundment Lake Trophic Assessment | Pursuant to the RSP and SPD:<br>• Impoundment water quality monitoring locations were established in late May 2022 and locations were communicated to MDEP.<br>• Routine biweekly sampling events are being performed.<br>• Data collected in 2022 will be provided in the ISR. | None. |
| 1b | Water Quality Study – Downstream DO/Water Temperature Assessment | Pursuant to the RSP and SPD:<br>• Riverine water quality monitoring locations were established in late June 2022.<br>• Routine weekly sampling events are being performed.<br>• Data collected in 2022 will be provided in the ISR. | None. |
| 1c | Water Quality – Benthic Macroinvertebrate Assessment | Pursuant to the RSP and SPD:<br>• Benthic macroinvertebrate sampling is anticipated to be performed in summer 2022.<br>• Proposed sample locations have been communicated to MDEP.<br>• Data collected in 2022 will be provided in the ISR. | None. |
| 1d | Water Quality – Impoundment Aquatic Habitat Assessment | Consistent with the RSP and SPD, the study is anticipated to be completed in 2022-2023 with data provided in the ISR. | None. |
| 1e | Water Quality – Riverine Aquatic Habitat Assessment | Consistent with the RSP and SPD, the study is anticipated to be completed in 2022-2023 with data provided in the ISR. | None. |
| 2 | Instream Flow and Habitat Assessment of West Branch below Stone Dam | Consistent with the RSP and SPD, the study is anticipated to be completed in 2022-2023 with data provided in the ISR. | None. |
| 3 | Fish Assemblage Survey Study | As required by the SPD:<br>• GLHA is developing a Fish Assemblage Survey Study Plan in consultation with the applicable resource agencies.<br>• GLHA anticipates performing the summer and fall surveys in 2022 with data provided in the ISR. | • GLHA has not yet completed consultation on the draft plan but is proposing a modified approach to sampling the Upper Gorge to reflect safety concerns. |
| 4 | Fish Stranding Study | As required by the SPD:<br>• GLHA is developing a Fish Stranding Study Plan in consultation with the applicable stakeholders. | None. |

| Ripogenus Hydroelectric Project (FERC No. 2572)<br>Penobscot Mills Hydroelectric Project (FERC No. 2458)<br>First Study Progress Report<br>(May 1, 2022 through July 31, 2022) | | | |
|---|---|---|---|
| **No.** | **Study** | **Status** | **Modifications to Methodology** |
| | | • GLHA anticipates performing the survey in mid-September 2022 (after the whitewater boating release season) with data provided in the ISR. | |
| 5 | North Twin Impoundment Tributary Access Survey | Pursuant to the RSP and SPD:<br>• GLHA developed a list of tributaries to be surveyed in consultation with MDIFW.<br>• GLHA anticipates completion of the tributary surveys in the summer and fall 2022 with data provided in the ISR. | None. |
| 6 | Upstream American Eel Passage Assessment Study | Pursuant to the RSP and SPD:<br>• GLHA initiated weekly nighttime eel observations at East Millinocket Dam in early June 2022.<br>• GLHA deployed two eel ramp traps at the toe of the East Millinocket Dam in late June 2022, which have been operational/checked weekly.<br>• GLHA initiated monthly nighttime eel electrofishing events in June 2022. Additional electrofishing events are planned for later this summer and into the fall.<br>• GLHA collected eDNA samples from the East Branch, West Branch, and mainstem Penobscot Rivers (with sample locations per the SPD communicated to the applicable resource agencies) in late July 2022.<br>• Data collected in 2022 will be provided in the ISR. | • Nighttime eel observations could not be performed in May 2022 due to spill conditions at the East Millinocket Dam.<br>• A nighttime eel electrofishing event could not safely be performed in May 2022 based on spill conditions at East Millinocket Dam and the lack of a boat barrier installed upstream of the Medway Dam. |
| 7 | Desktop Downstream Eel Passage Route and Survival Study | Consistent with the RSP and SPD, the study is anticipated to be completed in 2022-2023 with data provided in the ISR. | None. |
| 8 | Recreation Study | Pursuant to the RSP and SPD:<br>• GLHA installed survey boxes (and established an electronic survey) at the FERC-approved Project recreation sites as well as two additional locations that are used to access the remote campsites on Ripogenus impoundment in early May 2022.<br>• Since May 2022, GLHA has performed twice monthly recreation spot counts and calibration counts at the Project recreation sites. | None. |

| Ripogenus Hydroelectric Project (FERC No. 2572)<br>Penobscot Mills Hydroelectric Project (FERC No. 2458)<br>First Study Progress Report<br>(May 1, 2022 through July 31, 2022) | | | |
|---|---|---|---|
| **No.** | **Study** | **Status** | **Modifications to Methodology** |
| | | • GLHA anticipates completion of the recreation site inventory in the summer of 2022.<br>• Data collected in 2022-2023 will be provided in the ISR. | |
| 9 | Whitewater Boating Assessment Study | Pursuant to the RSP and SPD:<br>• GLHA installed whitewater interview sign-up card boxes at several whitewater put-in and take-out locations at the Projects.<br>• GLHA is interviewing whitewater boaters and interviews will continue into the fall 2022.<br>• Data collected in 2022-2023 will be provided in the ISR. | None. |
| 10 | Aesthetic Study | Pursuant to the RSP and SPD:<br>• GLHA established KOPs and initiated photo-documentation of views from each KOP in late June 2022.<br>• Data collected in 2022-2023 will be provided in the ISR. | None. |
| 11 | Historic Architectural Survey | Consistent with the RSP and SPD, the study is anticipated to be completed in 2022-2023 with data provided in the ISR. | None. |
| 12 | Historical Operations Data Assessment Study | Consistent with the RSP and SPD, the study is anticipated to be completed in 2022-2023 with data provided in the ISR. | None. |
| 13 | Operations Model Study | Consistent with the RSP and SPD:<br>• GLHA is in the process of developing and calibrating the operations model.<br>• GLHA anticipates consultation with interested stakeholders to discuss the model input data and calibration in 2022 or early 2023.<br>• The model input data and calibration data will be provided in the ISR. | None. |
| 14 | Wood Turtle Habitat and Presence Evaluation Study | Consistent with the RSP and SPD:<br>• The study will be initiated in 2022 in consultation with the MDIFW.<br>• Data collected in 2022-2023 will be provided in the ISR. | None. |
| 15 | Marsh Bird Survey Study | Consistent with the RSP and SPD:<br>• The study will be initiated in 2022 in consultation with the MDIFW.<br>• Data collected in 2022-2023 will be provided in the ISR. | None. |

| Ripogenus Hydroelectric Project (FERC No. 2572)<br>Penobscot Mills Hydroelectric Project (FERC No. 2458)<br>First Study Progress Report<br>(May 1, 2022 through July 31, 2022) | | | |
|---|---|---|---|
| **No.** | **Study** | **Status** | **Modifications to Methodology** |
| | | • If deemed necessary, field surveys will be performed between May 15 and June 30, 2023 with data provided in the USR filed with FERC in May 2024. | |
| 16 | Furbearer Survey Study | Consistent with the RSP and SPD, the study is anticipated to be completed in 2022-2023 (in consultation with MDIFW) with data provided in the ISR. | None. |
| 17 | Common Loon Management Plan Assessment Study | Consistent with the RSP and SPD, the study is anticipated to be completed in 2022-2023 with data provided in the ISR. | None. |
| 18 | Riparian and Littoral Habitat Assessment Study | Consistent with the RSP and SPD, the study is anticipated to be completed in 2022-2023 with data provided in the ISR. | None. |
| 19 | Terrestrial, Botanical and Wildlife Resources Study | Consistent with the RSP and SPD, the study is anticipated to be completed in 2022-2023 with data provided in the ISR. | None. |
| 20 | Environmental Justice Study | Consistent with the RSP and SPD, the study is anticipated to be completed in 2022-2023 with data provided in the ISR. | None. |

Project No. 2572-136 : Ripogenus Project, Comments On Great Lake Hydro America's September 15, 2022 Draft Fish Stranding Study Plans.

The proposed stranding study is intended to meet a Trout Unlimited (TU) concern with salmonid and macroinvertebrate stranding during emergency McKay Station (McKay) outages in the West Branch of the Penobscot River (West Branch). On February 21, 2022 TU filed the study request. TU's concerns are based on angler and boater's observations of salmonids and macro invertebrates stranded during emergency McKay outages. While strandings were only observed during the recreational season, May through October, McKay Station outages have been documented over the course of a year.

I am including addition historic information on sudden shutdowns of McKay Station. During the 1960s and 1970s I fished the West Branch downstream of McKay. At that time Great Northern Paper had a labor contract that required three day holidays (July 4th, Labor Day) and the Mill's paper production paused. Hydro power was not needed and McKay Station generation ceased. Base flows, typical around 2500 cfs abruptly stopped, and flow into the West Branch was though the Rip Dam deep gate, typical around 400 cfs. The sudden unramped flow resulted in stranded aquatic insects, dead or moribund aquatic insects were abundant in small pools, ledge, crevices, and rocky outcroppings. Insect (survivors) drift increased and the fish fed heavily and the fishing was spectacular (and is recorded in creel survey data collected by MeDIFW's Paul Johnson). It is likely that emergency McKay shut downs produce similar increase aquatic insect drift and stranding. Drift nets,

possibly located at Holbrook Pool, set and tended before, during and after outage flow would enhance the proposed stranding study.

Having reviewed Great Lake Hydro America's (the Licensee) September 15, 2022 draft study plans, I find the plan totally inadequate. As presented, the proposed study lacks insight into 1) fish behavior, 2) biological information contained in the 1992 FERC Application 3) hydrology, 4) study goals and 5) any possible successful outcome for useful information as the study is presently presented. I suggest that any fish stranding study be postponed until both biological and sampling conditions and protocols can be defined.

Fish Behavior; While all fish and macro invertebrate species and life stages have some vulnerability to stranding, it is the younger and smaller salmonid life stages and all macroinvertebrates that are most vulnerable to project operations. The Licensee's draft study fails to quantify let alone account for peak (seasonal) salmonid and macro invertrabrate vulnerability. A study conducted in October as fish and aquatic communities seek "winter" shelter fails to address behavior/habitat selection during the "spring-summer" growing season.

Juvenile salmon, namely fry, are most vulnerable during their first months of life, as they grow during the summer, they seek deeper areas with higher water velocities. More importantly, as water temperatures cool, typically below 50 f (10 c) they seek refuge in the interstices formed by large gravels and rocks and become more nocturnal. Heggenes (1990), Fraser et al. 1993, Gibson (1978), Heggenes, and Dokk,, (2001), reported behavior changes as water temperatures declined while Saltveit, et al. (2001) studied the salmon parr vulnerability to stranding as water temperatures dropped and behavior changed in a regulated stream and reported an increased winter mortality. Heggenes et al (2006) reported behavioral and habitat selection in response to

water temperature changes in a stream with “young salmon” and brown trout.

Biological Information; The 1992 License Application documents Landlocked salmon (salmon) habitat by life stages and river section(s). These data were based on electrofishing and angler surveys. Licensee has stated that these data are valid, no new information is needed. Yet the Licensee apparently has not reviewed the 1992 Application as it has proposed study locations NOT supported by 10-12 years of West Branch fisheries field work. The study plans (Methods 5) states the sampling areas will be areas “which are accessible, heavily fished, and known to provide habitat for cold water salmonids”. While the Big Eddy was once famous, the Licensee should provide current information to demonstrate current angler activity and presence of target species and life stages in the Telos Bridge and Nesowadnehunk Deadwater reaches. Collectively the three study sites presented in the draft plan make no sense as they sample areas where young-of-the-year salmon are known not to exist. Locations that should be sampled are areas that are known to contain habitat suitable for YOY salmon and (to a lesser degree) parr, macroinvertebrates AND where these habitats are vulnerable to outage flows. The idea that Nesowadnehunk Deadwater contains fry and parr habitat is absurd. The proposal to evaluated the Big Eddy is less far-fetched as parr are found in the high velocity area at the head of the pool and the shallower lower end of the pool. As with Nesowadenhunk Deadwater, the moderately deep Big Eddy is NOT Representative of areas where juvenile salmonids and riffle/run macro invertrabrates are present and subject to dewatering. (The Big Eddy contains some aquatic insect species

that prefer deeper/slower flows as well as receiving upstream insect drift). The Telos Bridge area has been subject to unnatural modification (log driving) and is high velocity featuring ledge and boulder substrates. This reach lacks velocity/depth/substrates that support YOY salmon production.

The February 21, 2022 TU filing states " impacts of "*generator outage flow*" on aquatic organisms." At this time, macro invertrabrates are strangely omitted from the study plan. Should macro invertrabrates be included, none of the proposed study reaches provide riffle/run areas that would be considered classic macroinvertebrate production areas for the species of Ephemeroptera, Plecoptera, Trichoptera that favor these habitats in the West Branch. Presentive areas include Holbrook Pool, the Horserace, and several side channels.

Hydrology: The Licensee fails to mention or perhaps understand West Branch flow dynamics. During an outage, flow drops over time and distance. However, the starting point flow (the McKay flow at the time of outage) is unknown for historical outages or for the proposed study. The drop in water surface elevation at various river reaches will depend on the base flow, channel configuration and travel time. Thus, several outage events, each with different initial base flow e.g. 2000 cfs, 2500 cfs, 3000 cfs, etc. are needed to demonstrate the degree of stranding.

The Holbrook bypass channel (Article 406) is a major component of mitigation measures required by the 1996 license. The goal of watering a dewatered side channel was the production of juvenile salmon. This was accomplished by creating a spawning, incubation, and nursey habitat by providing suitable flows. Flow is provided by two gates that are hydraulically controlled by the water surface elevation at Holbrook Pool. As flow into the bypass channel is a product of river flow and elevation, the relatively shallow bypass is extremely sensitive to any flow changes. Outage flows have to

potential to eliminate several salmon year classes and requires study. This oversight must be corrected.

Study goals: The draft study plan fails to mention macro invertebrates. These guilds, mayflies, stoneflies, caddis flies, crayfish, leeches, etc. provide the critical food source for juvenile and sub adult salmonids and a summer maintenance diet of adult salmon. These guilds are less mobile, thus more vulnerable to outages and stranding. This oversight needs to be corrected.

Study Results: As proposed, the draft study plan will produce little useful information. Even with the use of drones, searching for stranding in a large pool and a deadwater known for their lack of YOY salmon and few parr during a time period (October) when these life stages may have “retreated” into winter habitat is largely meaningless. If there are few or no target fish then the results are a forgone conclusion; no stranding!!!

The failure to include macro invertrabrates and the Holbrook Bypass Channel is a mystery. These two omissions fail to meet TU’s very reasonable February 15, 2022 request. The proposed study sites are not presentative of river reaches where significant stranding could occur.

I urge the Licensee to rethink the study and reschedule the “fish stranding study” for a period e.g., July, when juvenile salmonids and macro invertrabrates would be most vulnerable to stranding. The present study plans will not meet TU well thought-out goals.

Thank you for the opportunity to comment.

Todd Mercer, Poland, ME.
I have worked both as a raft guide and a fishing guide for the past 26 years on the west branch of the Penobscot River. I have watched as the water management practices have changed in the last couple of years, and I wanted to take a moment to explain my concerns. Understand Rip Dam is due for relicensing and this is our opportunity to comment regarding Brookfields practices and management of the watershed.

For many years the W.B. Penobscot water was managed with the health of the wildlife in mind. Water levels were stable, day and night for long periods of time. This allowed insects, fish, loons, eagles and osprey to flourish within the region.

I understand that once upon a time, the power ran the mill in town, so power 24 hours a day made sense. Now that Brookfield is selling power back to the grid, things are changing for the benefit of the company. During the last two seasons Brookfield has begun to manage the water levels much more like the Kennebec River. Running water during the day when prices are advantageous, and dropping water levels at night, when prices are low. Thus conserving the money making resource for peak pricing. This makes perfect sense to anyone who is thinking about how to to make money off the facility.

Unfortunately, the W.B. Penobscot is not like the Kennebec River. The Kennebec is a deep, high volume river which runs through a narrow gorge. The W.B. Penobscot, is a shallow river with some fast rapids, with long slower pools in between. When Brookfield drops the water from 2500cfs during the day, to 1400cfs in the evening, they are exposing the bottom of the river (10 to 20 feet of beach front at Big Eddy) where the larva and pupa stages of the insect life, they support and feed the fish within the river system, are living. We have seen a noticeable decline on the number of caddis available along the river over the past couple of years. If we continue to slaughter our insect life each evening, there will not be enough feed for the fish.

Of greater concern, are nesting loons. Each year there is at least one pair of nesting loons on the Nesowednehunk Deadwater. There is another pair on the Abol dead water. I cannot say for certain, but there is likely other pairings between Big Poc and Ambajejus. When the water drops, this also impacts Compass Pond and River Pond.

These wild swings in water levels leave loon nest stranded a long ways from the water. As most people know, loons are not adept at walking on land, and quickly abandon a nest they cannot get to them.

I recently learned of a study Brookfield is conducting on October 5, where they will drop the river to 400cfs to see observe the impact, and possibility of fish strandings. Right across from McKay station, there is a pool that will trap a large number of fish. I have not counted them when I have seen the water down, but I'm not talking about 5-10, it's more like 50-100.

If Brookfield is allowed to drop the river the 400cfs each night, it will decimate the river ecology.

I am asking that, as a condition of the renewed license, Brookfield be required to maintain the traditional consistent water level practices, rather than dropping the water at night. For the health of the entire eco system, including protected species like the Common Loon and the Balk Eagle, the water level is of vital importance.

Thank You for your time and consideration,

Todd Mercer
Poland, ME

Jeffrey Scott Murphy, Orono, ME.
On September 22, 2022, Great Lakes Hydro America, LLC (GLHA) provided a draft fish stranding survey study plan for review and comment. The stranding study was required by the Commission in the May 13, 2022 Study Plan Determination for the Ripogenus Project. The study was required to "provide a mechanism to evaluate the potential for, and magnitude of, fish and invertebrate stranding during generator shutdowns." The results of the study "could inform the development of license requirements for emergency minimum flows and the rate at which downstream flows are increased or decreased, if necessary [section 5.9(b)(5)]." While the Applicant was not required by the Commission to consult with the National Marine Fisheries Service in the development of this plan, we offer the following comments for your consideration.

As currently written, the proposed study plan will not achieve the objectives of the Commission's study plan determination. First, the proposed study ignores all areas of riffle, run, and braided channel habitat in the West Branch of the Penobscot River from McKay Station downstream to Nesowadnehunk Falls that will be most impacted by generator shutdowns at McKay Station. The Applicant proposes to survey two large pools (Big Eddy and Nesowadnehunk Pool) and below the Telos Bridge which they fully understand will be less affected by generator shutdowns. Second, the proposed study will not provide any data concerning the effects of generator shutdowns on non-mobile and limited-mobile lifestages of fish (eggs and fry) or any data on stranded macroinvertebrates at all. The Applicant proposes to conduct the study in October, 2022 when these lifestages of fish are absent in the West Branch of the Penobscot River. Lastly, the Applicant does not propose to collect any data on macroinvertebrates insects or mussels.

In summary, the draft study plan is wholly inadequate to meet the goals of the Commission's study plan determination and requires significant revision and stakeholder engagement to formulate a suitable plan.

Thank you, Jeff Murphy. National Marine Fisheries Service. Maine Field Station.

**Via online submission to: http://www/ferc.gov**

Subject: **Comments of Maine Council of Trout Unlimited on the Draft Fish Stranding Study Plan**

Dear Secretary Bose:

On behalf of its six chapters and over 2,000 members, Maine Council of Trout Unlimited (TU) submits these comments as a matter of record regarding the Draft Fish Stranding Study Plan (Plan) for the Ripogenus Project (P-2572) submitted late on September 13, 2022, announcing that the study would be conducted on October 5 and that comments were due "at your earliest convenience or by September 27, 2022."[1] This was in response to the FERC Study Plan Determination (SPD) that had been issued back on May 13, 2022. TU appreciates the opportunity to comment. We have included the Plan for FERC Staff convenience as Attachment A.

In the SPD, FERC Staff stated:

"Rapid changes in flow and decreases in water surface elevation can increase the risk of fish and invertebrate stranding which may be stressful and/or lethal for aquatic organisms."[2]

The SPD went on to say:

"The potential effects of reduced flows and flow fluctuations are likely to extend, at a minimum, to the nearest large, downstream pool. Therefore, we recommend GLHA conduct the Fish Stranding Study requested by Maine TU, through the area from McKay Station downstream to Nesowadnehunk Falls."[3]

It has been shown that fish and macro-invertebrate strandings occur during generator trip events. TU documented this during the August-September timeframe of 2021 when strandings were photographically documented.[4] The Brookfield Plan will not meet the study goal: "to determine the extent and degree of danger stranding pools that occur from below the McKay Station discharge to Nesowadnehunk Falls, especially under 400 cfs generator trip events" as stated in TU's formal FERC Study Request[5] provided as Attachment B. The Plan will not inform the relicensing process, and in its

[5] SPD, page B-4 and subsequent.

present form, the Plan has the potential to misinform the relicensing process by generating erroneous and inadequate study results by attempting to locate stranded fish in areas where they are unlikely to be stranded using methods that will likely fail to locate stranded fish.

**Plan Deficiencies**

Study Areas

The most significant deficiency is the plan's selection of study areas. Two of the three areas indicated the Big Eddy and Nesowadnehunk Deadwater[6] are deep pools where it highly unlikely strandings will occur. As written, the plan is likely to return data indicating that stranding is not occurring, or is not occurring in significant enough numbers of occasions to warrant concern.

While the Plan covers the area by Telos Bridge where TU documented the stranding in 2021, it does not include the area of greatest fisheries interest, the Holbrook bypass spawning and rearing area, or the area with the greatest stranding potential Big Ambejackmockamus Falls. As quoted above, the study was to include areas of stranding possibility between McKay Station and Nesowadnehunk Falls, TU sees no benefit to looking for stranded fish in deep pools where there is minimal stranding potential, TU does not see stranding potential in the Little Eddy, Nesowadnehunk Deadwater, or upstream in the gorge above McKay Station. The remaining waters should be covered including the small side-channels on the south bank below Little Ambejackmockamus Falls. If conducted as stated in the Plan, while there is inadequate information to compute a precise percentage, an eyeball estimate is that the study would devote over 95% of its effort to areas not expected to contain stranded fish. Besides the area below Telos Bridge where the stranding was photographed, north bank just below Telos Bridge, the side channel of the island immediately downstream should also receive special attention. Attachment C map is provided to show the study areas.

Brookfield states that TU indicates in recent letters that strandings occur in large pools during trip events.[7] TU is unaware of making such a statement and Brookfield does not include a citation.

Documentation/Data Collection

Nearly equally deficient in Brookfield's plan is the use of drones and boats to find trapped fish.[8] Fish are extremely difficult to spot in Maine's tannin-stained waters, even when wading. The photo series provided when documenting the fish stranding in 2021[9] makes this very clear and is provided as Attachment D. The study can only be conducted using 'boots on the ground.' It should be recognized that boats may be of some use in transporting field crews to the heads or tails of pools, or getting field crews to the north bank south of the Big Eddy.

[6] Draft Stranding Study Plan, page 3, Figure 1.
[7] Id., page 2.
[8] Id., page 4.
[9] TU Letter dated January 5, 2022, Subject: Maine Council of Trout Unlimited Amplifying Report for Observed Low Flow Events for the Ripogenus Project (P-2572), pages 3 through 5.

Rough examination of the productive study areas described above shows the distance from the tail of the Little Eddy to the head of the Big Eddy to be less than a mile, the Holbrook side channel less than a quarter of a mile, the island backchannel, a quarter of a mile, small side-channels on the south bank below Little Ambejackmockamus Falls less than a quarter of a mile, and from the tail of the Big Eddy to the head of the Nesowadnehunk Deadwater a little less than 3.5 miles – this totals to about 5 river miles more or less. At least a 20-member field crew would be required to cover both sides of a half mile stretch of river during a during a nominal 2-hour trip event given the large amount of dewatered area and the rocky, slippery conditions that will prevail. It will be important for the members of the field crew to document what areas they actually covered during the outage period to determine the magnitude of the strandings. Should a shorter outage period be used, a larger field crew would be required.

Duration of the Trip Event

The Plan states regarding duration: "The simulation event will be modeled after a "typical" station trip event identified from the 5-year operational data review (2018 – 2022)."[10] This time period was not specified in the draft plan and is an important omission. Minimum time to bring a crew in from Millinocket to effect restoral of previous flow levels is over an hour even under the new protocols. Accordingly, the duration of the event should be no less than two hours. Though also unspecified, we assume that the flows prior to the trip event would be the average summer daytime flows of 2200 cfs.

Macro-invertebrates

The TU formal FERC Study Request for Fish Stranding evaluation did not provide for documentation of stranded macro-invertebrates that are expected to be present in significant numbers. These were reported in the same filing as the fish stranding in 2021.[11] FERC recognized the importance of macro-invertebrates in its SPD.[12] Documenting macro-invertebrates during the course of the stranding study would be an excellent opportunity to assess project potential for the stranding of macroinvertebrate. Therefore, we ask that the Plan include data collection on stranded macroinvertebrates as well.

**Additional Information**

The stranding study should not be conducted in the fall after October 14 to avoid affecting salmonid spawning activities. This is consistent with project minimum flow requirements.[13]

[12] SPD, page B-5: "Accompanying field surveys, developed in consultation with Maine TU and Maine DIFW, would provide a mechanism to evaluate the potential for, and magnitude of, fish and invertebrate stranding during generator shutdowns. Collectively, these results could inform the development of license requirements for emergency minimum flows and the rate at which downstream flows are increased or decreased, if necessary [section 5.9(b)(5)]."
[13] PAD, page 4-45, Table4.4-1.

"Pursuant to section 5.15(c)(1) of the Commission's regulations, the initial study report for all studies in the approved study plan must be filed by May 13, 2023."[14]

**Point of Clarification**

The Plan shows the event commencing at 9:30 on October 5, 2022. We ask that Brookfield confirm that this is the time that the trip event will be initiated reducing the flow from McKay Station to 400 cfs and not just a reference schedule time. If TU is able to obtain volunteer observers for the event on October 5 on short notice, should it not be conducted, TU would like to be able to inform those volunteers and avoid unnecessary travel to the site. If Brookfield is unable or uncertain as to its ability to field the resources required to conduct the event, then Brookfield should announce that no later than 9:30 on Saturday, October 1. TU has expedited its review of the Plan as requested by Brookfield. We ask that Brookfield reciprocate the courtesy should the event not occur as specified in the Plan.

**Other Stakeholder Comments**

TU appreciates the email comment of MDIFW supporting inclusion of the Holbrook side channel in the study.[15]

**Conclusion**

Unless the measures contained in these comments regarding study areas, documentation/data collection and duration of the trip event are implemented by the stranding study, Brookfield will have failed to comply with the FERC Study Plan Determination.

Respectfully,

Stephen G. Heinz
Maine TU Council FERC Coordinator

**Draft Fish Stranding Study Plan – Ripogenus Project**

## 1.0 Requested Studies

In their Study Plan Determination (SPD)[1] for the Ripogenus Project, the Federal Energy Regulatory Commission (FERC) recommended that Great Lakes Hydro America, LLC (GLHA) study the existing emergency outage flow protocol during a station trip to assess whether it results in fish becoming stranded in pool habitat between McKay Station and Nesowadnehunk Falls. The study was originally requested by Trout Unlimited (TU). In their February 21, 2022, letter to FERC, TU requested that GLHA perform a flow demonstration study to assess whether the outage flow results in stranding of fish in pool habitats between McKay Station and Nesowadnehunk Falls. TU noted that:

> *The study will provide information regarding the potential for fish stranding associated with the Ripogenus Project. The study objective is to determine the extent and degree of danger stranding pools that occur from below the McKay Station discharge to Nesowadnehunk Falls, especially under 400 cfs generator trip events.*

TU and FERC also requested that GLHA perform a desktop evaluation to collect information about station trip events. This information is intended to identify specific conditions that lead to occasional unit shutdowns and resulting periods of low flow releases into the West Branch of the Penobscot River.

## 2.0 Resource Management Goals

The Maine Department of Inland Fisheries and Wildlife (MDIFW) manages the West Branch of the Penobscot River downstream of McKay Station and its tributaries to provide high quality habitat for spawning, nursery, and adult lifestages of a variety of fish species. The reach is especially suitable for landlocked salmon and brook trout; fluvial and lacustrine mesohabitats (including large deadwater areas and pools) provide habitat for spawning, juvenile, and adult lifestages of landlocked salmon and brook trout, as well as various other native and non-native species.

## 3.0 Study Area

As described in the SPD and in TU's request, the study area for the fish standing assessment includes the West Branch of the Penobscot River between McKay Station and Nesowadnehunk Falls.

[1] Issued by FERC on May 13, 2022.

## 4.0 Background

If unplanned conditions cause McKay Station to trip offline (resulting in unit shutdown), GLHA implements the station's minimum flow protocol, which is automated to provide an emergency outage flow of greater than 400 cfs to restore river flows to an hourly average of 400 cfs to protect aquatic habitat in downstream reaches of the West Branch of the Penobscot River as required by the Ripogenus Project license.

TU indicated in recent letters filed with FERC as part of the relicensing process for the Ripogenus Project that fish stranding occurs in large pools downstream of McKay Station during such station trip events.

## 5.0 Methods

GLHA will review operational data to identify the frequency and duration of unplanned station trips and temporary emergency minimum flow events at the Ripogenus Project that have occurred since February 2018 when the current outage procedure for implementing emergency minimum flows during an unplanned outage was implemented. GLHA will document these station trips, including a description of the start time and end time of emergency minimum flow releases from McKay Station, and the reason for each station trip.

GLHA will perform a field study in the fall of 2022 during simulated "station trip" conditions at the Ripogenus Project to provide information about fish stranding that may occur downstream of McKay Station. The simulation event will be modeled after a "typical" station trip event identified from the 5-year operational data review (2018 – 2022). The specifics of the simulation event will be developed in consultation with the MDIFW and TU and will include implementation of the Station's minimum flow protocol following the "station trip" for a duration that is representative of the average duration of such events, based on the past 5 years of data (i.e., since the current operational protocols were implemented in February 2018).

GLHA will observe stranding conditions during the simulation trip event. GLHA proposes to complete the stranding surveys in safe and accessible areas of the following areas , which are accessible, heavily fished, and known to provide habitat for cold water salmonids and other species (Figure 1):

- Big Eddy
- Nesowadnehunk Pool/Deadwater
- Telos Bridge

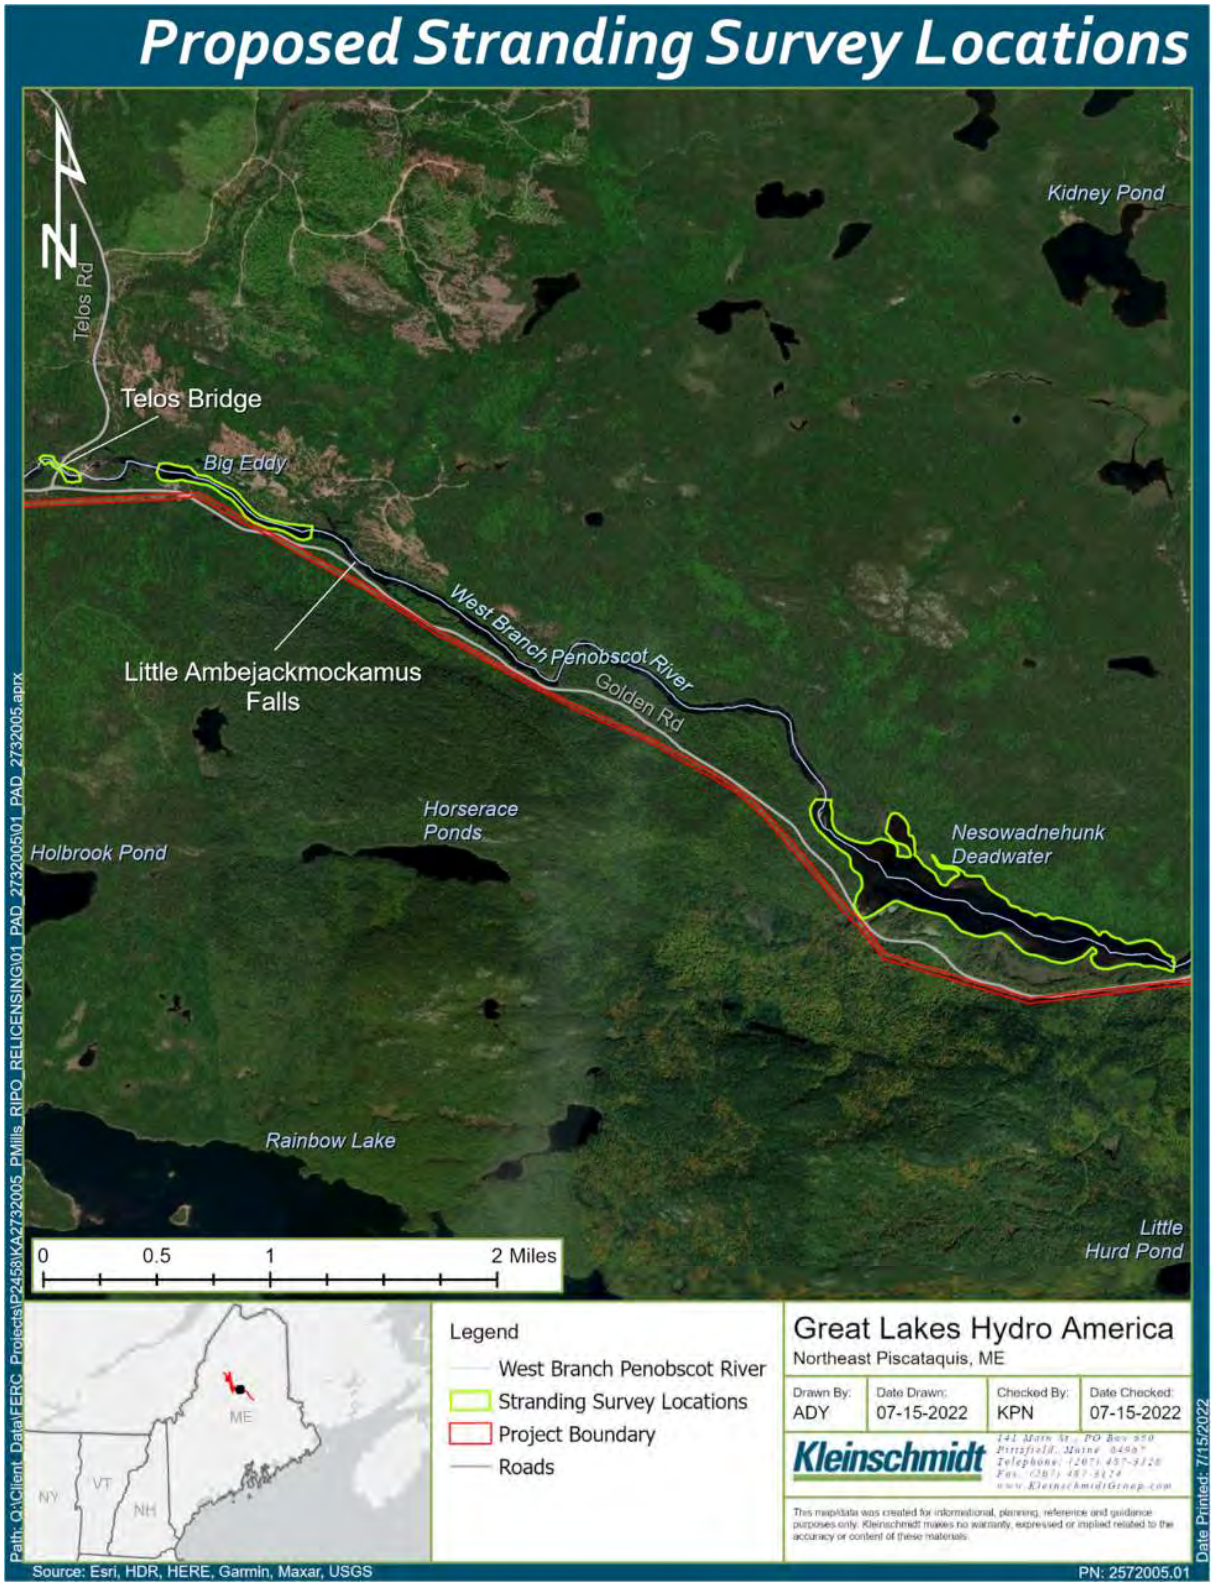

**Figure 1. Proposed Stranding Survey Locations.**

Field crews will perform reconnaissance surveys during simulated "station trip" conditions to determine whether stranding could potentially occur in these reaches during station trip conditions. Field crews will survey the perimeter of the pools on foot, by boat, or with a drone to visually document evidence of stranded fish, look for fish trapped under rocks, and to the extent possible, collect data on the species, approximate fish size, the number of fish stranded and their location, and the condition of stranded fish (e.g., stressed, injured, dead). GLHA will also take photographs or videos of stranded fish and pool habitat to document the effects of outage flow conditions on fish and habitat. If necessary, a drone will be used to supplement documentation for wide-area coverage and provide observations in areas that may be challenging to access; the drone will also provide geo-referenced, high-resolution video or still photo images.

In addition, GLHA will install a level logger in the pools to assess the duration and magnitude of the event (i.e., change in water surface elevation) that results from the outage flow release. Level loggers will be used to monitor water surface elevation for approximately 12 hours preceding and following the simulated outage flow release; loggers will be programmed to record water pressure data at 5-minute intervals. Water pressure data from the level loggers will be converted to depth of water above the logger to determine changes in water depth resulting from the outage flow.

## 6.0 Reporting

GLHA will prepare a fish stranding study report that describes outage flow operational data for the period 2018 through 2022 and summarizes the results of the field surveys during the simulated emergency outage flow release.

## 7.0 Schedule

GLHA anticipates performing the field survey in early October 2022. This time frame equates to a biologically active period for salmonids and other species, and it is outside the peak whitewater rafting season to minimize conflict with recreational activities.

# Attachment B

## Stranding Evaluation Study

***Goals and Objectives***

The study will provide information regarding the potential for fish stranding associated with the Ripogenus Project. The study objective is to determine the extent and degree of danger stranding pools that occur from below the McKay Station discharge to Nesowadnehunk Falls, especially under 400 cfs generator trip events.

**Known Resource Management Goals** (Under §5.9(b)(3) If the requester is a not a source agency, explain any relevant public Interest.)

The requestor, Maine Council of TU, is a non-governmental organization (NGO).

Maine's rivers, great ponds and wildlife are, by law, public resources. The West Branch of the Penobscot is one of the areas in Maine that TU members most prefer for fishing and other recreational activities, and thus TU has a direct interest in the waters affected by project operations, especially those from Ripogenus Dam to below Nesowadnehunk Falls.Background and Existing Information

There is no existing information regarding stranding-prone areas or operational scenarios for the Ripogenus Project. This study is needed to quantify project effects on a potential source of fish mortality and injury.

**Project Nexus**

Generator trip events at McKay Station occur with some frequency and it is a matter of record that two such events occurred during the August-September timeframe of 2021 when strandings were photographically documented.8 It is hard to image aspects of project operations that could have a more direct relationship with the welfare of aquatic organisms than immediate, drastic flow reductions.

**Methodology**

Task 1: Operational Data Review:

Prior to conducting the field investigation, a desktop literature review will be performed to gather information on the range of flows when generator trip events are likely to occur. We anticipate that since thunderstorms occur during the summer, whitewater flows generally of 2200 – 1800 cfs would generally be in effect when the outages occur.

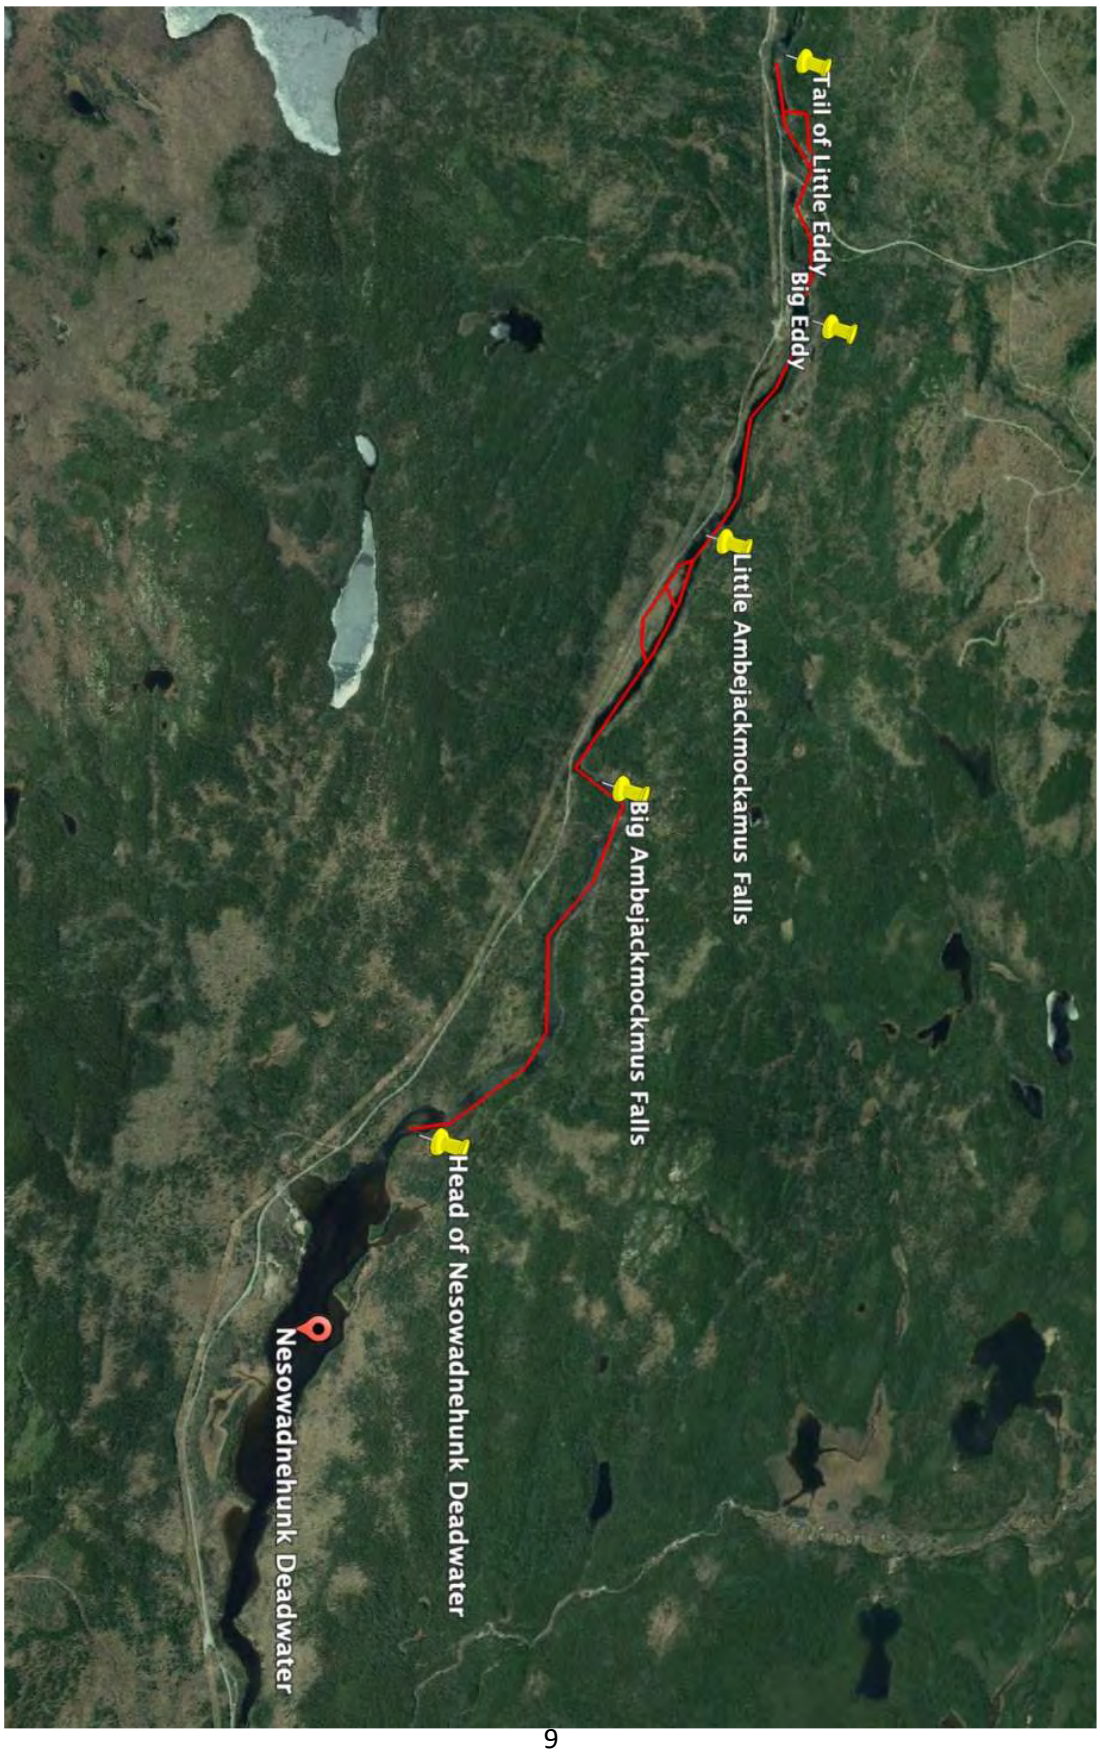
Task 2: Field Surveys:

The field survey will consist of a reconnaissance level evaluation where a field crew will examine potential stranding sites in the study area at an appropriate time interval after spilling operations have ceased. Any accessible pools with fish stranding potential will be identified and visited shortly after the spillage event. On-ground surveys will traverse any pools and visually document fish present as well as looking for fish trapped under rocks. Information on the number and location of fish stranded will be recorded. In addition, the conditions of the study area will be photo-documented.

Consistency with Generally Accepted Scientific Practice

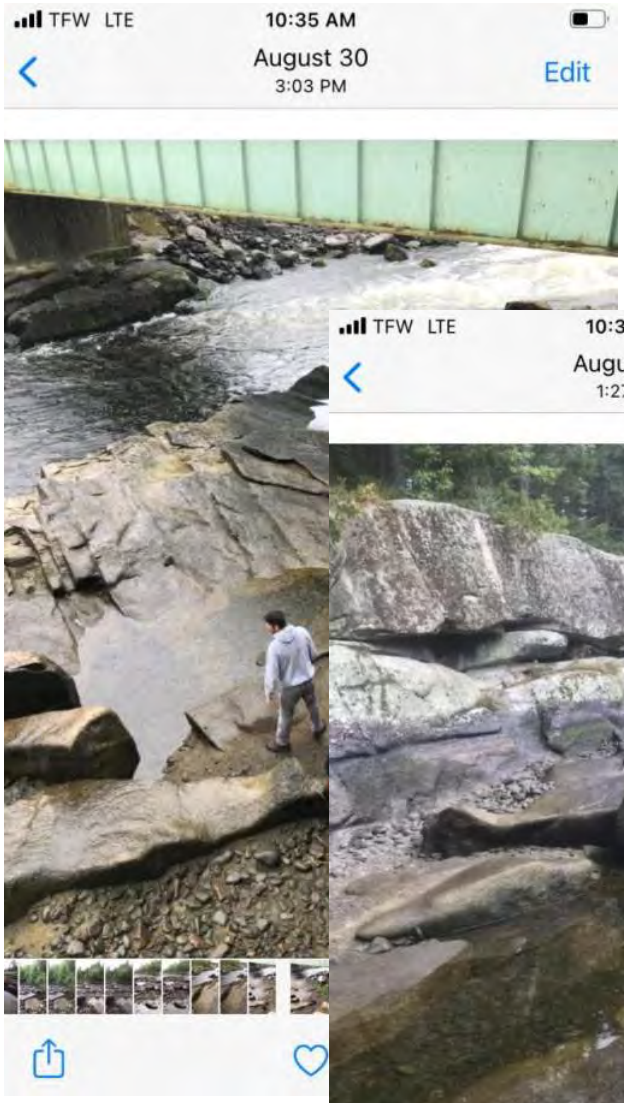
The proposed survey to document potential stranding areas is an accepted means of documenting species use in the Project area.

**Deliverables and Schedule**

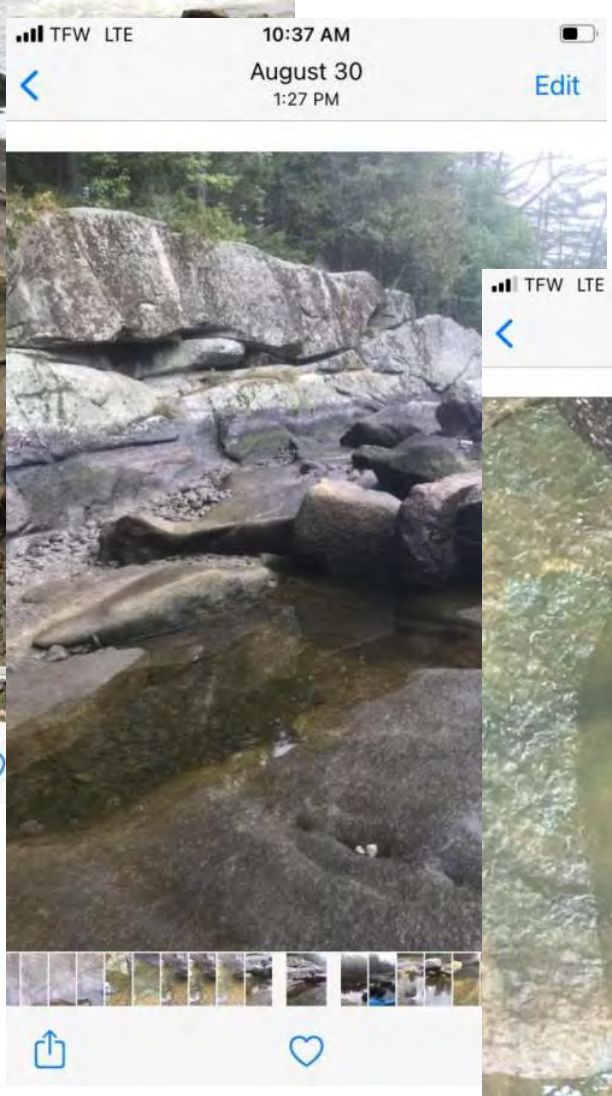


The survey effort will be conducted during the summer/fall of 2022. Data and results will be included in the Initial Study Report to be filed with FERC in 2023.

**Cost and Level of Effort**



The estimated cost for the stranding evaluation is approximately $20,000. This level of effort is consistent with the size of project operations.



The Applicant may be able to combine this study with any testing of equipment and procedures ordered by the FERC Compliance Division as part of its investigation in the low flow events previously referenced, especially generator trip events. This could provide significant cost savings lowering the cost estimate provided above.

Project No. 2572-136 : Ripogenus Project, Comments On Great Lake Hydro America's September 28-30, 2022 McKay Station Maintence Plans

In a recent Brookfield posting on their Safe Water Website, Great Lake Hydro America (the Licensee) is warning of low flows downstream of Ripogenus Dam this coming week. For the two and a half day period, West Branch of the Penobscot River (West Branch) flow will be provided through the Ripogenus Dam deep gate(s). The posted Safe Water's information is:

*Short-term schedule*

*9/28/2022 - 2 PM - 9/30/2022 11:59 PM 1100 CFS*

The scheduled West Branch flow ignores fish and aquatic communities concerns as well as fishing opportunity. Juvenile salmonids and aquatic insects along the West Branch shoreline and in side channels will be forced to move (if possible) and/or be dewatered. Of special concern is the Holbrook Bypass Channel (Article 406 of the 1996 License) and protection of juvenile salmonids, namely Landlocked salmon.

The Holbrook Bypass Channel was designed to produce young-of-the-year Landlocked salmon (salmon). The agencies considered Increases in this life stage abundance as necessary in increasing the West Branch adult salmon population. McKay Station flows of 1100 cfs do not meet either the 35 cfs or 60 cfs Article 406 flow requirements. Two salmon year classes (fry and parr) are at risk. There is no indication of agency consultation that waives these

flow requirements. It appears that the Licensee is again about to willfully violate Article 406 of the Ripogenus Project License.

The Licensee should not be allowed to arbitrarily act outside of license requirements. I request that FERC act to stop the proposed degradation of fish and macroinvertebrate communities in the mainstem West Branch and in the Holbrook Bypass Channel. Fish and macro invertebrates communities need protection.

Thank you for the opportunity to comment.

# Report of Observations – October 5, 2022
## Stranding Study of West Branch of the Penobscot River below McKay Station

Stephen G. Heinz, Maine TU Council FERC Coordinator, October 19, 2022

## Introduction

A stranding study was conducted by Brookfield Renewable (Brookfield) on October 5, 2022 to comply with the Federal Energy Regulatory Commission (FERC) Study Plan Determination.[1] Brookfield announced the study by email[2] to a small distribution of stakeholders about three weeks before the study asking for comments by September 28, a week prior to the event. The draft study plan concentrated most of the effort on the Big Eddy and the Nesowadnehunk Deadwater, areas that were unlikely to contain stranded fish, and included provision for data collection by drones. Maine Council of Trout Unlimited submitted comments disagreeing with this approach calling for "boots on the ground" and filed them to the FERC docket.[3] When it was confirmed a week prior to the event that it would go as scheduled, Maine TU Council sent out an "Action Alert" email to the Maine TU membership, and forwarded it to other organizations with possible interest. Despite the short notice, enough volunteers were recruited to man five two-person teams to observe the conduct of the study and record what they saw in a structured manner. TU received no final study plan prior to the event.

## Methods

Volunteers were instructed to assemble at Big Eddy Campground at 8:30 on the morning of October 5, 2022. A briefing was presented that covered safety, data collection, team composition and area assignment. All volunteers arrived on time, took the briefing, and signed hold harmless/photo authorization forms. Randy Dorman, assigned Brookfield licensing manager for the project, came into the briefing while in progress and expressed welcome for our presence.

Safety Instructions:

Work in pairs, keep buddy within sight and sound

Primary hazards are slipping and tripping

Take your time and do a thorough search – it's safer and more effective

If someone is injured and you have to go for help, get them out of the watercourse first

[1] Study Plan Determination for the Ripogenus Hydroelectric Project and the Penobscot Mills Hydroelectric Project dated May 13, 2022.

[2] Email from Cate Russell HDR, Subject - Ripogenus Project: Draft Fish Stranding Study Plan, September 13, 2022 at 5:04 p.m.

[3] Maine TU Council letter dated September 23, 2022, Subject: Comments of Maine Council of Trout Unlimited on the Draft Fish Stranding Study Plan.

Nearest hospital is Millinocket Regional Hospital, 200 Somerset St, Millinocket, ME 04462. This is off Route 11 just past and north of where it is joined by the Golden Road

Event set for 9:30 to 1:30. Pick a watered rock in your vicinity and check for water level periodically - everyone headed to shore at 1:00.

Brookfield may deploy drones to look for strandings. If they do, go to shore until they pass.

Don't get stuck on far bank below the Big Eddy

Water and a snack recommended

Check out before you leave – everyone must be accounted for

Data Collection Instructions:

Take an initial photo (and others if needed) showing the extent of the dewatering that the event causes.

Photo document anything alive that you find in unconnected pools - if in doubt, document

Key information: time, location, brief description*, photo #

*fish species, macro-invertebrate species, other

Use the data sheet provided if you can't keep this all on your phone

It is more important to cover area well than to cover more area

Be prepared to show what area you covered at the end of the day

Give the Brookfield crews a wide berth, do not get in their way, muddy waters, engage them, etc.

Team Composition:

| **Team #** | **members** | **affiliation** | **reach** |

Team members were given the opportunity to review this report.

Area:

TU indicated its general areas of concern in its draft study plan comments, and Figure 1[4] indicates in red those areas that stretch from the tail of the Little Eddy to the head of Nesowadnehunk Deadwater. This (including side channels) encompassed some 5 river miles more or less. Complete coverage could not be accomplished due to the limited number of volunteers available on the short notice provided for the Brookfield study.

**Figure 1**

General. Each team was given a black and white paper map showing desired observation areas. These areas were based on a best guess of where strandings would be most likely to occur based on past strandings and cursory analysis of the topography. White lines indicated general areas of interest. Please note that these areas differed significantly from the areas that Brookfield proposed in its draft study plan[5] that devoted most of its area coverage to the Big Eddy and the Nesowadnehunk Deadwater, areas that were unlikely to contain stranded fish due to their topography which is predominately composed of deep runs and large pools of

[4] Id., Attachment C.

[5] Draft Stranding Study Plan forwarded by Email from Cate Russell HDR, Subject - Ripogenus Project: Draft Fish Stranding Study Plan, September 13, 2022 at 5:04 p.m.

significant depth that could be dewatered per the study parameters but still retain several feet of water depth. Specific TU observation area descriptions follow, corresponding maps are included as attachments due to size. The white line indicates areas of general interest, yellow shading indicated general areas each team was able to actually cover and make first-hand observations, red areas indicate those where a relatively high incidence of strandings were observed. Assigned coverage areas were less than those shown in Figure 1, actual coverage by the teams within assigned areas was less than the entire reach as teams tended to cover areas that showed the most potential for strandings as the water receded. Team 3 was not able to cover an area of likely strandings due to the rugged character of the dewatered terrain. The teams furthest downstream started latest waiting for the water levels to drop, but were required to leave the water course by 1:00 PM. This put them at a time disadvantage, but they found significant numbers of dead and stranded fish and stranded macro-invertebrates.

Holbrook side channel. The Holbrook side channel and portions on the north bank between the tail of the Little Eddy and where the side channel rejoins the main stem of the river. The map is included as attachment A.

Holbrook South. The south bank of the main channel between the tail of the Little Eddy and Telos Bridge. The map is included as Attachment D.

Cribworks. Area from Telos Bridge to the head of the Big Eddy. The map is included as Attachment G.

Little A Falls. South bank and side channels of the area below Little A Falls. The map is included as Attachment J.

Big A Falls. The east and south banks of Big A Falls and area downstream of the falls to the first riffle. The map is included as Attachment M.

## Results

Flows prior to the event appeared to be consistent with the representative 2200 cfs TU had requested in its comments of the draft study plan. The event appeared to commence on time – 9:30. There were noticeable differences in time lags required for flows and levels to drop at the various areas downstream where the volunteers were prepositioned. Vertical drops in water levels varied between areas based on bottom topography. By 2:30, levels and flows at the Big Eddy appeared consistent with the 1700 cfs post-event target flow. Subsequent reporting by Brookfield[6] showed restoral of target flows at 1:57 p.m., a 4 hour and 28 minute outage. It should also be noted that the initial trip flow was reported as 12 cfs but went to 400 cfs quickly.

[6] Brookfield letter dated October 12, 2022, Subject: Ripogenus Project (FERC No. 2572); Planned Minimum Flow Modification.

A significant number of strandings occurred that resulted in observed fish mortality. All five teams reported fish and macroinvertebrate strandings, four teams reported dead fish, including salmon parr, brook trout, dace, sculpin and unidentified minnows; Team 1 did not report dead fish, but uploaded a short movie showing a fish in a drying pool that could not have survived. The good news was that the Holbrook side channel functioned as designed and remained watered from bank to bank. This is a constructed feature designed to provide spawning and nursery habitat for salmonids. This was a remediation measure included in the current license that MDIFW and Brookfield share credit for making work effectively to improve the greatly modified resource that the West Branch of the Penobscot represents.

| Team | Fish* | Minnows# | Dead fish & minnows | Invertebrates |
|---|---|---|---|---|
| 1 | 8 | 12 | 0 | Many |
| 2 | 2 - 3 | 12 | 9 | 100s of nymphal insects, 12 crayfish |
| 3 | 14 | 2 | 1 | Too numerous to count |
| 4 | 45 | 30 | 15 | Countless |
| 5 | 10 | 35 | 35 (all the fish, 25 minnows) | 95 counted |
| Total | 79-80 | 91 | 60 | Much too numerous to count |

* Fish were defined as all salmonids and others over 2 inches in length

# Minnows were defined as fish under 2 inches in length

Fish. Landlocked salmon parr were the predominant fish species stranded. Brook trout were observed as well.

Invertebrates. Macro-invertebrates were present in tremendous abundance. Species included golden stonefly nymphs (Perlidae), black stonefly nymphs (Pteronarcyidae), green rock worm (Rhyacophila), dragon fly nymphs (possibly family gomphidae genus hagenius and family cordulegastridae, genus cordulegaster), hellgrammites, crayfish, leeches and others.

Minnows. Species included black-nose dace, sculpin, and others.

Photography. Selected team imagery is included with the attachments that are organized by teams. Additional imagery is available for viewing online at https://drive.google.com/drive/folders/1ssnvwFOlQhT_fn93gN1Vk1la1chPv53S?usp=sharing

Team 1 included a short movie of a landlocked salmon trying to escape from a disconnected pool and another in a pool that was drying up. Team 2 offered a Power Point presentation describing the images it contained. Team 3 included short videos of multiple salmon parr stranded in a small pool and another of a salmon parr struggling on ledge trying to reach water. Team 4 included 8 movies, mostly of stranded fish in pools. The remainder of the images are still images.

## Discussion

Area Coverage. The actual area that the 5 volunteer teams was relatively small compared to the area specified in the FERC Study Plan Determination[7] or as defined in TU comments on the draft stranding study plan.[8] The teams deployed furthest downstream could have stayed on task longer due to the time lag required for water levels to rise, but this course was not taken in the interests of safety. A ballpark figure for the actual coverage was 5 to 10 % of the area FERC specified in the SPD.

Substrates. Three substrate scenarios where strandings occurred when dewatered were noted: ledge with depressions, mixed boulder and gravel, porous gravel. Sloping banks were not generally conducive to strandings regardless of substrate.

Predation. Predation was likely higher during the event. Besides strandings, such a precipitous water level drop causes disorientation and stress to aquatic species. Team 2 observed a merganser consuming a salmon parr in a pool of reduced size, Team 3 observed crows on the banks likely consuming stranded macro-invertebrates.

Mortality Factors. Conditions were relatively benign during the event with air and water temperatures mostly in the 60s. Dead fish were observed by all but one team, and this would have likely been more severe if conditions during the event more closely resembled those expected to cause an unplanned trip event: a thunderstorm during the hottest part of the summer, a northeast storm during the coldest part of the winter. It remains unknown how far downstream the effects of the event persisted. The furthest downstream observations were taken about four miles downstream from McKay Station. One would expect for the effects to continue at least another mile downstream to the head of the Nesowadnehunk Deadwater. It would be difficult to determine mortality in the deadwater because dead fish tend to sink and the pool is deep. Adverse effects could continue further downstream to the next impoundment, North Twin. Fish size also seemed to be a significant factor: smaller salmonids and minnows were less likely to survive than larger fish. Duration of the event would also play a major role in mortality rates of stranded fish: the longer the event, the higher the mortality.

Larger Ecological Effects. Few dead macro-invertebrates were observed. Again, relatively benign conditions likely contributed to this. Had the event occurred during sub-freezing or extremely hot weather, it is safe to assume more macroinvertebrate mortality would have been observed. For example, and there are many, one stranded dragonfly nymph was found 20 feet from any water, that may have perished in the event. It is safe to assume that the trip event did not benefit any of the aquatic species, the magnitude of the harm is difficult to determine. Dewatering of aquatic vegetation also occurred. Again, this could have no positive effect, the magnitude of the harm is difficult to determine.

[7] SPD, page B-4: "...downstream from the McKay Station discharge to Nesowadnehunk Falls."
[8] Maine TU Council letter dated September 23, 2022, Subject: Comments of Maine Council of Trout Unlimited on the Draft Fish Stranding Study Plan, page 2.

## Conclusion

The observations conducted by TU teams deployed during the October 5, 2022 trip event demonstrate that significant fish stranding and mortality occur downstream from McKay Station when flows are reduced abruptly from 2200 cfs to 400 cfs. The incidence of mortality could be expected to increase further during dewatering events that occur in extremely hot or cold weather conditions when exposure to very warm or freezing air temperatures will more immediately impact the body temperature of stranded organisms.

Clearly, further data beyond what are contained in this report are required to determine the minimum flow required to prevent these strandings or if ramping flows would be less harmful to the aquatic life in the affected reach. The Initial Study Report from Brookfield is not due until May 13, 2023.[9] We trust that it will be consistent with our observations, and if it does not include empirical data indicating flows and duration of dewatering required to prevent future mass strandings, that Brookfield will propose additional studies to determine that.

yellow: coverage area; red: high stranding area

## Attachment B

Debrief Sheet – Team 1

Team Members: David Bean and Max Tritt

Reach: Holbrook side channel

Percent Coverage: 70 %

Shot showing dewatered area: Yes, outside of the side channel

Number of stranded fish: 20 plus

Number of stranded invertebrates: many, mostly stonefly nymphs

Number of stranded others: minnows including common shiner, and black nose dace

Narrative: The team started their observations on the lower Holbrook reach at 9:33 and went upstream from Telos Bridge to the entrance of Holbrook side channel arriving at 10:00. Around the entrance to the side channel, we observed over 20 fish stranded in pocket water, mostly common shiner, black nose dace, brook trout and landlocked salmon parr – mostly young of the year but one salmon was over 7 inches in length. The flow in the Holbrook side channel was bank to bank and all of the stream habitat there was wetted and continuous, no stranded fish were observed in the Holbrook back channel. While no dead fish or minnows was observed, it was assumed that some would have succumbed in time. The team returned to the campground at 1:00.

The short movies may be viewed at –
https://drive.google.com/drive/folders/1ssnvwFOlQhT_fn93gN1Vk1la1chPv53S?usp=sharing

## Attachment C

|---|
| yellow: coverage area; red; high stranding area |

## Attachment E

Debrief Sheet – Team 2

Team Members: Mike Enos and Jim Hayes

Reach: Holbrook South

Percent Coverage: 55%

Shot showing dewatered area: yes

Number of stranded fish: 2 or 3 landlocked salmon parr (overhanging rock prevented a sure count)

Number of stranded invertebrates: hundreds of nymphal insects, 12 crayfish

Number of stranded others: 12 minnows

Narrative: After arriving at our area at about 9:30, we took GPS coordinates at three access points to the river on the south bank.

The furthest access point upstream was where Holbrook Brook joins the river. There was a small island that formed when flows dropped and numerous unconnected pools. All pools contained stranded animals and plants. This section of our reach included:

2 or 3 salmon. Note: a merganser was photographed consuming a disoriented fish in a shallow but connected pool.

3 crayfish

100s of nymphal insects

Several minnows including one dace and other chub-like ones

We then proceeded to the access point furthest downstream. This section of the reach contained stranded minnows, nymphal larvae, and crayfish.

The area nearest the middle access was checked last. Not as many pools formed there. The drop to the river was steeper along this shore and not much was seen for stranded type pools and no fish or crayfish were seen here along this shore. A few insect nymphs, but no crayfish, minnows, salmon, etc. No Photos were taken here of organisms. Just a photo showing the view along the river.

We left the area at noon, and returned to the campground area. A Brookfield field crew and drone were observed in this reach.

## Attachment F

Selected photos, additional available at https://drive.google.com/drive/folders/1ssnvwFOlQhT_fn93gN1Vk1la1chPv53S?usp=sharing

Debrief Sheet – Team 3

Team Members: Charlie Spies and Steve Heinz

Reach: Cribworks

Percent Coverage: 60%

Shot showing dewatered area: multiple

Number of stranded fish: 14, included one dead YOY salmonid

Number of stranded invertebrates: too numerous to count. Macro-invertebrates included black and golden stonefly nymphs, green rockworms, dragonfly nymphs, crayfish and leeches

Number of stranded others: numerous minnows including black-nosed dace

Narrative:

Team arrived at Telos Bridge at 9:25. At 9:30 AM Brookfield Power rapidly reduced main stem river flow from MacKay Power Station to 400 Cubic Feet per Second (CFS) from 2,200 CFS. This was done to simulate minimum downstream flows when the station turbines are shut down for repairs or load leveling. It is generally assumed that this occurs approximately four times per year due to unexpected demand interruptions or repairs. By 10:00 AM our team had observed a significant drop in the river level which seems to stabilize at the Cribworks reach at approximately four vertical feet below the higher flow observed before the simulated "trip event."

1) Cribworks Area (see map Attachment G): Time in 10:00AM; Time Out 11:25AM.

During the observation period, Team 3 covered approximately 60 % of the dewatered river edge areas. Dewatered areas were readily identified by moisture on the rocks and exposed plant growth that typically occurs below water level. The color difference between freshly dewatered shoreline and normally dry shoreline was dramatic and enabled differentiation, captured by photos P1-P4: full flow conditions (9:30 AM) and dewatered views (10:00AM) from Telos Bridge on north bank and and south bank respectively.

Team 5 descended to the south bank below Telos Bridge at 10:00 AM. We immediately found stranded fish and macroinvertebrates in the dewatered area (Photo 5 – Crayfish; Photo 6 Stonefly; Photo 7 Leech - all taken at ~10:04 AM). Definition of fully isolated pools became clear as water receded further from riverbed (Photos 8 and 9 10:16 AM).

At 10:20 AM we observed fish stranded in isolated pools (confirmed salmon parr and brook trout (Photo 10) and a salmon parr that attempted escape from a small pool but returned to the pool on its own. Same fish in same pool was recorded again at 10:44AM (Photos 11-13).

Multiple isolated pools containing stranded macroinvertebrates (stoneflies, crayfish, mayflies) and salmonids were observed during the period between 10:20 and 10:45 (Photos 14-18). The team also

observe a likely high-stranding area further downstream on the south bank but deemed it too dangerous to enter (Photo 19). The team left the south shore at approximately 10:45 AM to survey the opposite (north) bank.

The team surveyed the north bank beginning at approximately 11:07 AM (Photo 20 shows a portion of the reach upstream to the Telos Bridge; Photo 21 shows downstream portion). The team found a different topography than on RR. River left was steeper and seemed to allow for water to recede without creation of isolated pools. No fish stranding was sighted. However, sightings of multiple stranded macroinvertebrates in the dewatered area were common. Very often stonefly larvae and crayfish were found on dewatered rocks and sand as far as 15 feet from the main new low-water line (Photos 22 and 23). It seems unlikely they would successfully migrate to the water line from such a distance, especially the insect nymphs which are subject to desiccation. The team also observed crows actively feeding in the dewatered area and it seems likely that they were taking advantage of the exposed food bonanza of stranded macroinvertebrates.

The team exited the Cribworks reach at approximately 11:25 AM.

Culvert Pool Reach: Time in: 11:35 AM and Time out: 12:05 PM

At approximately 11:30 AM the team drove about ¼ mile below the Telos Bridge on river left to a reach called the "Culvert Pool" (see Attachment G). The topography was flatter than the north bank upstream at the Cribworks Photos 24 and 25). Some isolated pools were observed, including on containing Black-Nosed Dace (Photo 26) and much of the dewatered area exhibited multiple stranded macroinvertebrates, including stonefly nymphs and crayfish with lesser populations of caddis fly nymphs and dragon fly nymphs (Photo 27 shows a dragon fly nymph located 20 feet from the water line). Many of these insects and crayfish were found between 15 and 20 feet from the water line. Crows were observed feeding in this area.

Our team left this area at approximately, 12:10.

Side Channel below Cribworks and feeding Culvert Pool River Right: Time in: 12:20 PM; Time Out 12:50 PM

This side channel (Attachment G) was traversed for its entire length until it emptied into the main stem above the Culvert Pool Reach on river-right. It is not a main channel in the river and is approximately 20 feet across and slow-flowing when compared to the main stem. It is separated from the main stem by an island. The channel was deep with steep sides and remained mostly well-watered. Few isolated pools were observed. No stranded fish were observed and few stranded macroinvertebrates were observed.

Summary of Team 3 Observations:

Dewatering CFS from 2,200 to 400 resulted in significant and rapid river level decline (over 30 minutes to lowest level at the Telos Bridge location). This clearly impacted both fish populations and macroinvertebrate populations. Depending on riverside topography the impacts on fish varied. Where the dewatered river's edge was relatively flat a significant number of isolated pools emerged with stranded fish. Many of these continued to drain via the porous sand/rocky river bottom and resulted in fish trying to exit over land and stranding out of water. The south bank area below Telos Bridge is a

good example. Of the number of stranded fish observed by our team, approximately 20, (some isolated pools may have held more fish than we could directly observe), we spotted several fish that were either fully stranded and dying or likely to die due to lack of water or adequately oxygenated water before stream levels recovered later in the day (after 1:30 PM). Fish mortality for those stranded is estimated to have approached 20% given our observations.

In all areas observed river level decline was significant at 3 – 6 feet depending on topography. In all observed areas stranded macroinvertebrates were common and abundant in dewatered edges. In some cases, stranded populations were observed as far as 20 feet from the river's low water edge. Mortality of insect larvae seems extremely likely. At the time our observations were made air temperature was in the low 60-degree Fahrenheit range. The incidence of macroinvertebrate mortality could be expected to increase further during dewatering events that occur in extremely hot or cold weather conditions when exposure to very warm or freezing air temperatures will more immediately impact the body temperature of stranded organisms.

Prior coverage of the north shore and area just above the Big Eddy by a Brookfield field crew may have affected our results. The crew had a dip net, they may have returned some stranded fish to flowing waters. Most of our stranding fish were discovered in the first hour of investigation in an area the Brookfield crew had not covered – we believe that most perished. We did not return them to flowing waters because we did not want to affect the results of the Brookfield study. Two short movies were recorded: one shows a disconnected pool containing multiple landlocked salmon parr, the other a landlocked salmon parr flopping on ledge trying to escape a small disconnected pool. These and photos not included in Attachment I but can be viewed at -

## Attachment K

Debrief Sheet – Team 4

Team Members: Julie Puleio and PJ Smith

Reach: Little A Falls

Percent Coverage: 50% plus of south shore with additional coverage of north shore, back channels were not covered.

Shot showing dewatered area: yes

Number of stranded fish: over 45, 15 dead

Number of stranded invertebrates: many including 100s of stonefly nymphs and some crayfish

Number of stranded others: ~36 shiner minnows, many other dead fry

Narrative:
The team arrived at the boat takeout at 9:40 and began to walk upstream [west], but it would be an hour before flows began to drop.

We walked to the point just downstream of Little A Falls and continued on the south shore down to the boat takeout. At 10:30am, we saw countless black and golden stonefly nymphs and approximately three dozen stranded shiners along one stretch of the shore (example images collected between 10:28am and 10:39am).

By 11:00am, low flows had exposed a wadable route to the north shore that we could see contained disconnected pools. Enroute, we found a pool with 5 stranded trout and salmon (example image 10:50am). By 11:45am, the pool had dried up and the fish had perished (example image 11:50am). In the remaining time on the opposite bank along Little A falls, we observed at least 40 stranded salmon in 8 disconnected pools; at least 10 of the salmon were dead. Multiple images and videos captured between 11:09am and 11:21am highlight this. The pools also contained hundreds of stranded stonefly nymphs and a number of crayfish.

After investigating the dried pool we returned to the north bank, this time further downstream (highlighted as the second, red high stranding area.) Here we also discovered approximately a dozen disconnected pools with one to many parr in each. Images and videos captured between 12:03pm and 12:06pm EST highlight this.

We began walking out at 12:45pm. We did not have time remaining to investigate the side channels that were part of our assigned area, as our observations lead us to investigate the north banks more heavily.

Eight short movies were taken during the course of the team's investigation. They may be viewed at - https://drive.google.com/drive/folders/1ssnvwFOlQhT_fn93gN1Vk1la1chPv53S?usp=sharing

Debrief Sheet – Team 5

Team Members: Rory and Angela Hannon

Reach: Big A Falls

Percent Coverage: 80%

Shot showing dewatered area: Multiple

Number of stranded fish: 10, half were dead

Number of stranded invertebrates: many including stonefly nymphs, dragonfly nymphs, hellgrammites, and crayfish

Number of stranded others: minnows included sculpin, black nosed dace and others.

Narrative: The team started at the raft takeout at the base of Big A Falls at 9:30 and walked downstream along the south bank and observed stranded macroinvertebrates, minnows, sculpin, crayfish and salmon parr. We then walked back to the base of the falls and started south where we also found many stranding of the above-mentioned organisms. We left the area at 1:00.

***Via Electronic Filing***

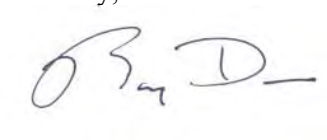
Kimberly D. Bose, Secretary
Federal Energy Regulatory Commission
888 First Street, NE
Washington, DC 20426

**Subject:** **Ripogenus Hydroelectric Project (FERC No. 2572-133)**
**Penobscot Mills Hydroelectric Project (FERC No. 2458-247)**
**Second Study Progress Report**

Dear Secretary Bose:

Great Lakes Hydro America, LLC (GLHA), Licensee of the Ripogenus Hydroelectric Project (FERC No. 2572) and the Penobscot Mills Hydroelectric Project (FERC No. 2458) (collectively referred to as the "Projects"), herein files with the Federal Energy Regulatory Commission ("FERC" or "Commission") the Second Study Progress Report for the relicensing of the Projects. The Projects are located on the West Branch of the Penobscot River and Millinocket Stream in Piscataquis and Penobscot counties, Maine.

The current licenses for the Projects were issued on October 22, 1996 and expire on September 30, 2026. On June 11, 2021, GLHA filed the Notices of Intent and Pre-Application Document, which initiated the formal relicensing proceeding to obtain two separate new licenses for the continued operation of the Projects through the Commission's Integrated Licensing Process (ILP). On March 23, 2022, GLHA filed a Revised Study Plan (RSP) for the Projects, and the Commission issued the Study Plan Determination (SPD) on May 13, 2022.



Pursuant to the RSP, GLHA herein submits the Second Study Progress Report for the period from August 1, 2022 through October 31, 2022 for the Projects. The enclosed table (report) provides a list of the required studies and associated status of progress, as well as any modifications to the approved methodologies.

Concurrent with this filing, GLHA is providing a copy of this letter to all parties listed in the attached distribution list. A copy of the Second Study Progress Report can be downloaded from FERC's eLibrary system at https://www.ferc.gov/docs-filing/elibrary.asp by conducting a search using the docket numbers p-2458 and/or p-2572.

Project No. 2572-132 : Ripogenus Project, Support and Comments on Trout Unlimited' s *Report of Observations on Ripogenus Project Fish Stranding Study* filed October 19, 2022.

On May 13, 2002 FERC filed a Study Plan Determination (SPD) that required Brookfield Renewable Energy/ Great lakes Hydro America (collectively the Licensee) to conduct a fish stranding study on West Branch of the Penobscot River (West Branch) below McKay Station. On September 13, 2022 the Licensee submitted a draft Stranding Study Plan (Plan) to determine the impacts of McKay Station outages or "trip" flows on West Branch fish, namely salmonids. The Plan stated that a study of fish stranding below McKay Station would be conducted on October 5, 2022. The Licensee asked for comments by September 27, 2022. Given that the Licensee had four months of advance knowledge of the FERC SPD that mandated this study, the filing request for comments and scheduled study date were not provided to stakeholders in a timely manner. Licensing is intended to be collaborative process involving the stakeholders. The timeline provided prevented this from happening.

It should be noted that the Licensee's Plan referenced the need to avoid interfering with recreationists, anglers, and boaters. This sad commentary demonstrates the Licensee's lack of knowledge of current recreational use e.g., anglers and boaters of the West Branch below McKay Station. During the last weeks of August, Monday-Wednesday daytime use e.g., kayaking, rafting, is minimal to nonexistent. Angler use is also minimal with peak activity in the evening. There was no need to delay the FERC mandated study for months because of angler and rafting concerns. Moreover, and ironically, the Licensee has no such qualms of the impact of peaking or minimum flow operations on recreational/angler use of the river during "normal" operations.

On September 21, 2022 I filed a comment/complaint arguing that the Licensee's September 15, 2022 Draft Outage Study Plans were inadequate and suggested

changes. I also referenced the Holbrook Bypass channel (Bypass) and the unique circumstances created by 2021-2022 low flows.

The Holbrook Channel Bypass Area

The artificially watered Holbrook Bypass Channel (Article 406) stranding issues differ from main channel concerns as there were likely no or few juvenile salmon present during the study. The Bypass was a major mitigation measure required by the 1996 License and was developed to supplement West Branch juvenile salmon production. Flows into the Bypass area are controlled by two gated pipes that extend from Holbrook Pool into the Bypass. Inflow is set at 30 or 60 cfs depending on salmon life stage and season.

On May 9, 2022 I filed comments on the winter 2021-2022 License Article 406 flow violations and discussed the impacts of low McKay Station flows during the Landlocked salmon (salmon) spawning and incubation season. Winter 2021-2022 flows were extremely low. Spawning success and subsequent 2022 juvenile salmon (eggs spawned in November 2021) production in the Holbrook Bypass were unlikely. The Licensee has not disputed this claim.

Members of the NOAA surveyed the Bypass area on October 5, 2022 and reported no stranding of salmonids. Photos of the Bypass area show a watered channel, a stream segment NOT suitable to juvenile salmon production or long-term survival. There were several low flow events in the summer 2022 “salmon nursey season” and NO suitable spawning and incubation flows in the winter of 2021-22. Thus, 20+ years of on-site work experience and professional judgment suggests that there were few, if any, juvenile salmon available to be stranded. MeDIFW may have recent (2018-2022) electrofishing survey data that are relevant to this issue.

The biological, seasonal, temporal, and spatial, issues that were not, or only partially addressed by the Licensee’s Plans were:

Biological – In the SPD, FERC Staff stated: “Rapid changes in flow and decreases in water surface elevation can increase the risk of fish and invertebrate stranding which may be stressful and/or lethal for aquatic organisms.” The West Branch macro invertrabrate communities support all salmonid life stages and are especially critical to adult salmon during the summer maintenance feeding period. The Licensee’s

initial study plan made no reference to macro invertebrates. Clearly the Licensee ignored FERC concerns expressed in the SPD. Hopefully the Licensee included aquatic communities in their final study plan and the October 5, 2022 field survey.

Juvenile salmon, notable alevin (the salmon life stage that leaves the redd around June 7th), grow into fry that are, larger and more mobile in October than in June and July. A Fall flow study ignores these changes (habitat selection, activity, mobility) in vulnerabilities. As waters cool and the growing season ends, salmonid and macro invertebrate activity declines as juveniles move out of shallow high velocity areas.

Seasonal – During the fall as waters cool, salmonids and macro invertebrate seek deeper water habitats and become less active. During the cooling period, growing season habitats support fewer individuals as juvenile salmon migrate from shallow riffle areas e.g., Ladd Hill Stream "run around", the Little A Falls "run a round", etc., into deeper water. In all cases, vulnerability to stranding is reduced as juvenile salmon move to these deeper river habitats.

The Licensee's Plan states "GLHA anticipates performing the field survey in early October 2022. This time frame equates to a biologically active period for salmonids and other species, …..". Currently, West Branch water temperature data are not available. Possibly water temperatures were above 50-55 f degrees the first week of October. The Licensee should provide minimum/maximum daily temperature data for the September 28 to October 5, 2022 period along with peer reviewed references to support their statement.

Temporal – Biological and seasonal behavior of fish and aquatic communities are linked to stream flows, temperatures and photoperiods; the bias caused by a Fall study when stream temperatures have dropped cannot be ignored (see above paragraph). This is compounded by the fact that fish and macro invertrabrates stranded or trapped in "side pools" would be less vulnerable to stranding/or isolation and subsequent mortality. Thus, the full impact of June-August emergency McKay Station outage/trip events will remain unknown.

Spatial – Initially, the Licensee proposed study sites which included slower, deeper habitats, not representative of the species and life stages at risk. Sample sites such as the Big Eddy and Nesowadenhunk Deadwater are not representative of river reaches with shallow high velocity habitats that increase vulnerability to fish and

aquatic communities stranding. It is unknown if the Licensee added additional observation sites.

Study Results

On October 5, 2022 the Licensee implemented its version of a Trout Unlimited (TU) Study Request of the impact of McKay Station emergency outage or "trip" flows on the West Branch. It is not known if aquatic communities were included or if the Licensee expanded their study area. The Licensee's report will be provided at a later date.

Fortunately, despite short notice, TU was able to assemble four two person teams and NOAA provided a two-person team. These lay teams and NOAA produced conclusive results while covering a number of critical river reaches NOT proposed by the Licensee. TU's observations filed October 19, 2022 provide a grim picture of the impact of McKay Station shutdowns and subsequent low flows (approximately 400 cfs) on fish and aquatic communities. Cursory study results including TU's graphic pictures of dead or moribund salmonids and macro invertrabrates confirm suspected major impacts on these communities.

TU's outage/"trip" request only dealt with the area immediately downstream of McKay Station continuing to below the Big Eddy; the area of angler usage and complaints. It appears that TU's observations efforts ended at the head of Nesowadnehunk Deadwater. Areas downstream of Nesowadnehunk Deadwater provide critical habitat for juvenile West Branch salmon and further downstream, North Twin Impoundment (P2458) juvenile salmon (results of upstream spawning migration). However, the Licensee's study design failed to identify the magnitude and duration of "downstream" impacts and consider the entire 21 mile stretch of river.

While not part of TU's initial study request, the lower end of the 21-mile West Branch reach below McKay Station provides spawning and nursey habitat for salmon from the both the reach between McKay Station and Pockwockamus Falls as well as the North Twin Impoundment salmon(see 1992 North Twin Project FERC Application). A Maine Department of Inland Fisheries and Wildlife (MeDIFW) tributary spawning study request (October 8, 2021 *Study Request 8: Landlocked Salmon Habitat Use/Spawning Study—Penobscot Mills Project*) made by the MeDIFW Enfield office emphasized the importance of this lower river reach and the

continued production of naturally spawned (as opposed to stocked) salmon. Significant salmon recruitment to the North Twin impoundment is limited to juvenile fish from Nahmakanta Stream and the West Branch above Ambajejus Lake. Loss of West Branch salmon recruits through dewatering severely compromises MeDIFW's North Twin salmon management goals. The fact that reaches downstream of Nesowadnehunk Falls were excluded from the Licensee's Study Plan was a major flaw and outage flow downriver impacts need to be addressed.

Operational Issues

The Licensee's initial study plan called for a simulation of a McKay Station "trip"/outage during "normal" generation. Given the Licensee's recent operational history of varying generating flows, "normal" is a bit vague! It appears station flows were at 2200 cfs at the time of the trip/outage study. During the weeks prior to October 5th McKay Station flows ran as low as 1100 cfs for a two day period including September 29th (archival data are not available). These flows effectively dewatered aquatic habitat above the 1100 cfs flow level. Unless the Licensee can produce peer reviewed publications that prove aquatic communities can recolonize dewatered shoreline habitats during a six-day period of reduced biological activity, the study results apply only to the aquatic zone below the 1100 cfs shoreline elevation set by the late September two day low flow.

The Ripogenus Project was within normal "rule curve" storage (see 1992 FERC Application) limits during September. There was no biological need to reduce September 2022 flows to the licensed minimum to meet North Twin Impoundment elevation Lake trout spawning goals. Lake trout reproduction is no longer a fisheries MeDIFW management goal.

> *In the February 22, 2022 filing MeDIFW wrote "However, after periodic lake trout monitoring during the early 2000's it was determined wild lake trout reproduction was not occurring in the impoundment. Therefore, Article 408 was amended in 2012 to remove the minimum target lake elevation level during the period August 22 through October 15. With the minimum target lake elevation now removed, MDIFW believes that the Project's seasonal drawdown cycles could have a negative impact on wild landlocked salmon movement, spawning, and incubation within the impoundment and its tributaries*."

Given normal October 2022 Ripogenus storage availability was well within Rule Curve guidance, a pre-study flow of 1100 cfs makes little biological or hydraulic sense and only served to degrade study results.

TU's effort on October 5th produced data of great value to the licensing process. These results demonstrate the loss of small fish, most importantly small salmon, and aquatic insects. TU's October 5th study results provided insight into direct and immediate impacts, stranding, on fish and aquatic communities. The Study requirement and draft study design did not include secondary or delayed impacts caused by flow reductions, namely increased fish movement and commonly referenced increases in insect drift (Cushman, R (1985), Dewson et al (2007), James et al, (2008), Mishal and Winger (1968), Perry and Perry (1986). Displaced aquatic insect that are washed (drift) downstream are lost as a critical food source to fish in the immediate area. The volume of drift and long-term impacts are unknown and need to be defined.

TU's cursory study finding clearly demonstrate the degradation of West Branch fish and aquatic communities resulting from erratic flow management in a river once famous for its landlocked salmon fishery and angler use. Unfortunately, major data gaps remain, namely macro invertrabrate species, seasonal (the date of any outage/"trip" event), baseflow issues and lower river impacts. These gaps need to be addressed.

TU's preliminary study findings clearly established the impact of outage/trip flow on West Branch fish and aquatic communities. There is now a well-documented need for higher minimum base flows, ramping and an increase in outage/"trip" flow protection. Current peaking flows and station outage/"trip" events degrade all aquatic communities in the 21 mile reach and impact MeDIFW's fisheries management goals. The new License and accompanying 401 WQC will include provisions that will affect the biological communities and recreational activities of the entire 21-mile stretch of river and will not be limited to the single 5-mile reach observed in the October 5, 2022 study.

The Licensee's June 2021 Preliminary Application boasts of Protection, Enhancement and Mitigation Measures. There is little evidence that the Licensee has adhered to

these claims. FERC should act in any manner possible, now and in the future, to protect the 21-mile West Branch fish and aquatic resources. A balancing of the resources is needed.

Thank you for the opportunity to comment on this process.

**RE: Downstream Eel Passage Standard - Maine**

Dear Secretary Bose,

On May 23, 2017, the Department of the Interior, through the United States Fish and Wildlife Service (Service) submitted its Preliminary Prescription for Fishways (Prescription)[1] for the Mattaceunk Hydroelectric Project (Project; FERC No. 2520) and finalized that Prescription on June 27, 2018.[2] On February 26, 2021, the Federal Energy Regulatory Commission (FERC; Commission) issued a new license (License) for the Project.[3] The Prescription's fish passage conditions, required by Ordering Paragraph (E), are attached as Appendix B to the License.

Section 12.2.2 of the Prescription states, "The Licensee shall operate the Project to exceed the minimum downstream survival efficiency criterion of 76 percent of the adult (i.e., silver) American eel moving downstream past the Project." This survival efficiency criterion is based upon the Sweka et al. (2014) American eel egg-per-recruit (EPR) model (Model)[4] which indicates that cumulative silver eel survival passing three to four dams must exceed a minimum of 76 percent at each dam and must be higher to rebuild the American eel population. However, the Service recently received information that the referenced model does not apply to the

[1] Accession No. 20170523-5083.
[2] Accession No. 20180627-5030.
[3] 174 FERC ¶ 62,135
[4] Sweka, J. A., Eyler, S., and Millard, M. J. 2014. An egg-per-recruit model to evaluate the effects of upstream transport and downstream passage mortality of American eel in the Susquehanna River. *North American Journal of Fisheries Management*, 34:764-773.

Penobscot River, for the reasons described by the model's developer in the attached memo (Attachment A).

Therefore, the Service is notifying the Commission that the Model was parameterized specifically for the Susquehanna River and model results cannot be directly applied to the development of passage standards at any facilities outside of the Susquehanna River watershed.[5]

If you have any questions, please contact Julianne Rosset of this office at julianne_rosset@fws.gov.

RE: Application of the Sweka et al. (2014) American eel EPR model to the Penobscot River

Dear Ms. Rosset,

The use of the Sweka et al. (2014) American eel egg-per-recruit (EPR) model to prescribe a minimum downstream passage survival for eels of 76 percent at Mattaceunk Hydroelectric Project (FERC No. 2520) on the Penobscot River represents a misuse of model results.

The model was designed to determine a level of downstream survival for American eels to ensure that the overall reproductive potential for eels emigrating from the Susquehanna River would not be reduced during silver eel migration if eels were passed upstream of hydroelectric projects. The published model was specific to the situation on the Susquehanna River in which American eels are captured at the first dam on the river (Conowingo Dam, P-405) and trucked upstream of the other four hydroelectric projects: Muddy Run Pumped Storage Station (P-2355), Holtwood Dam (P-1881), Safe Harbor Dam (P-1025), and York Haven Dam(P-1888). The model assumed that any migrating silver eels originated from either below Conowingo or above York Haven Dam, and no eels matured to the silver stage between dams. Because American eels have been precluded from passing above the four mainstem dams on the Susquehanna River for many decades, contemporary life history parameters for American eels in the Susquehanna do not exist and the model was largely theoretical in nature and borrowed life history parameters documented in scientific literature from other river systems. Given the life history parameters used and spatial structure of the hydroelectric projects on the Susquehanna River, Sweka et al. (2014) determined a "break-even threshold" cumulative downstream passage survival of 33 percent was needed. At this level, passing eels upstream resulted in the same EPR as not passing eels upstream of Conowingo Dam. Higher cumulative downstream passage survival would result in a higher EPR. The 33 percent "break-even threshold" is specific to the Susquehanna River and the life history parameters used in the modeling of that situation and should be considered a minimum level to ensure additional harm to the population is avoided. Something greater than the "break-even threshold" is needed to increase the population.

In the discussion section of the Sweka et al. (2014) paper (page 771), the authors describe the sensitivity of model results to the input parameters and the effect these input parameters would have on the "break-even threshold." Differences in growth, natural mortality, and the proportions of eels that become female in river reaches above dams compared to reaches below dams will have a large effect on the location of the "break-even threshold". Appropriate application of this model to other systems requires updating the life history parameters to be

specific to the river system in question because of their large effect on model results.

As stated by Sweka et al. (2014), "If emigrating American eels are required to pass more hydroelectric facilities, the downstream passage survival at each hydroelectric facility will need to increase in order to realize any reproductive benefit from upstream passage or transport." The Susquehanna River was very simple to model with only five hydroelectric projects in succession and those projects in relatively close proximity on the lower mainstem of the river. However, the spatial structure of the Penobscot River is more complicated with more hydroelectric dams in the watershed, the dams spread over larger distances, and the dams located on multiple tributaries within the watershed. Additionally, eels are not trucked from the first dam on the Penobscot, upstream of all of the other dams. This complicated spatial structure would result in different portions of the silver eel population encountering different numbers of dams during migration. Thus, a spatial structure that more accurately reflects the Penobscot River would need to be incorporated into the model before it could be used to make a downstream passage survival criterion at a specific hydroelectric project in that system.

In conclusion, the modeling framework by Sweka et al. (2014) can be useful in determining passage criteria. However, direct application of the "break-even threshold" of 33 percent cumulative downstream passage survival to other river systems represents a misuse of the model. If emigrating silver eels only need to pass four dams, each with 76 percent downstream passage efficiency, and the life history of American eels was the same as that modeled in the Susquehanna River, then the 33 percent cumulative downstream passage target (0.76 x 0.76 x 0.76 x 0.76 = 0.33) would be appropriate. However, there are more than four dams on the Penobscot River through which silver eels need to pass, and life history of American eels in the Penobscot River likely differs from those modeled on the Susquehanna River. Differences between the Susquehanna River and the Penobscot River were not considered when recommending the 76 percent downstream passage target for the Mattaceunk Project. Therefore, use of the 76 percent downstream passage target in for the Mattaceunk Project is not appropriate. The intent of the Sweka et al. (2014) paper was to present a model that could be adapted to other rivers, not to present a downstream passage survival criterion to be used in other rivers. Modification of the model in terms of life history input parameters and spatial structure is necessary when applying the modeling methodology to other rivers.

Sincerely,

John Sweka and Sheila Eyler

FEDERAL ENERGY
REGULATORY COMMISSION

January 4, 2023

**Subject:** **Ripogenus Hydroelectric Project (FERC No. 2572-133)**
**Penobscot Mills Hydroelectric Project (FERC No. 2458-247)**
**Proposed Modification to Relicensing Schedule**

Dear Stakeholder:

Great Lakes Hydro America, LLC (GLHA), Licensee of the Ripogenus Hydroelectric Project (FERC No. 2572) and the Penobscot Mills Hydroelectric Project (FERC No. 2458) (collectively referred to as the "Projects"), is proposing to modify the Projects' relicensing schedule (i.e., revert back to the Projects' original relicensing schedule). The Projects are located on the West Branch of the Penobscot River and Millinocket Stream in Piscataquis and Penobscot counties, Maine.

The current licenses for the Projects were issued on October 22, 1996 and expire on September 30, 2026. On June 11, 2021, GLHA filed the Notices of Intent and Pre-Application Document (PAD), which initiated the formal relicensing proceeding to obtain two separate new licenses for the continued operation of the Projects through the Federal Energy Regulatory Commission's (FERC) Integrated Licensing Process (ILP). In support of the relicensing process and consistent with FERC's ILP schedule, on March 23, 2022, GLHA filed a Revised Study Plan (RSP) for the Projects.

Pursuant to 18 CFR 5.13(c) and consistent with the Projects' process plan and schedule, FERC was to issue the Study Plan Determination within 30 days of the RSP filing (i.e., April 22, 2022) and subsequently, the Initial Study Report (ISR) was to be filed with FERC within 1 year of the Study Plan Determination (i.e., April 22, 2023). However, via letter dated April 7, 2022, the Projects' original relicensing schedule was modified by FERC to accommodate stakeholders' requests for additional time to file comments on the RSP. Therefore, FERC issued the Study Plan Determination for the Projects on May 13, 2022, which indicated that the ISR shall be filed with FERC by May 13, 2023.

Based on this revised ISR filing date of May 13, 2023, the subsequent deadline for additional or modified study requests and potential disputes would not be complete until September 10, 2023. Recognizing the potential implications this schedule could have on GLHA's ability to conduct second year studies in 2023, GLHA proposes to modify the project schedule to file the ISR by April 22, 2023 (i.e., the original process plan and schedule presented in the PAD and FERC's Scoping Document 2) as well as the subsequent due dates as defined by 18 CFR 5.15(c). A summary of the current and proposed (i.e., original) schedule associated with the ISR and subsequent due dates is provided for reference in the table below.

Great Lakes Hydro America, LLC
1024 Central Street
Millinocket, ME 04462
www.brookfieldrenewable.com
Tel: 207.723.4341
Fax: 207.723.3948

| Activity | Responsible Party | Timeframe | Current Due Date | Proposed (Original) Due Date |
|---|---|---|---|---|
| File ISR | Licensee | Within 1 year of 1st Study Plan Determination | May 13, 2023 | April 22, 2023 |
| Conduct ISR Meeting | Licensee | Within 15 days of ISR filing | May 28, 2023 | May 7, 2023 |
| File ISR Meeting Summary | Licensee | Within 15 days of ISR Meeting | June 12, 2023 | May 22, 2023 |
| File comments on ISR, ISR Meeting Summary, and new study requests | Stakeholders | Within 30 days of ISR Meeting Summary filing | July 12, 2023 | June 21, 2023 |
| File response to comments on ISR, ISR Meeting Summary, and new study requests | Licensee | Within 30 days of filing of comments and new study requests | August 11, 2023 | July 21, 2023 |
| Issue 2nd Study Plan Determination (if necessary) | FERC | Within 30 days of filing of response to comments and new study requests | September 10, 2023 | August 20, 2023 |

Whereas FERC's April 7, 2022 modification of the relicensing schedule provided stakeholders with additional time to provide comments on the RSP, we now have the opportunity to follow the original relicensing schedule. GLHA believes that reverting back to the Projects' original relicensing schedule will be beneficial to all the relicensing parties; including providing the ISR and holding the ISR Meeting earlier this Spring.

However, if there are any comments or concerns regarding this request, GLHA asks that you provide written comments via email to Cate Russell at cate.russell@hdrinc.com or via mail to 970 Baxter Blvd, Suite 301, Portland, ME 04103 by January 25, 2023. Subsequently, GLHA will file with FERC a request to revert back to the original ILP schedule along with any comments received.

We appreciate your consideration of this schedule change and look forward to working with you on 2023 relicensing activities.

Sincerely,

Randall Dorman
Licensing Manager

Washington, DC 20426. VIA Electronic Filing

**Reference:** Ripogenus Hydroelectric Project (FERC No. 2572-133)
Penobscot Mills Hydroelectric Project (FERC No. 2458-247)

Subject: Opposition to the Licensee's January 4, 2023 letter Proposing a Modification to the combined Project's Relicensing Schedule.

On January 4, 2023 the Licensee requested that the Initial Study Report, associated reports and meeting (s) deadlines be moved forward by approximately one month. Given the time needed to prepare for the next stages of licensing and other scheduling conflicts, this request places and undo burden on the agencies, FERC and perhaps most importantly, the stakeholders. In a September 17, 2021 filing, the Licensee denied an agency and stakeholder request for a 90-day extension. The Licensee now wishes to further reduce the review period. Any scheduling changes during a process that will produce a 30-year license seems both an unnecessary and an unfair burden on the stakeholders.

Licensing events are intended as a collaborated process. The stakeholders are still waiting to be "collaborated with". I have seen no preliminary or final reports concerning fisheries or aquatic communities. Any sharing of field study information would make the stakeholders feel "they were part of the process". If the Licensee wants the opportunity to perform anticipated studies early in the upcoming field season, releasing fisheries and aquatic communities 2022 data collections as well as studies from other guilds would speed up that process.

For the above reasons, I urge FERC to maintain the schedule shown on Table 3.1-1 of the June 11, 2021 Pre Application Document.

Thank you for the opportunity to comment.

**Subject:** **Ripogenus Hydroelectric Project (FERC No. 2572-133)**
**Penobscot Mills Hydroelectric Project (FERC No. 2458-247)**
**Proposed Modification to Relicensing Schedule**

Dear Secretary Bose:

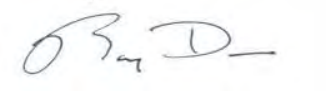
Great Lakes Hydro America, LLC (GLHA), Licensee of the Ripogenus Hydroelectric Project (FERC No. 2572) and the Penobscot Mills Hydroelectric Project (FERC No. 2458) (collectively referred to as the "Projects"), herein files a request to modify the Projects' relicensing schedule. The Projects are located on the West Branch of the Penobscot River and Millinocket Stream in Piscataquis and Penobscot counties, Maine.

The current licenses for the Projects were issued on October 22, 1996 and expire on September 30, 2026. On June 11, 2021, GLHA filed the Notices of Intent and Pre-Application Document (PAD), which initiated the formal relicensing proceeding to obtain two separate new licenses for the continued operation of the Projects through the Federal Energy Regulatory Commission's (FERC) Integrated Licensing Process (ILP). On March 23, 2022, GLHA filed a Revised Study Plan (RSP) for the Projects.

Pursuant to 18 CFR 5.13(c) and as indicated in the Projects' process plan and schedule provided in the PAD, FERC shall issue the Study Plan Determination within 30 days of the RSP filing (i.e., April 22, 2022) and subsequently, the Initial Study Report (ISR) shall be filed with FERC within 1 year of the Study Plan Determination (i.e., April 22, 2023). However, via letter dated April 7, 2022, this schedule was modified by FERC to accommodate stakeholders' requests for additional time to file comments on the RSP. Therefore, FERC issued the Study Plan Determination for the Projects on May 13, 2022, which indicated that the ISR shall be filed with FERC by May 13, 2023.

Based on an ISR filing date of May 13, 2023, the subsequent deadline for additional or modified study requests and potential disputes would not be complete until September 10, 2023. Recognizing the potential implications this schedule could have on GLHA's ability to conduct second year studies in 2023, GLHA proposes to modify the Project schedule to file the ISR by April 22, 2023 (i.e., the original process plan and schedule date provided in the PAD and indicated in FERC's Scoping Document 2) as well as the subsequent due dates as defined by 18 CFR 5.15(c). A summary of the current and proposed (i.e., original) schedule associated with the ISR and subsequent due dates is provided for reference in the following table.

| Activity | Responsible Party | Timeframe | Current Due Date | Proposed (Original) Due Date |
|---|---|---|---|---|
| File ISR | Licensee | Within 1 year of 1st Study Plan Determination | May 13, 2023 | April 22, 2023 |
| Conduct ISR Meeting | Licensee | Within 15 days of ISR filing | May 28, 2023 | May 7, 2023 |
| File ISR Meeting Summary | Licensee | Within 15 days of ISR Meeting | June 12, 2023 | May 22, 2023 |
| File comments on ISR, ISR Meeting Summary, and new study requests | Stakeholders | Within 30 days of ISR Meeting Summary filing | July 12, 2023 | June 21, 2023 |
| File response to comments on ISR, ISR Meeting Summary, and new study requests | Licensee | Within 30 days of filing of comments and new study requests | August 11, 2023 | July 21, 2023 |
| Issue 2nd Study Plan Determination (if necessary) | FERC | Within 30 days of filing of response to comments and new study requests | September 10, 2023 | August 20, 2023 |



Whereas FERC's April 7, 2022 modification of the relicensing schedule provided stakeholders with additional time to provide comments on the RSP, we now have the opportunity to follow the original relicensing schedule. GLHA believes that reverting back to the Projects' original relicensing schedule will be beneficial to all the relicensing parties, including providing the ISR and holding the ISR Meeting earlier this spring.

In support of this request, via letter dated January 4, 2023, GLHA notified all stakeholders on the relicensing distribution list of the proposed modification to the relicensing schedule and requested any comments be provided by January 25, 2023. In addition, a copy of the letter was filed on the Projects' eLibrary dockets.

Via email dated January 20, 2023, the Maine Department of Environmental Protection indicated that the Department had no objection to the proposed schedule. Additionally, on January 18, 2023, Mr. Edward Spear provided FERC with comments on GLHA's request via eComment. Within Mr. Spear's comments is his support for the relicensing schedule outlined in the PAD. No other comments on the proposed schedule were received by GLHA. Copies of the aforementioned correspondence are enclosed.

If you have any questions regarding this letter, please contact me by phone at (207) 775-5605 or by email at randy.dorman@brookfieldrenewable.com.

Sincerely,

Randall Dorman, Licensing Manager

# CORRESPONDENCE RECORD

Brookfield Renewable

January 4, 2023

**Subject:** **Ripogenus Hydroelectric Project (FERC No. 2572-133)**
**Penobscot Mills Hydroelectric Project (FERC No. 2458-247)**
**Proposed Modification to Relicensing Schedule**

Dear Stakeholder:

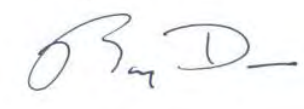
Great Lakes Hydro America, LLC (GLHA), Licensee of the Ripogenus Hydroelectric Project (FERC No. 2572) and the Penobscot Mills Hydroelectric Project (FERC No. 2458) (collectively referred to as the "Projects"), is proposing to modify the Projects' relicensing schedule (i.e., revert back to the Projects' original relicensing schedule). The Projects are located on the West Branch of the Penobscot River and Millinocket Stream in Piscataquis and Penobscot counties, Maine.

The current licenses for the Projects were issued on October 22, 1996 and expire on September 30, 2026. On June 11, 2021, GLHA filed the Notices of Intent and Pre-Application Document (PAD), which initiated the formal relicensing proceeding to obtain two separate new licenses for the continued operation of the Projects through the Federal Energy Regulatory Commission's (FERC) Integrated Licensing Process (ILP). In support of the relicensing process and consistent with FERC's ILP schedule, on March 23, 2022, GLHA filed a Revised Study Plan (RSP) for the Projects.

Pursuant to 18 CFR 5.13(c) and consistent with the Projects' process plan and schedule, FERC was to issue the Study Plan Determination within 30 days of the RSP filing (i.e., April 22, 2022) and subsequently, the Initial Study Report (ISR) was to be filed with FERC within 1 year of the Study Plan Determination (i.e., April 22, 2023). However, via letter dated April 7, 2022, the Projects' original relicensing schedule was modified by FERC to accommodate stakeholders' requests for additional time to file comments on the RSP. Therefore, FERC issued the Study Plan Determination for the Projects on May 13, 2022, which indicated that the ISR shall be filed with FERC by May 13, 2023.

Based on this revised ISR filing date of May 13, 2023, the subsequent deadline for additional or modified study requests and potential disputes would not be complete until September 10, 2023. Recognizing the potential implications this schedule could have on GLHA's ability to conduct second year studies in 2023, GLHA proposes to modify the project schedule to file the ISR by April 22, 2023 (i.e., the original process plan and schedule presented in the PAD and FERC's Scoping Document 2) as well as the subsequent due dates as defined by 18 CFR 5.15(c). A summary of the current and proposed (i.e., original) schedule associated with the ISR and subsequent due dates is provided for reference in the table below.

Great Lakes Hydro America, LLC
1024 Central Street
Millinocket, ME 04462
www.brookfieldrenewable.com
Tel: 207.723.4341
Fax: 207.723.3948



| Activity | Responsible Party | Timeframe | Current Due Date | Proposed (Original) Due Date |
|---|---|---|---|---|
| File ISR | Licensee | Within 1 year of 1st Study Plan Determination | May 13, 2023 | April 22, 2023 |
| Conduct ISR Meeting | Licensee | Within 15 days of ISR filing | May 28, 2023 | May 7, 2023 |
| File ISR Meeting Summary | Licensee | Within 15 days of ISR Meeting | June 12, 2023 | May 22, 2023 |
| File comments on ISR, ISR Meeting Summary, and new study requests | Stakeholders | Within 30 days of ISR Meeting Summary filing | July 12, 2023 | June 21, 2023 |
| File response to comments on ISR, ISR Meeting Summary, and new study requests | Licensee | Within 30 days of filing of comments and new study requests | August 11, 2023 | July 21, 2023 |
| Issue 2nd Study Plan Determination (if necessary) | FERC | Within 30 days of filing of response to comments and new study requests | September 10, 2023 | August 20, 2023 |

Whereas FERC's April 7, 2022 modification of the relicensing schedule provided stakeholders with additional time to provide comments on the RSP, we now have the opportunity to follow the original relicensing schedule. GLHA believes that reverting back to the Projects' original relicensing schedule will be beneficial to all the relicensing parties, including providing the ISR and holding the ISR Meeting earlier this Spring.

However, if there are any comments or concerns regarding this request, GLHA asks that you provide written comments via email to Cate Russell at cate.russell@hdrinc.com or via mail to 970 Baxter Blvd, Suite 301, Portland, ME 04103 by January 25, 2023. Subsequently, GLHA will file with FERC a request to revert back to the original ILP schedule along with any comments received.

We appreciate your consideration of this schedule change and look forward to working with you on 2023 relicensing activities.

Sincerely,

Randall Dorman
Licensing Manager
Brookfield Renewable

Ms. Kimberly D. Bose January 18, 2022
Secretary,
Federal Energy Regulatory Commission
888 First Street NE, Room 1A
Washington, DC 20426. VIA Electronic Filing

**Reference:** Ripogenus Hydroelectric Project (FERC No. 2572-133)
Penobscot Mills Hydroelectric Project (FERC No. 2458-247)

Subject: Opposition to the Licensee's January 4, 2023 letter Proposing a Modification to the combined Project's Relicensing Schedule.

On January 4, 2023 the Licensee requested that the Initial Study Report, associated reports and meeting (s) deadlines be moved forward by approximately one month. Given the time needed to prepare for the next stages of licensing and other scheduling conflicts, this request places and undo burden on the agencies, FERC and perhaps most importantly, the stakeholders. In a September 17, 2021 filing, the Licensee denied an agency and stakeholder request for a 90-day extension. The Licensee now wishes to further reduce the review period. Any scheduling changes during a process that will produce a 30-year license seems both an unnecessary and an unfair burden on the stakeholders.

Licensing events are intended as a collaborated process. The stakeholders are still waiting to be "collaborated with". I have seen no preliminary or final reports concerning fisheries or aquatic communities. Any sharing of field study information would make the stakeholders feel "they were part of the process". If the Licensee wants the opportunity to perform anticipated studies early in the upcoming field season, releasing fisheries and aquatic communities 2022 data collections as well as studies from other guilds would speed up that process.

For the above reasons, I urge FERC to maintain the schedule shown on Table 3.1-1 of the June 11, 2021 Pre Application Document.

Thank you for the opportunity to comment.

**Subject:** Ripogenus & Penobscot Mills Hydroelectric Projects: Relicensing Schedule

**EXTERNAL: This email originated from outside of the State of Maine Mail System. Do not click links or open attachments unless you recognize the sender and know the content is safe.**
Dear Stakeholders –

The Ripogenus Hydroelectric Project (FERC No. 2572) and the Penobscot Mills Hydroelectric Project (FERC No. 2458), located on the West Branch of the Penobscot River in Piscataquis and Penobscot Counties, Maine, are currently licensed with the Federal Energy Regulatory Commission (FERC). On June 11, 2021, the licensee, Great Lakes Hydro America, LLC (GLHA), a subsidiary of Brookfield Renewable, initiated the federal relicensing process with the filing of the Notices of Intent (NOIs) and a Pre-Application Document (PAD) for these facilities.

On behalf of GLHA, attached is a letter describing GLHA's proposal to modify the Projects' relicensing schedule by reverting back to the Projects' original relicensing schedule.

Given that our contact database includes your email address, we are providing a copy of this letter via email, in lieu of a direct mailing. If you would like to receive paper copies of future letters, as compared to emails, please contact Cate Russell with HDR at cate.russell@hdrinc.com or (207) 239-3792.

Sincerely,

Cate Russell

ORDER GRANTING EXTENSION OF TIME FOR RECREATION MONITORING AND REPORTING

(Issued February 16, 2023)

1. On February 3, 2023, Brookfield Renewable (Brookfield) filed a request to extend the due dates to conduct recreation monitoring and file recreation reports for various projects located in Maine.[1]

[1] Brookfield Renewable filed its request on behalf of Brookfield White Pine Hydro, LLC for the Gulf Island-Deer Rips Project No. 2283, Weston Project No. 2325, Wyman Project No. 2329, Williams Project No. 2335, North Gorham Project No. 2519, Skelton Project No. 2527, Cataract Project No. 2528, Bonny Eagle Project No. 2529, and Flagstaff Project No. 2612; Black Bear Hydro Partners, LLC for the Milford Project No. 2534; Brookfield White Pine Hydro LLC, Merimil Limited Partnership, Brassua Hydroelectric Limited Partnership, and Eagle Creek Kennebec Hydro, LLC for the Brassua Project No. 2615; Kennebec Water Power Company for the Moosehead Project No. 2671; Black Bear Hydro Partners, LLC, Black Bear SO, LLC, and Black Bear Development Holdings, LLC for the Stillwater Project No. 2712: and Great Lakes Hydro

2. Each license requires the licensee to monitor recreation use and file a report on a six-year cycle (i.e., monitoring in 2020 and filing a report by April 1, 2021) pursuant to the following license articles: Gulf Island-Deer Rips – Article 411, Weston – Article 406, Wyman – Article 411, Williams – Article 406, North Gorham – Article 407, Skelton – Article 413, Cataract – Article 407, Bonny Eagle – Article 412, Milford – Article 414, Flagstaff – Article 410, Brassua – Article 407, Moosehead – Article 412, Stillwater – Article 411, Penobscot Mills – Article 415, and Ripogenus – Article 411. Commission staff issued previous extensions of time to conduct recreation monitoring and reporting due to concerns that recreation use would not be representative of typical recreation seasons due to impacts associated with the COVID-19 pandemic. On March 3, May 14, and September 28, 2021, the due date to file reports on recreation monitoring was extended to April 1, 2023 for all projects.

3. Brookfield requests a 60-day extension to complete recreation monitoring and to file the recreation reports due to unseasonably warm temperatures and lack of snow impacting winter recreational use activities for the Gulf Island-Deer Rips, Weston, Wyman, Williams, North Gorham, Skelton, Cataract, Bonny Eagle, Milford, Flagstaff, Brassua, Moosehead, and Stillwater projects. Brookfield would continue monitoring through the end of March 2023, with the expectation that colder temperatures and more typical winter conditions would provide a more accurate representation of typical use levels. Brookfield acknowledges that use estimates would not be typical of total recreational use due to the delay of winter conditions, but extending the monitoring period through March 2023, would allow for capturing average daily use and peak use under winter conditions.

4. As part of the relicensing process, Commission staff in the Division of Hydropower Licensing issued a study plan determination on May 13, 2022, requiring an inventory, condition assessment, recreation use estimates, user surveys, and boat launch accessibility evaluation for the Penobscot Mills and Ripogenus projects. Brookfield states the study report for the two projects is consistent with the requirements of license (Articles 415 and 411 respectively) and the report would be filed by April 22, 2023.

5. Brookfield's requests provide adequate justification for the extensions of time to complete recreation monitoring and file the required recreation reports and should be granted. The new due date to file recreation reports for the Penobscot Mills and Ripogenus project is April 22, 2023 and June 1, 2023 for the remaining projects.

The Director orders:

(A) Great Lakes Hydro America, LLC's February 3. 2023 extension of time

---

America, LLC for the Penobscot Mills Project No. 2458 and Ripogenus Project No. 2572.

request to file recreation monitoring reports for the Penobscot Mills Hydroelectric Project No. 2458 and Ripogenus Hydroelectric Project No. 2572 is granted. The new date to file the recreation monitoring reports is April 22, 2023.

(B) Brookfield White Pine Hydro LLC, Black Bear Hydro Partners, LLC, Merimil Limited Partnership, Brassua Hydroelectric Limited Partnership, Eagle Creek Kennebec Hydro, LLC, Kennebec Water Power Company, Black Bear SO, LLC, Black Bear Development Holdings, LLC's February 3, 2023 extension of time request to complete recreation monitoring and file recreation monitoring reports for the Gulf Island-Deer Rips Project No. 2283, Weston Project No. 2325, Wyman Project No. 2329, Williams Project No. 2335, North Gorham Project No. 2519, Skelton Project No. 2527, Cataract Project No. 2528, Bonny Eagle Project No. 2529, Flagstaff Project No. 2612, Milford Project No. 2534, Brassua Project No. 2615, Moosehead Project No. 2671, Stillwater Project No. 2712 is granted. The new due date to file the recreation monitoring reports is June 1, 2023.

(C) This order constitutes final agency action. Any party may file a request for rehearing of this order within 30 days from the date of its issuance, as provided in section 313(a) of the Federal Power Act, 16 U.S.C. § 825*l*, and the Commission's regulations at 18 C.F.R. § 385.713 (2021). The filing of a request for rehearing does not operate as a stay of the effective date of this order, or of any other date specified in this order. The licensee's failure to file a request for rehearing shall constitute acceptance of this order.

Randall Dorman, Licensing Manager, Brookfield Renewable
Great Lakes Hydro America, LLC
1024 Central Street
Millinocket, ME 04462

**Reference: Revised Process Plan and Schedule**

Dear Mr. Dorman:

On January 27, 2023, Great Lakes Hydro America, LLC (GLHA) filed a request to modify the Process Plan and Schedule for relicensing the Ripogenus (P-2572) and Penobscot Mills (P-2458) Projects (collectively, the Projects). The current schedule includes a deadline of May 13, 2023,[1] for filing the Initial Study Report (ISR). Based on this ISR filing date, the deadline for issuing a Study Plan Modification Determination is September 10, 2023. GLHA states that filing the ISR this late in the year could limit GLHA's ability to conduct any required second year studies in 2023. Therefore, GLHA requests to file the ISR by April 22, 2023.

GLHA's January 27, 2023, filing provides documentation that stakeholders were notified of GLHA's proposal to modify the relicensing schedule. In response to the notification from GLHA, on January 20, 2023, the Maine Department of Environmental Protection responded via email, which is included with GLHA's January 27 filing, indicating that it had no objection to the proposed schedule change. On January 18, 2023, Mr. Edward Spear filed a letter objecting to the proposed schedule modification.

[1] On April 7, 2022, the Commission modified the original Process Plan and Schedule for relicensing activities under the Integrated Licensing Process to accommodate stakeholder requests for additional time to file comments on the Revised Study Plan. Granting this modification moved the deadline for the Study Plan Determination from April 22, 2022, to May 13, 2022.

Mr. Spear states that, given the lack of collaboration in the process, the time needed to prepare for the next stage of relicensing, and scheduling conflicts, the request to modify the schedule places an undue burden on the agencies, Commission staff, and other stakeholders. However, in that letter Mr. Spear also expresses support for, and urged the Commission to maintain, the schedule proposed in the Preliminary Application Document, which is the schedule now proposed by GLHA. No other entity commented on GLHA's proposed schedule modification.

GLHA's proposed modification to the schedule would result in no reduction in stakeholder opportunity for review and comment on the ISR. In addition, the ISR would be filed by GLHA within 1 year of the Commission's approval of the study plan, as required by section 5.15(c) of the Commission's regulations. Modifying the schedule would add a small amount (about 3 weeks) of time to the 2023 study season, particularly following the ISR study modification determination. Though the amount of additional field time would be small, the time would fall in the period from late August through early September, which could provide an opportunity for carrying out studies that require low flow conditions. Therefore, the relicensing schedule for the Projects is modified as follows:

- The ISR is now due by April 22, 2023.
- The ISR meeting must occur by May 7, 2023.
- The ISR meeting summary is now due by May 22, 2023.
- Comments on the ISR, ISR meeting summary, and new study requests are now due by June 21, 2023.
- Response to ISR comments are now due by July 21, 2023.
- Issuance of a Study Plan Modification Determination (if necessary) is now due by August 20, 2023.

If you have questions regarding this matter, you may contact Allan Creamer at (202) 502-8365, or allan.creamer@ferc.gov.

Sincerely,

VINCENT YEARICK

**Subject: Clarification of Request for Extension of Time to File Recreation Monitoring Reports for the Penobscot Mills (FERC No. 2458) and Ripogenus (FERC No. 2572) Projects**

Dear Secretary Bose,

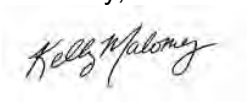
Great Lakes Hydro America, LLC (GLHA), licensee for the Penobscot Mills (FERC No. 2458) and Ripogenus (FERC No. 2572) Projects on the West Branch of the Penobscot River in Maine, respectfully requests a 90-day extension of time (to July 21, 2023) to file documentation of consultation for recreation monitoring reports in order to align with the relicensing schedule.

Article 415 of the Penobscot Mills Project license and Article 411 of the Ripogenus Project license both require a recreation monitoring report, developed in consultation with resource agencies, to be filed every six years to include annual use figures, a discussion of recreation facility adequacy, a description of monitoring methodology, plans for improvement, and documentation of agency consultation. Specifically, both Articles require:

- Documentation of agency consultation and agency comments on the report after it has been prepared and provided to the agencies.
- Specific descriptions of how the agency comments are accommodated by the report.
- A minimum of 30 days for the agencies to comment and to make recommendations prior to filing the report with the Commission.

Both Projects are currently in relicensing, and by letter dated May 13, 2022, the Commission issued its Study Plan Determination for the Projects including a Recreation Study and Whitewater Boating Assessment. The Recreation Study includes an inventory and condition assessment, recreation use estimates, user surveys including recommendations for improvement, and a boat launch accessibility evaluation under various drawdown scenarios. The information being collected is consistent with the requirements of Articles 415 and 411, and, by letter dated February 16, 2023[1], the Commission granted a request filed by GLHA (on

[1] Per FERC Orders dated March 3, 2021 (https://elibrary.ferc.gov/eLibrary/filedownload?fileid=020C072F-66E2-5005-8110-C31FAFC91712) and February 16, 2023 https://elibrary.ferc.gov/eLibrary/filedownload?fileid=AE99011E-ABCF-C405-8F9C-865A5B900001 the current deadline to file these recreation monitoring reports is April 22, 2023.



February 3, 2023) to align the reporting requirements under Articles 415 and 411 with the relicensing schedule.

Further clarification of this request, however, is warranted. Specifically, while GLHA's request noted (and the Commission's extension of time approval confirmed) that the Initial Study Report for the Projects would be filed by April 22, 2023, this would not include the required agency review period. Under the current relicensing schedule approved by the Commission by letter dated February 17, 2023, the Initial Study Report meeting for the Projects will be scheduled for not later than May 7, 2023, with the response to agency and stakeholder comments on the Initial Study Report due by July 21, 2023. As such, while the recreation reporting requirements of Articles 415 and 411 will be satisfied by the filing of the Initial Study Report by April 22, 2023, the agency review requirements of Article 415 and 411 would not.

GLHA is therefore clarifying and requesting an amendment to its previous request for an extension of time to July 21, 2023, to file the documentation of agency consultation and description of how agency comments on the Recreation Study are addressed, coinciding with the filing of the Response to Initial Study Report comments pursuant to the Projects' FERC-approved relicensing schedule.

If you have any questions, please contact Allison Frechette at (207) 755-5602 or allison.frechette@brookfieldrenewable.com.

Sincerely,

Kelly Maloney

**Subject: Response to** Great Lakes Hydro America' s **Request for Extension of Time to File Recreation Monitoring Reports for the Penobscot Mills (FERC No. 2458) and Ripogenus (FERC No. 2572) Projects**

Dear Secretary Bose,

Great Lakes Hydro America, LLC 's (GLHA) March 28, 2023 request for a " me extension for the Recrea" onal Monitoring Reports (Ar" cles 415 and 411 respec" vely) is unwarranted and places an undue burden on the agencies and stakeholders. The Licensee correctly referenced the ongoing licensing(s), and recrea" onal informa" on needs to be made available to par" es interested in these procedures for review, sooner rather than later. The Licensee is a# emp" ng a legal argument against prior scheduling. The Licensee has not made a case as to why this informa" on should be withheld during the forthcoming development of study plans.

While the request to delay Ar" cles 415 and 411 reports has major impacts on boaters, camp owners, campers, and sight-seers' groups; this request also has impacts on agency and stakeholder groups concerned with anglers and angling. Anglers need to be given equal consideraon. T o date, the Licensee has ignored all requests for recreaonal angler surveys.

My interests in these licensing proceedings include fish, aqua" c communi" es, and anglers. Anglers are a major component of the Penobscot Mills and Ripogenus Projects recrea" onal community and the Licensee con" nues to ignore this group. I have seen the recrea" onal survey forms and am appalled by the limited design for the collec" on of angler informaon e.g., use, effort, catch, etc. These data are rounely used to evaluate fisheries and provide insight into the status of (recrea" onal) angler use of the project impoundments and riverine reaches. GLHA con" nues to avoid any meaningful collec" on of angler use and catch data from the projects' impoundments and riverine reaches. Fisheries data are also used in determining water quality standards, e.g., designated uses, an" -degrada" on standards.

My hope is that the **Recreation Monitoring Reports will provide some insight into recreational angler use of project waters. I am not optimistic. Absent useful angler**

**information, the resource agencies and stakeholders will not be able to suggest studies to fill the many data voids. The Recreation Monitoring Reports needs to be available on schedule rather than become part of the Licensee's continuing strategy of withholding information whenever possible.**

**For the reasons stated above, I object to the GLHA's request for a Recreation Monitoring Report(s) time extension. I urge FERC to remain on schedule and make Recreation Monitoring Reports available as scheduled and in a timely manner.**

**Thank you for the opportunity to comment.**

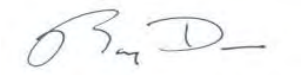
**Subject:** **Ripogenus Hydroelectric Project (FERC No. 2572-133)**
**Penobscot Mills Hydroelectric Project (FERC No. 2458-247)**
**Advance Courtesy Notice of Initial Study Report Meeting**

Dear Secretary Bose:



Great Lakes Hydro America, LLC (GLHA), Licensee of the Ripogenus Hydroelectric Project (No. 2572) and the Penobscot Mills Hydroelectric Project (No. 2458) (collectively referred to as the "Projects"), herein files an advance courtesy notification of the dates and location for the upcoming Initial Study Report (ISR) Meeting.

Consistent with the Federal Energy Regulatory Commission's Integrated Licensing Process (ILP), GLHA will be filing and distributing the ISR by April 22, 2023, and conducting the ISR Meeting within 15 days of filing the ISR (before May 7, 2023). GLHA is required in the ISR to provide details regarding the ISR Meeting. However, given that the ISR Meeting will be an ***in-person*** meeting, as compared to a virtual meeting, GLHA is providing an advance courtesy notification of the meeting dates and location.

Given the number of studies to be presented during the ISR Meeting, the meeting will be held over three days, on May 2, 3, and 4, 2023. The meeting will start at each day at 9:00 AM and is anticipated to end each day at 5:00 PM. The meeting will be held ***in-person*** at the Northern Timber Cruisers, Millinocket Snowmobile Club, located at 10 Northern Cruise Trail in Millinocket, Maine 04462. The agenda for the ISR Meeting and an RSVP request will be included in the ISR.

If you have any questions regarding this advance courtesy notification, the ISR, or the ISR Meeting, please contact me by phone at (207) 775-5605 or by email at randy.dorman@brookfieldrenewable.com.

Sincerely,

Randall Dorman, Licensing Manager

UNITED STATES OF AMERICA
FEDERAL ENERGY REGULATORY COMMISSION

Great Lakes Hydro America, LLC — Project Nos. 2572-133 and 2458-247

# NOTICE OF ENVIRONMENTAL SITE REVIEW

(April 17, 2023)

The Federal Energy Regulatory Commission and Great Lakes Hydro America, LLC will conduct, in conjunction with the Initial Study Report meeting(s), an environmental site review of the Ripogenus and Penobscot Mills Projects. The projects are located on the West Branch of the Penobscot River and Millinocket Stream, in Piscataquis and Penobscot Counties, Maine. The site review will focus on Ripogenus Dam and McKay Station, Millinocket Lake Pump Station, and Stone Dam, as well as the West Branch Penobscot River in those areas. As time permits, other areas that may toured include the Holbrook Side Channel; boat launches, including the Ambajejus Boat Launch; transmission line corridors; Millinocket Gate House; and Millinocket battery bank.

Date and Time: Friday, May 5, 2023; 8:00 a.m. – about 12:00 p.m. (EST)

Location: Meet at the Millinocket Office, 1024 Central St., Millinocket, Maine 04462

The site review is open to the public and resource agencies. All participants interested in attending the site review should provide their own transportation.

Questions about the site review should be directed to Allan Creamer at (202) 502-8365, or allan.creamer@ferc.gov. If you plan to attend, please notify Randy Dorman at (207) 775-5605, or randy.dorman@brookfieldrenewable.com, as well as Allan Creamer, no later than April 28, 2023.

Kimberly D. Bose,
Secretary.

***Via eFiling***

Kimberly D. Bose, Secretary
Federal Energy Regulatory Commission
888 First Street, NE
Washington, DC 20426

**Subject:** **Ripogenus Hydroelectric Project (FERC No. 2572-133)**
**Penobscot Mills Hydroelectric Project (FERC No. 2458-247)**
**Initial Study Report**

Dear Secretary Bose:

Great Lakes Hydro America, LLC (GLHA), the Licensee of the Ripogenus Hydroelectric Project (No. 2572) and the Penobscot Mills Hydroelectric Project (No. 2458) (collectively referred to as the "Projects"), herein files with the Federal Energy Regulatory Commission (FERC) the Initial Study Report (ISR) for the relicensing of the Projects. The Projects are located on the West Branch Penobscot River and Millinocket Stream in Piscataquis and Penobscot counties, Maine.

On June 11, 2021, GLHA filed the Notices of Intent and a Pre-Application Document (PAD), which initiated the formal relicensing proceeding to obtain two separate new licenses for the continued operation of the Projects through FERC's Integrated Licensing Process (ILP). On March 23, 2022, GLHA filed the Revised Study Plan (RSP) and on May 13, 2022, FERC issued the Study Plan Determination (SPD).

Pursuant to the RSP, and as approved and modified by FERC's SPD, GLHA performed study activities in 2022 and early 2023. Pursuant to 18 CFR §5.15(c), GLHA herein files the ISR describing the overall progress in implementing the study plan, presenting the available study results, and describing variances from the approved plan.

FERC's regulations required that GLHA hold a meeting with relicensing participants within 15 days of the due date for the ISR filing (i.e., by May 7, 2023). Given the number of studies to be presented during the ISR Meeting, the meeting will be held over three days, on May 2, 3, and 4, 2023. The meeting will start each day at 9:00 AM and is anticipated to end each day at 5:00 PM. The meeting will be held ***in-person*** at the **Northern Timber Cruisers, Millinocket Snowmobile Club, located at 10 Northern Cruise Trail in Millinocket, Maine 04462**.

In order to plan accordingly, GLHA respectfully requests agencies or stakeholders who plan on attending the meeting RSVP by contacting Cate Russell at Cate.Russell@hdrinc.com or (207) 239-3792 on or before April 28, 2023.

**GREAT LAKES HYDRO AMERICA, LLC**
1024 Central Street, Millinocket, ME 04462
T +1 207.723.4341 F +1 207.723.4597 brookfieldrenewableUS.com

The agenda for the ISR Meeting is included within the ISR and is provided below.

| Date/Time | ISR Meeting Agenda |
|---|---|
| **Tuesday, May 2, 2023** | |
| Morning (9:00 – 12:00) | Welcome, Safety, Ground Rules, Introductions, Relicensing Schedule |
| | Project Overview |
| | Historic Operations Data Assessment Study |
| | Operations Model Study |
| 12:00 – 1:00 | Lunch break (on your own) |
| Afternoon (1:00 – 5:00) | Water Quality Study |
| | Fish Assemblage Study |
| | Fish Stranding Study |
| **Wednesday, May 3, 2023** | |
| Morning (9:00 – 12:00) | Welcome, Safety, Ground Rules, Introductions, Relicensing Schedule |
| | Project Overview |
| | Instream Flow and Habitat Assessment below Stone Dam |
| | North Twin Tributary Access Assessment Study |
| | Upstream Eel Passage Study |
| 12:00 – 1:00 | Lunch break (on your own) |
| Afternoon (1:00 – 5:00) | Downstream Eel Passage Study |
| | Terrestrial, Botanical, and Wildlife Assessment Study |
| | Riparian and Littoral Habitat Assessment Study |
| | Loon Management Plan Assessment Study |
| | Marsh Bird Study |
| | Wood Turtle Study |
| | Furbearer Study |
| **Thursday, May 4, 2023** | |
| Morning (9:00 – 11:30) | Welcome, Safety, Ground Rules, Introductions, Relicensing Schedule |
| | Project Overview |
| | Recreation Study |
| | Whitewater Boating Study |
| 11:30 – 12:30 | Lunch break (on your own) |
| Afternoon (12:30 – 3:00) | Aesthetic Study |
| | Historic Architecture Study |
| | Environmental Justice Study |

On April 17, 2023, FERC issued notice of an environmental site review of the Ripogenus and Penobscot Mills Projects, to be conducted on Friday, May 5, 2023 from 8:00 a.m. to approximately 12:00 p.m. The site review will focus on Ripogenus Dam and McKay Station, Millinocket Lake Pump Station, and Stone Dam, as well as the West Branch Penobscot River in those areas. As time permits, other areas that may be toured include the Holbrook Side Channel; boat launches, including the Ambajejus Boat Launch; transmission line corridors; Millinocket Gate House; and Millinocket battery bank.

**GREAT LAKES HYDRO AMERICA, LLC**
1024 Central Street, Millinocket, ME 04462
T +1 207.723.4341 F +1 207.723.4597 brookfieldrenewableUS.com

The site review is open to the public and resource agencies. Interested parties should notify Randall Dorman via the contact information below. All participants should provide their own transportation and meet at 8:00 am at the Brookfield Renewable Millinocket Office located at 1024 Central St., Millinocket, Maine 04462.

Concurrent with this filing, GLHA is providing a copy of this letter to all parties listed in the attached distribution list. Parties can download an electric copy of the public portions of the ISR from FERC's eLibrary system at https://www.ferc.gov/ferc-online/elibrary by conducting a search using the docket numbers P-2458 and/or P-2572.

Considering that the ISR provides a detailed description of the overall progress of the required studies, a separate Study Progress Report will not be filed on May 1, 2023, as the information would be duplicative of this filing. Pursuant to the ILP schedule, GLHA will file the next Study Progress Report with FERC on or about August 1, 2023.

If you have any questions regarding this letter, the ISR, or the ISR Meeting, please contact me by phone at (207) 775-5605 or by email at randy.dorman@brookfieldrenewable.com.

Sincerely,

Randall Dorman, Licensing Manager
Brookfield Renewable

Washington, DC 20426

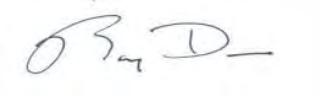
**Subject:** **Ripogenus Hydroelectric Project (FERC No. 2572-133)**
**Penobscot Mills Hydroelectric Project (FERC No. 2458-247)**
**Initial Study Report Meeting Summary**

Dear Secretary Bose:

Great Lakes Hydro America, LLC (GLHA), the Licensee of the Ripogenus Hydroelectric Project (No. 2572) and the Penobscot Mills Hydroelectric Project (No. 2458) (collectively referred to as the "Projects"), herein files with the Federal Energy Regulatory Commission (FERC) the Initial Study Report (ISR) Meeting Summary for the relicensing of the Projects. The Projects are located on the West Branch Penobscot River and Millinocket Stream in Piscataquis and Penobscot counties, Maine.

On June 11, 2021, GLHA filed the Notices of Intent and a Pre-Application Document (PAD), which initiated the formal relicensing proceeding to obtain two separate new licenses for the continued operation of the Projects through FERC's Integrated Licensing Process (ILP). On March 23, 2022, GLHA filed the Revised Study Plan (RSP) and on May 13, 2022, FERC issued the Study Plan Determination (SPD).

Pursuant to the RSP, and as modified and approved by FERC's SPD, GLHA performed study activities in 2022 and early 2023. Pursuant to 18 CFR §5.15(c), on April 22, 2023, GLHA filed the ISR describing the overall progress in implementing the study plan, presenting the available study results, and describing variances from the approved plan. Subsequent to filing of the ISR, GLHA held the ISR Meeting with FERC staff and other relicensing participants on May 2, 3, and 4, 2023 in Millinocket, Maine. Pursuant to 18 CFR §5.15(c)(3) and the schedule provided in FERC's Scoping Document 2, GLHA is filing the enclosed ISR Meeting Summary.



GLHA is also filing hourly operations data from 2000 through 2022 in MS Excel format for each development of the Projects.

Concurrent with this filing, GLHA is providing a copy of this letter to all parties listed in the attached distribution list. Parties can download an electric copy of the public portions of the ISR Meeting Summary from FERC's eLibrary system at https://www.ferc.gov/ferc-online/elibrary by conducting a search using the docket numbers P-2458 and/or P-2572.

**RE: Request for Extension of Time to Comment on Great Lakes Hydro America, LLC (GLHA) Initial Study Report for the Ripogenus Hydroelectric Project (FERC No. 2572) and Penobscot Mills Hydroelectric Project (FERC No. 2458)**

Dear Secretary Bose:

On April 24, 2023, Great Lakes Hydro America, LLC (GLHA) filed the Initial Study Report (ISR) for the Ripogenus (P-2572) and Penobscot Mills Projects (P-2458) located on the West Branch of the Penobscot River in Maine. However, the Licensee did not file electronic hourly flow data for each project as part of the ISR despite repeated requests by FERC and multiple stakeholders since the relicensing commenced in 2021. On October 8, 2021, your staff specifically requested GLHA to submit hourly operations data for the Ripogenus and Penobscot Mills Projects as part of an Additional Information Request for the projects as below. GLHA ignored this request as well.

> FERC October 8, 2021 AIR Schedule A
>
> Detailed operations data is needed to clarify how the projects are operated on a daily basis. Therefore, please include, as an appendix to the Proposed Study Plan, 10 years of operations data (in excel format) for each project, or each individual development, in the case of the Penobscot Mills Project, including: (1) daily impoundment elevations; and (2) daily outflows (minimum, maximum, and average discharges). The data for each project/development should be presented in separate tabs of the excel spreadsheet.

On May 22, 2023, GLHA filed the electronic hourly flow data with the Commission. By purposely delaying the submission of this data from April 24, 2023 (or more accurately, from October 8, 2021) to May 22, 2023, GLHA has significantly curtailed our ability to review and analyze this data which is fundamental for informing our comments including additional study requests. The electronic operations data submitted on May 22 for the Ripogenus and Penobscot Mills Project contains over one million lines of data. It is entirely unreasonable for GLHA to expect us to review it in thirty days. Therefore, we request that FERC issue a minimum 30-day extension of time to file comments on the ISR. The new date to file comments on the ISR would then be July 21, 2023, at the earliest.

We appreciate you consideration of this request. If you have any questions or need additional information, please contact Dan Kircheis (Dan.Kircheis@noaa.gov) or 207-866-7320.

Sincerely,

Julie Crocker
Chief, ESA Fish, Energy, and Ecosystems Branch
Protected Resources Division

Kimberly D. Bose, Secretary June 2, 2023
Federal Energy Regulatory Commission
888 First Street, NE
Washington, DC 20426

Dear Secretary Bose, Via Electronic filing

**Subject: Response to** Great Lakes Hydro America' s Inii al Study Report **Filing of April 22, 2023, Appendix L of the initial Study Report,** Loon Management Plan Assessment Study April 24, 20

After reviewing the above referenced common loon study, I found no reference to surveys of the West Branch of the Penobscot River (West Branch) below McKay Station. This reach is part of the Project area but apparently not part of the loon survey area. This oversight ignores critical loon habitat and the impact of peaking operation on nesting success in the West Branch.

The case in point is a pair of loons that appear to be currently nesting in Nesowadnehunk Deadwater, an occurrence I have witnessed for the last ten years. Based on loon sightings, the nest location appears to be on a grassy island a few hundred feet from the Golden Road causeway, another possibility is "Eagle Island' on the North side of the river.

While the presence of Loons in Nesowadnehunk Deadwater is common knowledge to campers and anglers, other deadwater areas offer similar habitats. Frozen Ocean and Debsconeag Deadwater are large areas with a variety of depths and flows. There are other possible areas which should be cataloged and surveyed to determine the impact of the current McKay Station peaking regime on loon nesting success. The Licensee should include the West Branch reaches below McKay Station in all future loon surveys and evaluate the impacts of up and down peaking flows on nesting success.

Thank you for the opportunity to comment

Washington, DC 20426

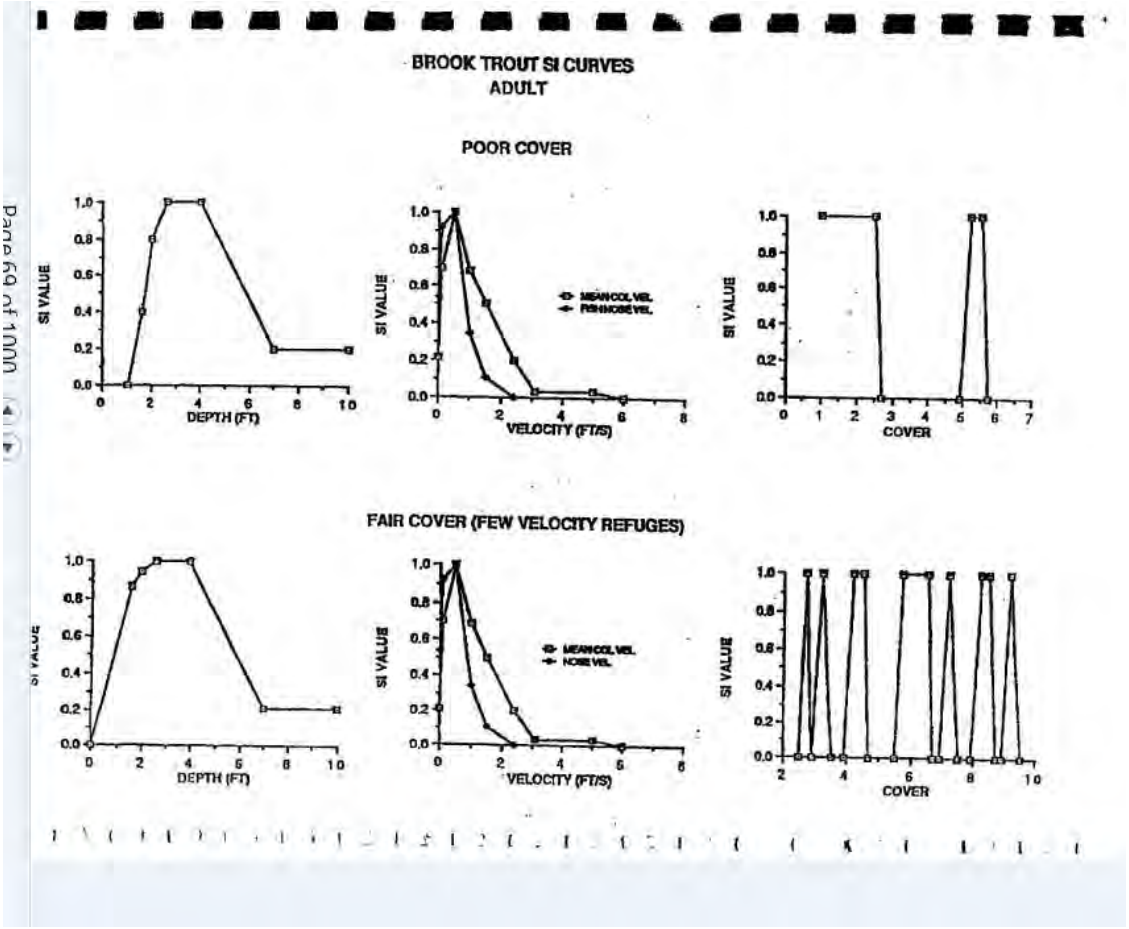
June 2, 2023

Via Electronic filing

Dear Secretary Bose,

**Subject: Response to** Great Lakes Hydro America' s Initial Study Report **Filing of April 22, 2023, Appendix F of the initial Study Report,** Instream Flow and Habitat Assessment of West Branch Downstream of Stone Dam Study**, Penobscot Mills Project (FERC No. 2458)**

The Licensee is seeking to reduce soon to be mandated flows into the historic West Branch Channel below Stone Diversion Dam. In doing so the Licensee essentially duplicated a Great Northern Paper (GNP) 1989 study (conducted by Normandeau Associates Inc.) while developing "new" adult brook trout (trout) Habitat Suitability Rating Criteria (HSC) more favorable to their low flow goal. The Instream Flow and Habitat Assessment of West Branch Downstream of Stone Dam Study is based on unrealistic goals and stretches to the extreme Brook Trout biology and angler behavior. Appendix F uses subjective trout HSC, and fails to include informative reports from GNP creel surveys (circa 1997/98) of contiguous Millinocket Stream, a prime indicator stream. The report also fails to discuss fishing opportunities and cites spill and flow events without including detailed archival flow data in useable format. Absent corrected and peer reviewed adult trout HSC depth requirements, the Appendix F study report fails to provide any new and useful information to the agencies, stakeholders or FERC staff.



Adult trout habitat:

Adult brook trout are often found in one foot of water in mountain streams, small meadows and forested brooks. In 25 years of electrofishing sampling of the West Branch of the Penobscot River (WB) drainage, I never found adult trout in shallow water with open areas. During study years (1978-2020), we had the occasion to electrofish Caucomgomoc and Nesowadnehunk streams, the North and South Branches of the Penobscot River, and finally the WB. While adult trout were collecting in varying quantities, these habitat were always deeper with overhead

and/or significant instream cover. The proposed habitat suitability rating curves for trout need to be revisited and empirical or peer reviewed literature needs to be provided for the decision making process

The HSC for adult brook trout used in Appendix F are unsuitable for a large, wide riverine section such as the dewatered West Branch channel below Stone Dam. I was unable to locate peer reviewed publications, interim reports or summary data sheets that suggest water depth less than two feet is suitable for adult trout in a wide (200 ft), open (no overhead cover), shallow (two feet or less in depth) river reach.

The only appropriate local, Maine developed adult habitat suitability curve I found was developed and used in the Dead River (Flagstaff Storage Project P2615). In 1994 Kleinschmidt associates, members of the Licensee's current West Branch Channel study team, used the adult trout suitability indexes shown below in the Dead River licensing event. The omission of these HSC data is a mystery as both the historic West Branch Channel and Dead River are wide reaches that lack overhead cover. The Dead River HCS would seem ideally suited for the West Branch Channel instream flow study and should have been used.

Flows into the historic West Branch channel are a critical component in the ongoing licensing process. Subjective judgement should not be used to develop adult trout HSC. Available habitats at various flows will become the base for making decisions in requiring Stone Dam flows in the historic West Branch Channel for the next 30-40 years. Dead River HSC should be inserted into the habitat-flow model.

The Practicality and availability of trout for stocking. Article 413 of the current Penobscot Mills Project ordered then Great Northern Paper to upgrade historic Millinocket stream stocking of Brook Trout.

> *Article 413. The Licensee shall implement an upgraded spring and fall brook trout stocking program to provide a seasonal fishery in Millinocket Stream. Each stocking shall consist of about 500 fish ranging in size from 1/3 to one pound and shall be distributed among five locations approved by the Maine Department of Inland Fisheries and Wildlife (DIFW).*

**Duplication of Article 413 of the Penobscot Mills Project appears to be the licensee's West Branch Channel goal. A review of MeDIFW's Historical stocking Reports during the 2010 – 2022 period suggest that easily accessible Millinocket Stream stockings were not in accordance to Article 413, a likely License violation. While the authors of Appendix F state that April is a begin date, April stockings have occurred only once (2021). Maine Department of Inland Fisheries and Wildlife stocking records dating back to 2010 provided even more damming evidence. April -June stocking of catchable trout that met Article 413 guidelines only occurred twice (2021, 2022). Fall stocking at a time when fishing interest has waned, occurred regularly. For unknown reason, there were several occasions where one to two inch fry were stocked in May (see the below example) to further violate the license article.**

**Maine Department of Fisheries and Wildlife 2016 Stocking Report**

Fishing opportunity; . A spot, or place to fish along with the presence of fish is called "fishing opportunity". It is one thing to state that fish will be stocked (trout) but this filing fails to deal with where and how anglers will locate a place to fish. Appendix F Describes '*mesohabitats upstream of Grand Falls are dominated by riffles and runs with scattered braided channels"* and *"the lower reach is narrower, steeper and has a better-defined channel*", pool areas are noticeably absent from either the narrative or photos (Appendix F-5). Clearly, unlike nearby Millinocket Stream, West Branch channel is void of places anglers would select as a place to fish. The report needs to be corrected and include pools and deep runs associated with anglers fishing for stocked trout in such as places like nearby Millinocket stream. The Licensee's present plan follows a "field of dreams" fantasy.

Season: The duration of a stocked trout fishery: Appendix F speaks of season in terms of the duration of a stocked trout fishery. "It *is expected that these fish would be stocked in April and available for angling harvest from April until mid-summer*" (Appendix P 13). As the Licensee is fully aware, this statement is absurd. Circa 1997 and 1998, GNP conducted season long (May – September) creel surveys of Millinocket Stream. Meaningful May angler use and success lasted approximately one week. Reports of these surveys should be in the GNP's

archives and possibly in MeDIFW files. These reports need to be included in the revised report. Fish stocked in May, the typical period of put-and-take trout stocking, assuming trout would find suitable pools and deep runs to populate and anglers could find a location suitable to fish, the proposed stockings might provide a one-week fishery.

Leakage/Spillage: The Licensee suggests that flow in the Channel is greater than the 3.0 cfs stated in the EIS. "*However, the total amount of leakage occurring at Stone Dam at any given time varies depending on the seasonal impact of flows and ice on the flashboards and short-term wind/wave action. Two more recent measurements of leakage conducted in 2021 found that leakage varied between 17 and 100 cfs".* The connotation is that current flows are environmentally better than previously recorded. The Licensee is a very competent manager of storage and flow, sometimes to the determent of fish and aquatic communities. In this section, we are told that the Licensee routinely allows a 100 cfs of flow to escape energy production. I seriously doubt this.

The Licensee has provided lake elevations from North Twin and Stone Dams and hourly average flows from the North Twin and Mill One facilities that may support the claim of higher leakage. The much needed flow data presented in the Licensee's filing dated May 23, 2023 demonstrates the change in operations to a peaking mode. However, these data are totally inadequate in documenting *higher leakage (flow) claims* as the level of detail needs to be refined into shorter time periods (see Results – Flows from Stone Dam at Millinocket Development (2000-2022)). Alternately, the Licensee using more proficient programming skills, can list the volume and dates that "higher leakage flows" occurred. The burden of proof is the Licensee's. Absent these data, the Licensee should strike these "leakage flow" references from Appendix F.

Appendix F also mentions spill events that result from unseasonable large rain events. Unlike naturally produced landlocked salmon, hatchery reared stocked trout are extremely vulnerable to sudden flow change. The fact that the WB channel area lacks flow refuge i.e. pools and deadwaters, only increases the likelihood that trout would be displaced downstream. Spill events are recorded in archival GNP files. The Licensee should provide 50 years of April, May, and June spill event data.

For the reasons explained above, Appendix F provides data that demonstrates the futility of attempting to create a "put and take" trout fishery. In order to facilitate agency and stakeholder rebuttals as the process moves forward, FERC should

request that the Licensee recalculate adult trout habitat at various flows using Dead River HSC. The Licensee should also provide the requested flow and elevation data in minute detail, provide circa 1997/1998 Millinocket Stream License article 403 mandated creel survey reports, identify potential fishing sites and angler access points in the historic West Branch channel. As presented, Appendix F does not meet the study goal and provides no new useful information.

Thank you for the opportunity to comment

Project Nos. 2572-133 & 2458-247 –
Maine
Ripogenus Hydroelectric Project
Penobscot Mills Hydroelectric Project
Great Lakes Hydro America, LLC

**VIA FERC Service**

**Reference: Extension of Time to File Comments on the Initial Study Report**

To the Parties Addressed:

On April 24, 2023, Great Lakes Hydro America, LLC (GLHA) filed its Initial Study Report (ISR) for the Ripogenus Project (P-2572) and Penobscot Mills Project (P-2458) (collectively, the Projects). Due to the large volume of information filed with the ISR and ISR meeting summary, the ISR comment deadline is extended 15 days to **July 6, 2023**, and the Director's Study Plan Modification Determination deadline is now **September 4, 2023**.[1]

Sincerely,

VINCENT YEARICK

RE: Comments on the Environmental Inspection Report submitted May 2, 2023 for the Ripogenus Hydroelectric Project (FERC No. 2572) from the Caribou and Chesuncook Lake Camp Owners Association and the Chesuncook Dam Camp Owners Association.

Dear Secretary Bose:

On behalf of the members of the Caribou and Chesuncook Lake Camp Owners Association and the Chesuncook Dam Camp Owners Association, I am submitting these comments in response to the Environmental Inspection Report for Ripogenus Project 2572 conducted on August 17, 2022 and submitted May 2, 2023.

The two Associations represent over fifty camp owners with a significant and substantial interest in the operation of this project and its effects on the lakes, and surrounding ecosystems including their fish and wildlife. We have a deep love for, and knowledge of, Caribou, Chesuncook, and Ripogenus Lakes, all natural lakes interconnected and level controlled by Ripogenus Dam. We all have large financial and time commitments to our properties. Many of our members have long multi-generational histories on the lakes and know them well before and after the current licensee.

There are discrepancies between statements in the Initial Study Report presented to stakeholders in May of 2023, and claims made by the licensee in the The Safety Inspection Report, conducted on August 17, 2022. The purpose of this letter is to identify those discrepancies.

The Inspection Report states,

"*The licensee deploys seasonal nesting platforms for loons and other waterfowl every spring. As the inspection occurred in August, representative platforms were inspected in storage. They were found to be adequately maintained and appropriately built for their purpose (photo 3).*

This claim is not substantiated in the Initial Study Report (ISR) Loon Study or by statements from the licensee at the Study Report meeting. The ISR does provide a picture of a loon platform in the water in 2022. As supported by anecdotal evidence of those who spend a considerable amount of time on the water, 2022 is the year evidence of monitoring and maintenance of platforms began again. It is also the year after the Pre Application Document was submitted. The licensee provides no explanation of why platforms were unable to be inspected in the month of August. The ISR explains, *"Due to the size and weight of the nest platforms, platforms remain in place or are towed to the shoreline and are propped up to dry for the off season."* If this is accurate, it would have been possible to inspect platforms on site in August. At the ISR meeting, when asked by Maine Inland Fisheries and Wildlife representatives if loon platforms are left high and dry as drawdowns occur, or carried to shore at the end of the season, a Brookfield

representative replied that unfortunately, yes, the platforms were left wherever they had been deployed, further supporting the ability to conduct on lake inspections in August.

The ISR does provide evidence supporting attainment of Article 409 in the past, *"At the end of the required 10 years of monitoring (2000-2010), GLHA was required to assess whether additional monitoring was required in consultation with the USFWS, MDEP and MDIFW. The MDEP responded that it had no comments on the report and no comments were received from the USFWS or MDIFW. GLHA recommended no additional monitoring or reporting at the Ripogenus Impoundment based on the findings of the 10 years of monitoring data. However, GLHA proposed to continue to deploy artificial nest platforms and increase the number of nests deployed in the Ripogenus impoundment and proposed to periodically check platforms to ensure they were functioning properly. Pursuant to an order issued February 9, 2011, FERC determined that the final report fulfilled the requirement of Article 409 and determined that monitoring was no longer required.*

However, attainment of Article 409 does not equate to the licensee's claims of "deploying seasonal platforms every spring," while providing a picture of a new platform in a storage facility as evidence. In the ISR, the licensee submits, *"Although nest monitoring use/success was discontinued in 2011, GLHA continues to check the nests at least once during the nesting season to evaluate the condition of the platform and make repairs if necessary.* ***Although not documented by GLHA staff since 2010****, GLHA staff responsible for deployment and maintenance have observed use of some of the platforms by nesting loons."* This claim, with no supporting evidence, is very different from the experience of lake users who have observed loon platforms, which have stayed in place for years, unmaintained, never even touching water in low water years.

The Loon Study data from 2000-2010 is dismal. In the 10-year span, eight of the eleven platforms were never utilized by loons. Of the platforms utilized, between 2000 and 2010, seven eggs hatched, two eggs were abandoned, three eggs were gone from nests and one egg was dead. This data does not constitute a successful program. It is unfortunate continued platform deployment and maintenance were not continued regularly, but the licensee was not required to do so. The licensee should be accurate in their portrayal of the lack of loon program from 2010-2021. It is disheartening to see such little effort from the licensee to protect one of Maine's most iconic species.

There is further discrepancy between the Inspection Report and the ISR regarding hydrology and flows. In the Inspection Report, Commission staff cites "*a member of the public alleged that the prior weekend a whitewater release did not occur*. *Licensee flow data was provided to verify adequate flows pursuant to Article 402 occurred*." Flow data provided to stakeholders by the licensee (see below) shows combined station and non-station flows on Sunday, August 14, 2022 ranging from 1540 cfs to 1877 cfs between the hours of 0830-1700. The required rafting flows for that day/time are 2200-2300 cfs depending on the hydrology of the year.

| Date/Time | Flows (cfs) | Non Station Flow | Lake Level |
|---|---|---|---|
| 2022-08-14 08:00:00 | 1440 | 100 | 935.03 |
| 2022-08-14 09:00:00 | 1482 | 100 | 935.04 |
| 2022-08-14 10:00:00 | 1524 | 100 | 935.02 |
| 2022-08-14 11:00:00 | 1566 | 100 | 935.02 |
| 2022-08-14 12:00:00 | 1609 | 100 | 935 |
| 2022-08-14 13:00:00 | 1651 | 100 | 934.99 |
| 2022-08-14 14:00:00 | 1693 | 100 | 934.98 |
| 2022-08-14 15:00:00 | 1735 | 100 | 934.97 |
| 2022-08-14 16:00:00 | 1777 | 100 | 934.96 |

As explained in the Inspection Report, drought is also cited by the licensee as another reason for low flow, *"Due to persistent drought conditions in the area, prior whitewater flows had been more apparent in 2022, because the licensee had to significantly increase flows to meet the requirement."* This statement is in direct conflict with the ISR (see below) which identifies 2022 as a wet-average year. Those using the lakes and rivers were thrilled in 2022 there was finally water after 2021 being exceptionally dry.

| | | | |
|---|---|---|---|
| 2010 | 2,669 | 11 | Average |
| 2014 | 2,690 | 10 | Average |
| 2022 | 2,741 | 9 | Wet-Average |
| 2007 | 2,956 | 8 | Wet-Average |
| 2009 | 2,981 | 7 | Wet-Average |

The Safety Inspection was conducted nearly nine months before the ISR and flow data were released, both containing information that contradicts the Inspection Report. We want to ensure discrepancies are documented so licensing decisions can be made with accurate information.

Thank you for the opportunity to provide comments.

Respectfully,

Bill Houston

Kimberly D. Bose, Secretary June 26, 2023
Federal Energy Regulatory Commission
888 First Street, NE
Washington, DC 20426 Reforma! ed June 30, 2023

Dear Secretary Bose, Via Electronic filing

**Subject: Response to** Great Lakes Hydro America' s **Filing of April 24, 2023, Appendix D of the initial Study Report,** Fish Assemblage Study Report.

The Fish Assemblage Study was conducted at the request of Maine Department of Environmental Protec#on (MDEP) and Trout Unlimited (TU). The study plan, as implemented, is a product of the Licensee. Field collec#ons were imitated in July, 2022.

This filing as with all others of the Licensee, is part of an on-going strategy to whitewash the change in Project opera#on from papermaking produc#on with steady flows and gradual drawdowns to market driven peaking power with highly variable flows and dras#c drawdowns. The Licensee contorts itself to paper over the drama#c impact of this radical shi%on fish and aqua#c communi#es. The Fish Assemblage Ini#al Study Report (ISR) a! empts to create a "record" for future legal arguments rather than provide robust field collec#on results that describe the status of the Ripogenus Project's salmonid and smelt popula#ons(s). The ISR does not accomplish agency and stakeholder goals. The ISR also contains a number of errors and conclusions based on faulty assump#ons. Major omissions are the result of a flawed study design. This filing is intended to correct the record.

<u>The Reasons for Studies</u>

There are both technical and anecdotal reports that indicate the Ripogenus Impoundment and the downstream West Branch of the

Penobscot River (West Branch) are no longer mee#ng fisheries goals. The Maine Department of Inland Fisheries and Wildlife (MeDIFW) creel survey reports demonstrate a decline in the Ripogenus Impoundment salmon growth and low abundance of historical “common” large (>18”) landlocked salmon (salmon). Anecdotal reports indicate that the fish and aqua#c insect communi#es of the West Branch downstream of McKay Sta#on have precipitously declined. Fisheries and aqua#c community informa#on collected in the Big A Applica#on (P2669) and then Ripogenus Project Applica#on process is 35-45 years old and out dated. Especially so because Project opera#ons are now widely fluctua#ng peaking flows and rapid impoundment drawdowns. There is no current quan#ta#ve informa#on on the size of the Ripogenus salmon popula#on e.g. mark recapture es#mates and NO informa#on on the West Branch salmon popula#on downstream of McKay Sta#on rela#ng to abundance, age and growth, spawning and movement in response to peaking flows. Juvenile smelt raised in the Ripogenus Impoundment support both lacustrine and riverine salmonid popula#ons. The abundance and age structure of Ripogenus smelt popula#on(s) is unknown as is the reason(s) for their paucity.

There is no current informa#on on angler use and catch in the riverine areas below North Twin and Dolby Dams or the Millinocket facility. Historically (GNP 1991) these reaches supported salmon fisheries of varying magnitudes. Moreover, access to Millinocket and Dolby facili#es is limited by imposing fencing. To date, no a! empt has been made to define the status or poten#al of these fisheries.

Study Requests and Par#cipants

The MeDEP and TU requested fish assemblage studies. The former to determine if water quality standards were being met; the later for comparison to historical fisheries data (see 1991 Applica#on). These studies were approved and carried out in 2022. The ISR Appendix D was

issued April 22, 2023. Unfortunately, in numerous cases, cri#cal data were misrepresented or in many cases, not collected due to faulty study design or limita#on of sampling gear.

The ISP was caried out by three consul#ng firms: Kleinschmidt Associates, Normandeau Associates and Midwest Biodiversity Institute MBI. Having electrofished and trap ne! ed all the impoundments and riverine reaches surveyed, clearly a great deal of #me and effort was expended. This was an impressive effort with unimpressive results. Collec#vely these survey groups will be referred to as the Licensee. Authorship of the ISR Appendix D is unclear.

General comments

Throughout the study phase of these ongoing licensing processes the Licensee has chosen sampling sites and methods contrary to standard or suggested protocols. The fish assemblage study is no different. With the excep#on of fall sampling near Umbazookus Stream, the Licensee sampled when it wanted and where it wanted. The sampling scheme carefully avoided the “smelt issue” and the abundance, growth and spawning success of West Branch salmon. There were no comparisons between GNP 1991 data and the results of fish assemblage sampling. Many data gaps or voids remain unanswered.

The ISP contains glaring unexplained absences.

- Scale samples were not removed from salmonid species despite a US Fish and Wildlife Service (FWS) request, a normal component of salmonid sampling.
- In the comment period, FERC required Spring sampling and the FWS recommended GLHA add Spring 2023 sampling events (smelt, white and yellow perch and longnose suckers are spring spawners)

- The ISP provides great detail of fish handling protocols, however there is NO men#on as to how the fish were anesthe#zed or how they were held during recovery. It is physically impossible to handle salmonids e.g. weigh, examine for wounds (damaged vertebrates) without quie#ng the fish.
- A! emp#ng to sample pelagic fish e.g., salmon and smelt with shallow water sampling gear e.g., trap nets and boat electrofishing predetermined the lack of meaningful results. Major issues remain unanswered.
- While requested, smelt abundance either by riverine dri%ne' ng or by a variety of lacustrine methods e.g., trawls, ver#cal gill nets, etc. was not undertaken.
- While presented in graphic form for other species, salmon and smelt length distribu#ons were not provided.

The proposed Fish assemblage study included a desktop-based effort to compile, review, and describe exis#ng, contemporary data and anecdotal informa#on collected in the Ripogenus impoundment by the MeDIFW and other organiza#ons. In their April 7, 2022, comments on the RSP, the MDEP reiterated their request for a field-based fish assemblage study for the Ripogenus impoundment. The US Fish and Wildlife Service (FWS) *"recommends GLHA add smelt spawning surveys to all major tributaries to Chesuncook Lake, Caribou Lake, and Ripogenus Lake.*
*FWS recommends GLHA collect scales from all trout, salmon, whitefish, smelt, and togue for age and growth analysis as well as stomach contents for all game species.*

*FWS recommends GLHA compute, and include in the Initial Study Report, the proportional stock densities for all game species.*

- *FWS recommends GLHA conduct Atlantic salmon redd surveys in various reaches of the West Branch, downstream of McKay Station, including in the Little A, and Nesowadnehunk Deadwaters.*
- *Smelt drift nets should be installed weekly from April to November in the West Branch in the Holbrook reach on both sides of the river."*

Juvenile smelt (less than a year old) provide critical salmon forage in the impoundment and West Branch of the Penobscot River (West Branch). Salmon are the fish species that MeDIFW focus its management goals. The lack of information on the spawning success, age structure and abundance of the Ripogenus smelt population is critical in the future decision making process and is a major data gap.

Informa#on gathered in the Office Study

The “office study” included examining exis#ng data available in MeDIFW files and the former Licensee, Great Northern Paper’s (GNP) 1991 License Applica#on. GNP data were based on field collec#on da#ng from 1978 – 1989. Despite the Licensee’s claim that a “vast body” of (1978-1989) informa#on exists, very li! le of material found in the 1991 License Applica#on was included in ISR. The Licensee “cherry picked” MeDIFW informa#on, providing only data that supported the goal of “nothing has changed”, all is well. Informa#on presented as being MeDIFW’s, in several instances was GNP data, and to make ma! ers worse, was incomplete or unsupported with exis#ng tabular data.

From the office study the Licensee states that MeDIFW has a “good understanding” (Appendix D-40) of the Ripogenus Impoundment fish community. “Good understanding” is a term of art, a management posi#on rather than a scien#fic finding. If the Licensee found the necessary MeDIFW reports concerning trap ne' ng, seining, ver#cal gill ne' ng, hydroacous#c, telemetry or even the use of minnow traps, these data should be provided. Absent these data, the stakeholders, agencies and FERC staff will s#ll lack knowledge needed to fill data gaps and argue for the necessary protec#on of fish and aqua#c communi#es. Further studies are required to fill these cri#cal data gaps.

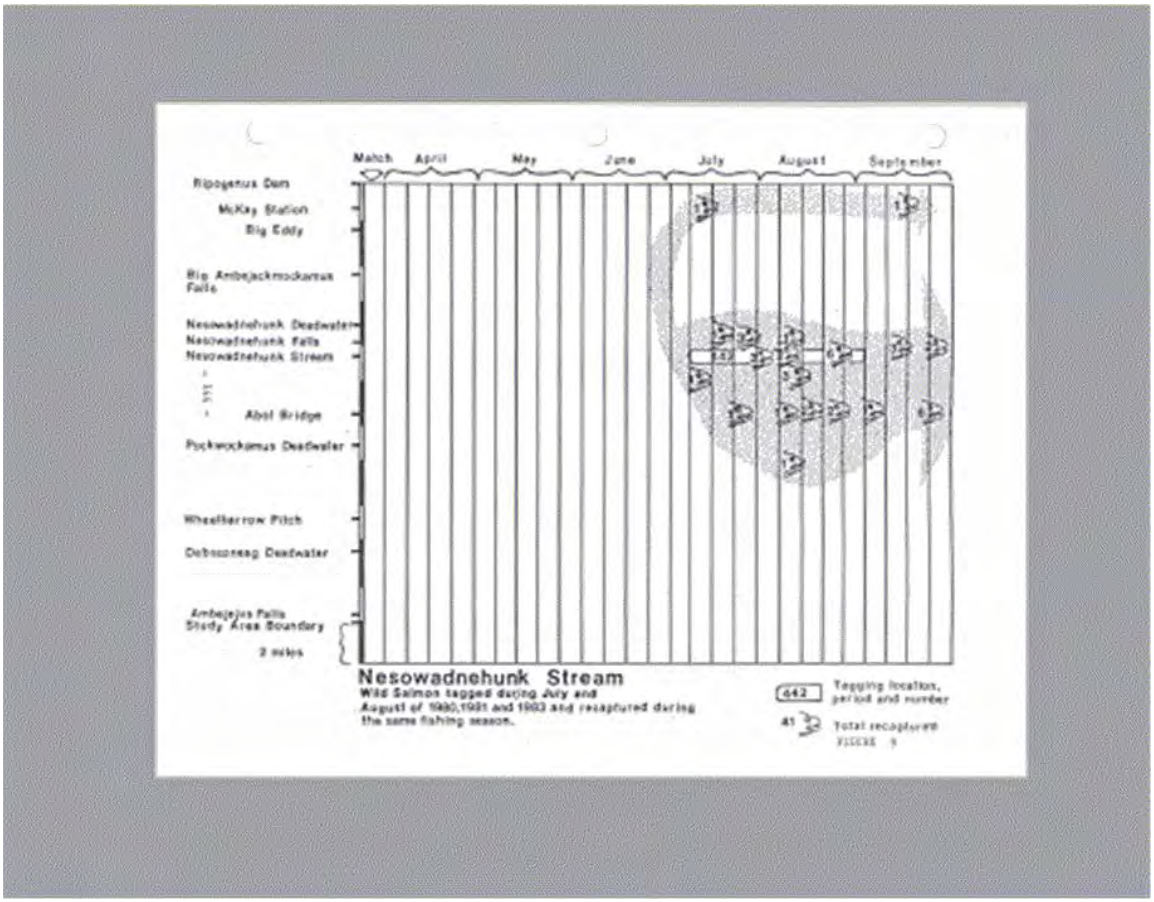
The Licensee adds that MeDIFW stated “no exo#c fish species are known to exist” (P 41). The meaning of this statement is unclear. Is exo#c used as a synonym for non-na#ve/non indigenous fish? The

Licensee has o%en been confused about indigenous and non indigenous fish species. For the record, yellow and white perch and smelt are not indigenous species. Salmon salar, the marine species was indigenous, the landlocked version were introduced circa 1890. The Licensee needs to clarify any differences between exo#c, non indigenous and well established or present species.

The Licensee also quotes MeDIFW's characteriza#on of non salmonid, exo#c species such as white and yellow perch as being abundant. "Abundant" is subjec#ve and useful as a fisheries management tool, but when quan#fying a fish community, "abundant" compared to what? What is the density in terms of fish or pounds per acre of white and yellow perch or smelt popula#ons? While shoreline boat electrofishing and trap ne' ng provided some useful informa#on, these are "shallow" water methods and thus biased and do not describe or quan#fy the impoundment's fish community. Moreover, yellow and white perch are species neither manage nor desired for by MeDIFW in Project waters.

The Licensee con#nues with the search of archival files, producing WB smelt data found in MeDIFW files, ci#ng it as MeDIFW work. This appears to be incorrect as 1999-2001 data (table 6) were collected by GNP. The misrepresenta#on con#nues. A casual reading would suggest that smelt were available in 2021 in the same abundance as in the 1980-1989 GNP sampling period. This is incorrect. A%er a ten plus year pause, GNP resumed smelt collec#on in 1999. All GNP smelt dri% net sampling ended in 2001. The GNP sampling protocol was that smelt dri% nets were set weekly for approximately 24 hours and "metered" (velocity/depth/width and #me fished). Annual es#mates of smelt biomass were made, in pounds rather than number. Typically, depending on month, there were between 450 (winter) to 1350 smelt (August) per pound. The MeDIFW samplings were based on #me available. Limited collec#on simply proves a few smelt were available during a certain period. The MeDIFW informa#on shown lacks lengths and weights from

individual fish. Whether the smelt were juvenile or older is unknown. Thus, any comparisons between the archival GNP smelt data and MeDIFW data are impossible. Any sugges#on as to the abundance of smelt (dri%), the key salmon forage item, in the West Branch remains largely unknown and is the most significant of the many data gaps, voids or black holes.



Results of Field Collec#ons

The Licensee undertook the fish assemblage study of the Ripogenus Impoundment in July and the electrofishing of West Branch of the Penobscot River below McKay Sta#on in August and September of 2022. No reason is given for the August electrofishing event when water temperatures were 22 C, and stressful for handling adult salmonids. While the results of these extensive efforts provide some useful insight of current fish popula#on, significant data gaps remain. Study results of the Ripogenus Impoundment demonstrate that the Lake Whitefish popula#on is either ex#nct or near ex#nc#on. While length data were not provided, the rela#vely large mean length of Ripogenus Impoundment smelt (Table 26) demonstrates the popula#ons are top-heavy with age II or older fish and out-of-balance and landlocked salmon growth is severely limited by the apparent lack of yearling smelt.

The August and September of 2022 electrofishing surveys of the WB failed to provide a comprehensive data set. For unknown reasons, scale samples were not taken from salmonids, thus no lengths at age are known. MeDIFW management objec#ves are commonly based on age classes and annual growth. Comparison between assemblage survey fish and salmon and trout collected during the 1978 – 1988 surveys which were filed as part of the 1991 license applica#on cannot be made.

The ini#al study plan appeared to call for electrofishing the river immediately below Nesowadnehunk Falls. For unknown reasons the

study area was expanded to include the area immediately below Nesowadenhunk Stream. This corrupted the results. The West Branch below Nesowadenhunk Stream along with the reach immediately above Abol Bridge are the major spawning staging loca#ons for North Twin Impoundment salmon (see below Vol IX Figure 9, 1991 Ripogenus License Applica#on). The photo shown in Appendix D- 81 shows two healthy salmon and one salmon in a degraded state. Is this a comparison of North Twin Impoundment salmon and West Branch salmon? It is likely that samples collected at Nesowadenhunk stream included and were perhaps dominated by North Twin Impoundment salmon.

Lake Whitefish

The Licensee failed to collect Lake Whitefish (Whitefish) despite extensive trap ne' ng efforts that included the area near Umbazookas Stream as it enters the Ripogenus impoundment. Numbers of Whitefish were collected at the same site during GNP's 1990 fall trap net survey. Although the Licensee's ISR states Whitefish had not been collected by MeDIFW since 1970, whitefish appeared in MeDIFW's 1996-2021 angler surveys (D-42) as well as GNP 1988-1990 winter angler surveys. Yoder 2005 lists Whitefish as being present (Table 4, Appendix D 40).

The Licensee appears to concede the Whitefish issue by providing an unsolicited excuse for the apparent Whitefish ex#nc#on. They claim Whitefish are declining statewide and the ex#nc#on of the Ripogenus popula#on is to be expected. The Licensee cites introduc#on of smelt and inter species compe##on as a cause. This is incorrect and, as is o%en the case, ignores facts.

Nearby Whitefish popula#ons are within walking distance of the Ripogenus Impoundment via the old Umbazookas and Eagle (and Chamberlin) Lake railroad right-of-way, presently a portage route. Addi#onally, and downstream of the Ripogenus Impoundment, MeDIFW reported Whitefish as recently as the 2022 winter creel survey of Pemadumcook lake (Table 51). These nearby Lakes are technically impoundments and share the commonality of having very limited, late summer drawdowns and smelt popula#ons that have existed for a hundred years. There is a clear nexus between the demise of whitefish in the Ripogenus Impoundment and the recent change in Project opera#ons to a market driven, earlier, and more dras#c drawdown regimes.

<u>Landlocked Salmon</u>

The Licensee's study of the West Branch below Mckay Sta#on provided virtually no informa#on on the abundance, distribu#on, growth,

movement and spawning success of sub adults and older salmon. Study design and equipment simply did not allow for sampling adult fish in deep water areas. The rela#vely few yearling and older fish, NOT COLLECTED from the Nesowadnehunk Stream pre-spawning staging area, demonstrated a popula#on with poor condi#on factors. The FWS requested, redd surveys were not undertaken. Thus, there is no informa#on on spawning and the subsequent impact of peaking flows on spawning and incuba#on success. Addi#onally, food habit informa#on was not collected and possible shi‰s in diet from one aqua#c invertebrate to another were not provided.

The Licensee apparently did not sample the West Branch below North Twin Dam in 2022. Considering the historic significance of this fishery, the omission is very strange. Instead, the Licensee repeats the "office study" and republished data collect by EBI in 2005 but fails to include 1991 data (GNP 1991). As deep water areas are precluded by sampling limita#ons, 2005 data collected by boat electrofishing are biased. This reach supported a significant landlocked salmon fishery in the 1980s and anecdotal informa#on was that this area supported a good salmon fishery in May, 2023. No effort is made to describe salmon popula#ons below Mill One or Dolby Dam despite historic abundance.

The Licensee has weaponize temperature and dissolved oxygen results and uses these data to dismiss "so called" marginal waters presently suppor#ng salmon produc#on. Salmon can find short term thermal refuge in the metalimnion or in riverine spring seepages. Fish, salmon in this case, are the proof of whether "marginal waters" can support salmon, not a computer spread sheet.

Rainbow Smelt

Despite a FWS request, there was no directed sample of smelt in either the Ripogenus or North Twin Impoundments or associated riverine

reaches. Juvenile smelt, less than a year old, are a cri#cal, perhaps the only significant prey item of adult salmon. Shi‰s in smelt abundance have been linked to the loss or shi%of li! oral zones, drawdowns and lake level fluca#on. Therefore, it is not surprising that the Licensee has avoided all efforts for any directed sampling of lacustrine or riverine smelt sampling.

From MeDIFW sampling of the Ripogenus Impoundment and an#dotal reports of the West Branch downstream of McKay Sta#on, it is clear that smelt, or at least juvenile smelt, no longer exist in abundances needed to support the historic high quality salmon fisheries. Although the North Twin Impoundment appears to be mee#ng MeDIFW management goals, informa#on on smelt in the impoundments and riverine reach of the Penobscot Mills Project is lacking. Fisheries in riverine areas below Mill One and Dolby remain a mystery.

The Licensee's fish assemble study was not designed to sample smelt, a spring spawner fish with pelagic tendencies. There was no directed sampling of Lacustrine smelt popula#ons. Despite the FWS request, there was no smelt sampling data provided. This is no longer a data gap. It has become a black hole designed to avoid shedding light on the current peaking opera#on and associated lake level management.

Lake Trout

The ISR lists Lake Trout as non-na#ve and MeDIFW no longer manages the Ripogenus Impoundment for this species. Addi#onally, Lake Trout spawn in the fall, o‰en in shallow areas and historic opera#on beginning in the 1950s with the start-up of McKay Sta#on would have limited recruitment. However, Lake Trout were apparently na#ve to upstream Caucomgomoc Lake and other nearby lakes. Early bathymetric maps of the Ripogenus Impoundment depicted a point known as Togue Ledge. It would seem reasonable to assume the name, Togue Ledge, was

connected to the deep water area around this point of land. Presumably, a historical Lake Trout fishery of unknown magnitude existed in that part of Chesuncook Lake (Ripogenus Impoundment).

Burbot (Cusk)

Historically Burbot (*Lota lota*) provided a directed winter fishery (often by set lines, at night) in the Ripogenus Impoundment (as well as the North Twin impoundment). The Licensee collected Burbot by trap net but not by electrofishing in the summer and early fall of 2022. As with longnose suckers, Burbot inhabit the bottom in deep water areas during May through September. Once impoundment waters cools, Burbot inhabited shallower areas and were a major by-catch in sampling shown in GNP 1991. The Licensee failed to provide weight distributions for the 36 Burbot it collected (Table 21), most of the Burbot appeared to be small, juvenile fish. Based on the Licensee's sampling the Burbot in the Ripogenus Impoundment, the population appears to in a major decline. The historic Ripogenus winter Burbot fishery is in jeopardy.

## 6.0 Summary

The Licensee provides several tables and figures that a! empt to show diversity in the fish popula#on of project waters. This is not informa#on that MeDIFW manages the fisheries resource with or that MDEP uses as they judge the "as natural occurring" standard of the Water Quality Cer#fica#on process. The abundance of white sucker, white and yellow perch is largely irrelevant. This summary material, while it iden#fies several species not found in the 1991 license Applica#on, fails to demonstrate that fisheries management goals or water quality standards are being met. In fact, the reverse is true. Taken at face value, Whitefish have been (apparently) expatriated. Salmon abundance and growth have declined. The Ripogenus smelt popula#on is "out of balance". The status of the Burbot popula#on is likely in decline as well.

The Licensee touts study results and takes a number of pages to discuss Biological Condi#on Gradient (BCG). The Licensee would suggest that a reading the of BCG would show the fisheries are in good health. This is incorrect. BCG finding although interes#ng have li! le relevance to relicensing issues. MeDIFW management goals are salmon and indirectly smelt. MeDEP standards include “as naturally occurs.” Improvised salmon popula#on in the Ripogenus Impoundment and the downstream West Branch are not mee#ng that standard. Non na#ve species such as white and yellow perch are a nega#ve on any species list where salmonid management is the goal.

The ISR ignores salmonid fisheries in the riverine reaches downstream of North Twin and Dolby Dam and the Millinocket facility. While some of these areas had limited access, at a minimum there were seasonal salmon fisheries during the 1985-1989 period. Boat electrofishing results, restricted by sampling gear, are no excuse for elimina#ng these reaches as areas capable of providing fishing opportuni#es. GNP 1991 creel survey data demonstrates that if suitable access is provided, significant fisheries would develop.

*Final comments*

The Licensee’s consultants expended a tremendous amount of effort sampling Ripogenus Project waters. Poor study design produced study results that created more ques#ons than were answered by study results. The tac#cal omission of GNP 1991 data and only par#ally including MeDIFW data further reduce the value of the April 24, 2023 ISR. The lack of the requested smelt data and salmonid scale samples for age-growth informa#on cannot be overcome by verbiage. Despite glowing statements concerning species richness, the reader is le% with the sense that the Ripogenus Impoundment and downstream West

Branch are in a precipitous decline when compared to GNP 1991, when FERC Licensed a non-peaking system.

At a minimum, FERC should request the Licensee revise Appendix D by addressing the above men#oned errors and omissions. Presently Appendix D is part of the record. Le% uncorrected the errors and omission provide li! le useful informa#on to the agencies, stakeholders and FERC Staff.

Thank you for the opportunity to comment.

**Re: MDIFW Comments on the Initial Study Report for the Ripogenus Hydroelectric Project (FERC No. 2572) and Penobscot Mills Hydroelectric Project (FERC No. 2458)**

Dear Secretary Bose:

On April 24, 2023, Great Lakes Hydro America, LLC (GLHA), a subsidiary of Brookfield Renewable (Brookfield, Licensee), submitted their Initial Study Report (ISR) for both the Ripogenus Hydroelectric Project (FERC No. 2572) and Penobscot Mills Hydroelectric Project (FERC No. 2458). The Projects are located on the West Branch of the Penobscot River and Millinocket Stream, and span both Piscataquis and Penobscot Counties, Maine. MDIFW attended the ISR Meeting on May 2-4, 2023, as well as the FERC Project Site Visit on May 5, 2023. We offer the following comments and New Study Requests below.

***Ripogenus Project Comments***

Recreation Study/Creel Surveys Discussion

There have been several questions raised by other stakeholders regarding angling information and the lack of this information in the Recreation report at the ISR meeting. While MDIFW typically requests this information as part of relicensing proceedings, we did not request clerk angler surveys from GLHA during the initial study requests. The following discussion is meant to clarify to FERC and other stakeholders MDIFW's rationale for not requesting clerk angler surveys as part of this relicensing proceeding.

MDIFW relies on several types of angler/creel surveys, depending on the situation. The primary goal of any survey is to collect catch per unit effort (CPUE) data for gamefish species that can be used to monitor trends over time. Therefore, the method of survey needs to be consistent. We cannot directly compare CPUE data gathered during a clerk survey with a voluntary box/book survey because voluntary data tends to be biased toward the more successful anglers. However, voluntary box/book data *can* be compared with other similar voluntary data over time, and to other waters where this type of survey has been conducted, although voluntary surveys do not typically include staff handling fish to evaluate age/growth or food habits.

By way of background, MDIFW remains the most underfunded fisheries agency in the United States:

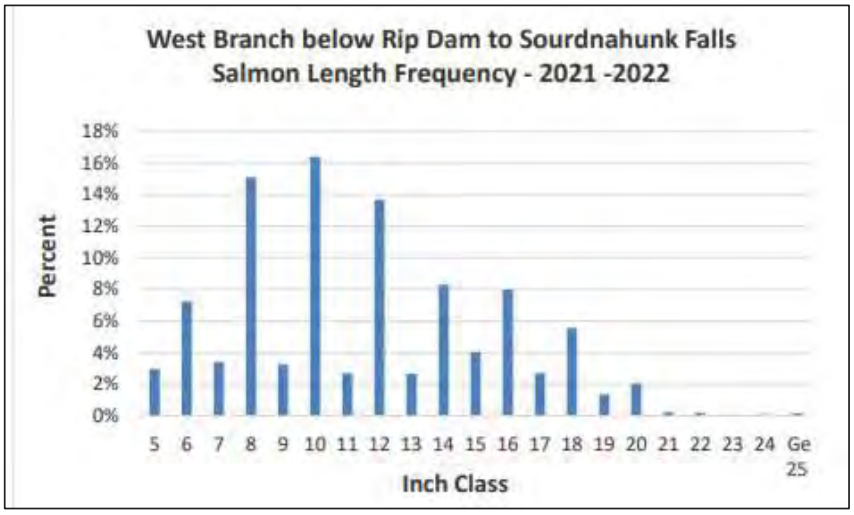
Maine currently gets the minimum distribution from the federal Dingell-Johnson fund, which is the main source of funding for our Fisheries Division, yet Maine ranks 13th among States regarding the amount of aquatic habitat to manage for sportfish. This discrepancy between aquatic habitat management and federal funding ranks Maine last. Moreover, the Moosehead Lake Region, where the Ripogenus Project is located, has nearly ¼ million acres of standing water and over 4,000 miles of flowing water--more water than six entire States. If all 50 States were listed by the amount of water present for sportfish management, the Moosehead Lake Region would rank higher than New Mexico, Connecticut, Delaware, New Hampshire, Rhode Island, and West Virginia, yet the Moosehead Lake Region only has three permanent fisheries staff. By comparison, New Mexico receives over $6.6 million from Dingell-Johnson funding annually. Moreover, the Moosehead Lake Region receives a very tiny portion from the $3.9 million total allotment to the State of Maine. Therefore, we must be judicious in planning our work, and as clerk surveys are labor-intensive, requiring staff to be on-site multiple days a week over the course of the entire fishing season, we do not have the available staff or equipment to conduct clerk angler surveys to replicate similar Licensee work on the West Branch of the Penobscot River into the future. We rarely conduct clerk surveys on any of the Region's rivers because we must utilize our available staff on Moosehead Lake (Maine's largest Lake), the Ripogenus Impoundment (Maine's 2nd largest lake), Chamberlain Lake (Maine's 10th largest lake), and other important waters. We frequently utilize voluntary box surveys on our river systems, and while we recognize that not all anglers participate, those that do tend to be the more successful anglers. However, if the data are collected in the same manner over time, trends in CPUE can be developed and compared on a yearly basis, and to other waters with similar data.

MDIFW plans to periodically collect CPUE data on the West Branch of the Penobscot in the future. Therefore, we must rely on a repeatable survey method. While it would be desirable to have the sufficient staff to conduct full clerk surveys on this large, important river (and many other locations in the Region), it just is not feasible due to current staffing levels.

Included below are results from the voluntary box census on the West Branch of the Penobscot 2021 – 2022 (Ripogenus Dam to Sourdnahunk Falls):

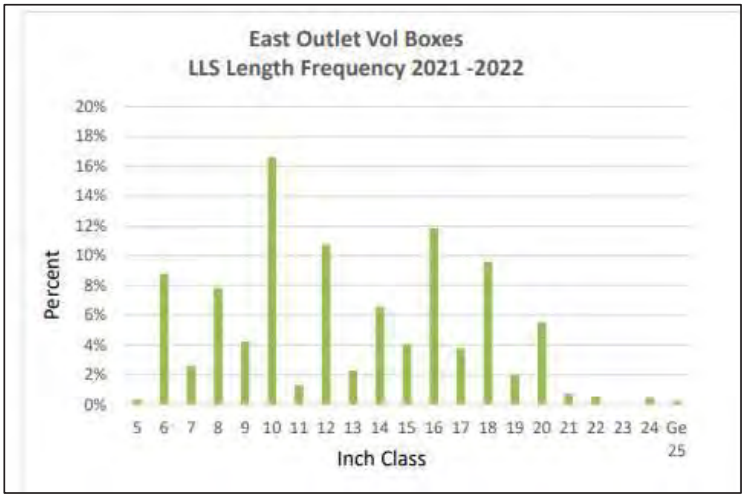
Voluntary box locations:

| Box number | Location |
|---|---|
| 1 | Sourdnahunk Falls |
| 2 | Sourdnahunk Deadwater/Horserace Campsite |
| 3 | Telos Bridge North Side Trail - Washing Machine |
| 4 | Holbrook Pool |
| 5 | Little Eddy |
| 6 | McKay Station Parking area |
| 7 | Rip Dam- Upper Gorge Trail |
| 8 | Big Eddy Campground |



Data Summary:

| | 2021 | 2022 |
|---|---|---|
| Parties | 356 | 216 |
| Anglers | 612 | 358 |
| Total Hours | 1545 | 762 |
| | | |
| Salmon Kept | 1 | 0 |
| Salmon Released | 863 | 748 |
| | | |
| Brook Trout Kept | 4 | 1 |
| Brook Trout Released | 178 | 75 |
| | | |
| All Salmon/hr | 0.76 | 0.99 |
| All Brook Trout/hr | 0.15 | 0.13 |



For comparison, these are the catch rates for landlocked salmon and brook trout in 2021 and 2022 from the nearby Moose River and East Outlet of the Kennebec River, which both have similar fisheries and similar clientele:

| | Moose River | East Outlet |
|---|---|---|
| All Salmon/hr | 0.37 | 0.49 |
| All Brook Trout/hr | 0.14 | 0.22 |

Below is the length frequency from angler caught fish reported in the voluntary boxes in the West Branch in 2021 and 2022. It is typical of a river system with all life stages of salmon present:

Length frequency data from the East Outlet of the Kennebec River is very similar to the West Branch of the Penobscot River:

MDIFW did not request angler surveys on the Ripogenus Impoundment because, as mentioned during previous meetings and in our filings, we have ample angler survey data, including summer and winter data as recent as 2021, to characterize the fishery. These surveys include CPUE, angler use, harvest, and age/growth data. As the Agency responsible for the management of the inland fisheries, MDIFW believes we have the information currently needed to assess the fishery and respond with management changes as necessary. We did not feel it would be useful to have outside sources (i.e., the Licensee) collect that information for one year, nor did we have the available staff or equipment to conduct a clerk survey in 2023. That said, we do plan to return to the Ripogenus Project and West Branch of the Penobscot River in 2025. We typically try to sample our larger waters, such as the Ripogenus Impoundment, every few years, with the exception being Moosehead Lake, which requires annual attention from our limited number of full-time staff. Therefore, sampling other waters relies on availability of additional funds for temporary staff. It is difficult to execute a basic, long-term fisheries management plan that would include angler surveys on the lake and river, trapnetting tributaries for salmon age/growth/abundance, and smelt drift estimates below McKay Station with the uncertainty in funding.

Smelt Entrainment

MDIFW knows from past studies that smelt drift (entrainment) from the Ripogenus Impoundment through McKay Station is essential to maintain growth of the downstream landlock salmon population. Studies conducted by Great Northern Paper (1985 - 1989, 1999 - 2001, and by MDIFW (2021) clearly demonstrate that hundreds of thousands of smelt from the Ripogenus Impoundment drift downstream and provide forage for the resident salmon population. Landlocked salmon rely on smelt for forage, to the exclusion of almost all other fish species. It has been well-documented that salmon growth, and sometimes survival, declines when smelt are less abundant. Smelt do not typically live in a river environment year-round and there are few, if any, resident smelt in the river itself. Therefore, it is critical to maintain smelt drift from the Ripogenus Impoundment. During our May 5, 2023, site visit to the Project with FERC staff, we stopped at the Holbrook Pool area and observed many gulls swooping down to pick up smelt that were drifting downstream from McKay. These fish are the primary food source for the West Branch salmon, especially in the colder seasons of the year when insects are less abundant. Any

efforts to reduce entrainment at Ripogenus Dam will likely have dire consequences on the important salmon sport fishery in the West Branch of the Penobscot River below the dam.

Fish Assemblage Study Discussion

From MDIFW's perspective, the results from the Fish Assemblage Study were as expected. The fish species identified by GLHA in the Ripogenus Impoundment and the West Branch below the Ripogenus Impoundment are consistent with MDIFW's species inventory for these waters and are typical of waters in that region. We understand this study was intended to simply identify species and not provide any meaningful indices of abundance, which would be impossible given the size of the lake, and the various species and life histories involved.

Flow data - Ramping/Peaking

MDIFW is concerned with potential changes in Project operations since the Millinocket paper mills closed that might increase the frequency and rate of flow changes in the West Branch below McKay Station. GLHA has recently provided hourly flow data for review, and MDIFW analyses of those data indicate that the majority of flow changes (increase or decrease) do not appear to exceed 25% of the initial flow. This criterion (25% of existing flow) is based on existing ramping studies. Smokorowski[1] compared biotic factors from a regulated river to a nearby unregulated river. In the regulated river, the summer ramping rates were limited to 25% of the previous hours flow. The report concluded that: *"Constrained ramping operations result in changes to the flow regime that on the whole are ecologically protective as indicated by some of the measured biological metrics reported here for the Magpie River. Invertebrate abundance and diversity, fish biomass, fish condition, and food web length were all equal to or greater than our unaltered system, and some metrics that differed between rivers, specifically isotope signatures, were attributed to the presence of the reservoir and not to flow alterations."*

Based on MDIFW's analyses, of the 192,000+ flow observations from McKay Station analyzed to compare flow at hour(n) to hour(n+1), less than 2% exceeded a change in discharge greater than 25%. The data were broken down by period as follows:

Period 1: 2000 – 2007 (mills operational)
Period 2: 2008 – 2013 (transitioning period – mills closing)
Period 3: 2014 – 2022 (post-mill operation)

The results were as follows:

NUMBER OF HOURLY FLOW OBSERVATIONS AND PERCENT EXCEEDING 25% OF EXISTING FLOW 2000-2022

| PERIOD | TOTAL OBS | NUMBER OF FLOW CHANGES EXCEEDED 25% | PERCENT |
|---|---|---|---|
| 1 | 66,964 | 1,079 | 1.6 |
| 2 | 50,353 | 522 | 1.0 |
| 3 | 75,361 | 800 | 1.1 |
| ALL | 192,678 | 2,401 | 1.2 |

[1] Smokorowski, K. & Metcalfe, Robert & Finucan, S. & NE, Jones & Marty, Jerome & Pyrce, R. & Steele, R. (2011). Ecosystem level assessment of environmentally based flow restrictions for maintaining ecosystem integrity: A comparison of a modified peaking versus unaltered river. Ecohydrology. 4. 791 - 806. 10.1002/eco.167.

The flow data were also examined to determine the number of days where a flow change exceeded the 25% threshold. The results were as follows:

NUMBER OF DAYS WITH HOURLY FLOW CHANGES THAT EXCEEDED 25% OF EXISTING FLOW
2000-2022

| PERIOD | TOTAL NUMBER OF DAYS WITH AN HOURLY FLOW CHANGE EXCEEDING 25% | PERCENT |
|---|---|---|
| 1 | 620 | 21.2 |
| 2 | 334 | 15.3 |
| 3 | 490 | 14.9 |
| ALL | 1,444 | 17.2 |

This analysis of all the observations would indicate that any perceived changes in flow management since the mill closures have not resulted in more frequent occurrences of hourly flow changes greater than 25%. Still, the current 14.9% of days with flow changes greater than 25% represents an opportunity for improvement in the future license.

Stranding Study/Low Flow Events

Based on MDIFW's analyses of data between 2000 and 2022, there were 40 days with a low flow event of 500 cfs or less (**Table 1 below**). This seems high compared to other hydro and storage facilities in the Region. There were many other days where the flow was between 500 – 1000 cfs, but it is clear these low flow days were the result of drought conditions and flows were likely reduced with consultation (i.e., many consecutive days during dry years where the flow was stable but less than the minimum flow of 1,000 cfs.)

In light of this new information made available after the ISR meeting, MDIFW requested GLHA to provide a brief description/clarification of the cause of the low flow events on these 40 days. As documented in the Stranding Study, flow excursions to 500 cfs and lower can cause significant disturbance and mortality. These events appear to have occurred in 17 of 23 years in the sample which likely led to significant losses of young landlocked salmon (multiple age classes), brook trout, and other species. Many of these low flow events may be unavoidable, but future low flow events should be minimized and, in some cases, be mitigated for in the upcoming license.

**Table 1. Low Flow Events - 2000 to 2022**

Lake Elevation Data - Ripogenus Impoundment Elevations Analysis

In their PAD, GLHA states that the lake elevations remain "*relatively stable*". The old Water Management Plan (WMP) curve below shows an approximate long term average drawdown from May to September of approximately 4 feet.

Based on the revised data in the old WMP, full pond is closer to 936.5 feet, and the lake elevation should stay above approximately 934 feet during the growing/recreation season of May to September. That elevation is depicted on the following chart along with the actual lake elevations.

Long-term averages in the WMP from the previous license.

Examining the recent data provided by GLHA (see tables below), the summer drawdown on the impoundment ranged from approximately 4 – 19 feet from 2000 to 2022. There was only 1 year in which the total drawdown was near 4 feet. The tables below show that the mean drawdown during May-September is higher in Period 3 (post mill operation). This Period also includes 2020 and 2021, two severe drought years. When the drought years are removed from the analysis, the mean difference in summer drawdowns from Period 1 and Period 3 is 0.6 feet.

Mean drawdown on Rip Impoundment by Period for May-Sept
All Years

| | ELEVATION | |
|---|---|---|
| | min | max |
| YEAR | | |

***Penobscot Mills Project Comments***

North Twin Impoundment Tributary Access Survey Study

In the Initial Study Request MDIFW proposed a Comprehensive Impoundment Landlocked Salmon Habitat Use/Spawning Study be conducted. This proposal, in part, called for capturing, radio tagging, and monitoring landlocked salmon in the North Twin headpond, an 18,300-acre waterbody comprised of five continuous waters: Ambajejus, Pemadumcook, North Twin, South Twin, and Elbow Lakes. However, the Licensee modified the original proposal and removed the radio tagging portion of the study which would have indicated habitat use of landlocked salmon within the Project area. Instead, the Licensee proposed,

and FERC accepted, a North Twin Impoundment Tributary Access Survey Study to document whether Project operations on headpond water levels affect salmon access to tributaries during fall spawning activities.

During 2022 discussions, MDIFW and the Licensee identified eight tributaries at the North Twin Impoundment which might contain landlocked salmon spawning habitat. After the Summer 2022 field assessment of identified tributaries, it was determined by the Licensee and MDIFW that the fall spawning surveys would concentrate on three tributaries with adequate salmon spawning habitat: West Branch Penobscot River, Nahmakanta Stream, and Jo-Mary Stream. The remaining five tributaries were determined not to be suitable for salmonid spawning and therefore no follow-up fall spawning surveys were warranted. However, as discussed during the ISR Meeting, and as stated in Appendix G: North Twin Impoundment Tributary Access Survey Study contained in the ISR: "*Field conditions were unsuitable in fall 2022 for completing the tributary surveys. Extended rainfall in October and November 2022 resulted in abnormally high impoundment water elevations and high tributary runoff that precluded surveying. Brookfield anticipates conducting this survey in 2023."*

Radio tagging a small number of landlocked salmon at the North Twin Impoundment, as suggested in the original study request proposed by MDIFW, would have possibly yielded some insightful data in the fall of 2022 during "abnormally high" water levels. It is generally accepted that salmon utilize large inlets and outlets for spawning and rearing.[2] However, it has also been documented that landlocked salmon will spawn in lakes, especially near mouths of large inlets, in moving water near outlets, and among wind-swept shoals (Boucher and Warner). The Licensee's methodology to conduct a tributary access study, without radio tagging salmon, will not identify whether spawning activity is occurring within the lacustrine habitat of the North Twin Impoundment, especially if salmon are utilizing unknown shoals, and if Project operations are impacting these areas.

Realizing the inability to proceed with the present study in 2022, and that potential unpredictable environmental conditions could take place again in the fall of 2023, MDIFW is re-requesting that the Licensee radio tag landlocked salmon (sample size and sex ratios to be determined through consultation) as part of a Landlocked Salmon Habitat Use/Spawning Study (below), as originally submitted. Relying on visual redd counts alone will not yield reliable information related to what effects, if any, fall impoundment-level fluctuations may have on salmonid spawning success. Surveying tributaries by sight alone will not provide data related to potential lacustrine-based spawning activities.

**Riparian and Littoral Habitat Assessment Study Discussion—Ripogenus and Penobscot Mills Projects**

MDFW appreciates the efforts showing that the Riparian and Littoral Habitat Assessment documented ongoing impacts to wetlands in the impoundments of the Projects, as expected. Under the existing license, after a series of studies and resulting reports, wetland impacts were mitigated mainly via the discontinued storage-and-release operation at Umbazooksus Lake in Spring 1998 by maintaining the outlet gate in a permanently opened position, resulting in a run-of-river regime to lower water levels and enhance wetlands at Umbazooksus Lake. Subsequent monitoring indicated that wetland vegetation and species richness increased, and it was estimated that 320 acres of wetlands were recovered.

[2] Boucher, David and Warner, Kendall, "Maine Landlocked Salmon : Life History, Ecology, and Management" (2006). Inland Fisheries and Wildlife Documents. 65. https://digitalmaine.com/ifw_docs/65

However, as requested in our October 8, 2021, Study Requests and as reiterated in our April 7, 2022, Revised Study Plan Comments, MDIFW expressed the need to document impacts resulting from Project operations to the West Branch of the Penobscot River downstream of Ripogenus Project to the Penobscot Mills Project, as well as the West Branch below Stone Dam and Millinocket Stream, and to associated riverine wetland habitats. It is our understanding that this aspect was not considered as part of the overall Riparian and Littoral Habitat Assessment, and MDIFW again reiterates our concern to account for impacts to these resources and the species that occupy or potentially occupy these resources. To restate, many of documented, modeled, and predicted State Species of Greatest Conservation Need (SGCN, see below), including State Threatened aquatic or aquatic-associated invertebrate species in the Project area, require specialized experience, specific survey protocols, and proper seasonality to detect, and most of these species below, if present, will not be documented through general wildlife surveys. As part of this relicensing effort, MDIFW is considering comprehensive minimization efforts and mitigation scenarios for the new licenses accounting for lacustrine, palustrine, and riverine habitat impacts and for the species, including SGCN species, that utilize these habitats, based on our current management objectives and current mitigation requirements. One aspect of possible mitigation that MDIFW is considering is the Umbazooksus Lake mitigation area, and we are exploring whether this site alone is adequate to account for anticipated impacts from future operations for all species and varying habitats affected by operations of both Projects. To that end, MDIFW is requesting a new study (below) to evaluate the Umbazooksus Lake mitigation component of the current license to see if this area can be further enhanced as a mitigation component for the new Ripogenus Project license.

***New Study Requests***

We respectfully request that FERC adopt the following New Study Requests below. To be clear, our Agency is utilizing this limited period of time between 30- to 50-year Federal licenses to become better informed on how current Project operations are affecting inland fisheries and wildlife resources and their respective habitats in the Project areas, as well as better understand public access and use at the Projects.

**New Study (Information) Request 1: USGS gage feasibility study—Ripogenus Project**

1. We recommend GLHA work with the appropriate USGS representatives to provide an estimate of cost for a new USGS gage on the West Branch of the Penobscot River at a location below McKay Station and above Big Eddy Campground. The goal of this "study" is to eliminate the significant stakeholder confusion around the issue of monitoring discharge in the river and the methodology for estimating the flow at the Ripogenus Project, as discussed during the ISR meeting in May 2023.

2. This is an important, heavily regulated river system with multiple agency and user group interests, oftentimes with competing goals. A standard USGS gage in the system where river flow and Ripogenus Impoundment elevations at 15-minute intervals could be accessible on the USGS website would be invaluable for these groups, allow for a level of predictability for all users, as well as for determining compliance, particularly during climatic extremes. The first step in implementing a gage is to understand the costs and logistics of installing one in this remote region.

3. MDIFW is a cabinet level agency of the State of Maine. Under Maine State Law (12 MRSA, §10051), MDIFW's mandate is *"…to preserve, protect, and enhance the inland fisheries and wildlife resources of the State; to encourage the wise use of these resources; to ensure coordinated planning for the future use and preservation of these resources; and to provide for effective management of these resources."*

4. Prior to the ISR meeting, it was unknown to stakeholders how discharge was calculated from the Ripogenus Project. It was apparent to all stakeholders who attended the ISR meeting that the determination of discharge from the Project is still not easily ascertainable to the layperson. Understanding the costs associated with a USGS gage is the critical first step in exploring the installation of a new gage for the next license.

5. Understanding real-time discharges allows the resource and regulatory community to make more informed management decisions, especially during extreme climatic conditions which appear to be occurring in greater frequencies. A USGS gage would also allow multiple interested users to better understand the amounts and durations of any license compliance deviations.

6. We are unsure if this request has been made at other hydro facilities in Maine. We do not consider this as a true "study request" in the scientific sense.

7. The level of effort and cost is commensurate with a project the size of the Ripogenus Project and the probable license term. We anticipate a relatively straightforward process of the Licensee connecting with the appropriate staff at the USGS, determine the proper and practical location for a new gage, and the estimated costs of installing a gage in this region. We anticipate no more than 5 days of communications, including time to prepare a report memo which documents staff correspondence, proposed locations for a gage, associated costs for installing a gage, and any alternatives for installing a gage.

**New Study Request 2: Recreation Study/Winter Access Study—Ripogenus Project**

1. MDIFW requests an updated evaluation of wintertime angling access at the Ripogenus Impoundment. MDIFW believes winter angling and snowmobile access is limited at the Chesuncook Point access site, which is the primary access site to the Ripogenus Impoundment in the winter. It is important to maintain and promote winter angling and access on the impoundment. It is currently MDIFW's goal to increase harvest of salmon in the impoundment, and most of the annual salmon harvest occurs in the winter months.

2. In addition to responsibilities regarding inland fisheries management, MDIFW is charged with improving and securing public access to waters of the State of Maine. This wintertime study is requested because MDIFW is concerned that use was under-represented this past winter as the ice formed very late making it unsafe for travel through all of January; as a result, winter use was reduced in 2023 and therefore atypical during GLHA's Recreation Study period.

3. MDIFW is a cabinet level agency of the State of Maine. Under Maine State Law (12 MRSA, §10051), MDIFW's mandate is *"…to preserve, protect, and enhance the inland fisheries and wildlife resources of the State; to encourage the wise use of these resources; to ensure coordinated planning for the future use and preservation of these resources; and to provide for effective management of these resources."*

4. From our Agency's perspective, it is important to document current, accurate, and quantitative use during the winter as most of the annual salmon harvest at the Project occurs during the winter. As stated above, winter use of the Project area during the original Study period was not typical due to late formation of ice.

5. Operation of the Ripogenus Project has a direct impact on public recreation both above and below the dam. Given our Agencies management goal of increasing the harvest of salmon at the impoundment, understanding snowmobile access and use at the Chesuncook Point access site is critical to our management objective and the promotion of this resource.

6. Public recreation studies are a mainstay in FERC hydroelectric relicensing, and these data are basic, yet crucial to understanding how winter recreationalists access the area, utilize the area, if access is adequate, and what impacts the Project may have on those activities. The survey should include site visits on each Saturday between 10:00 am – 1:00 pm from January 15th through March 31st. The Study should include evaluating the capacity at the parking area and ease of access/conditions from the Golden Road. The access road is narrow, and at times difficult for two vehicles with trailers to pass each other.

7. The associated cost of this evaluation is commensurate with a project the size of the Aziscohos Hydroelectric Project and the likely license term. MDIFW is asking for additional information collection during this effort to ensure adequate wintertime public access over the life of the new license. It should be noted that MDIFW is not requesting a user contact survey which is both labor intensive and costly. Instead, we request the Licensee collect information on all recreation access points and determine overall use by area and user type.

**New Study Request 3: Umbazooksus Lake Mitigation Evaluation**

1. As provided in the initial Riparian and Littoral Habitat Assessment Study report, Project operations continue to impact the quantity, quality, and function of Project wetlands. The goal of this Study

Request is to evaluate Umbazooksus Lake as a possible wetland mitigation component for the new license, including evaluating potential enhancements. As such, we are requesting the following:

1.) Provide a map of the current locations of the wetlands that exist at Umbazooksus Lake.
2.) Provide a summary of the wetland acres by wetland type.
3.) Provide an analysis of the feasibility of adding increased water on this impoundment, by using splash boards or similar alterations to the current dam, to add one to four feet of additional water on this impoundment, in one-foot increments.
4.) Provide an analysis of the potential change in wetland acres by type, and location, when adding each incremental foot of additional water.

It should be noted that it was our Agency's understanding that that the proposed Umbazooksus Lake mitigation area, as well as the Penobscot Mills Wildlife Management Area, would be considered conserved in perpetuity; this misunderstanding was corrected during the ISR meeting when we were informed that for FERC relicensing purposes, mitigation is considered license term to license term. This new understanding is some of the reasoning behind this Study Request.

2. MDIFW is the natural resource agency responsible for managing inland fish and wildlife resources in the State of Maine, with "wildlife" defined as all animals, including insects and other macroinvertebrates, as well as the habitats necessary to complete their life history requirements. It is anticipated that ongoing Project operations will continue to impact natural resources; therefore, appropriate mitigation will be necessary after all practicable avoidance and minimization efforts have been realized.

3. MDIFW is a cabinet level agency of the State of Maine. Under Maine State Law (12 MRSA, §10051), MDIFW's mandate is *"…to preserve, protect, and enhance the inland fisheries and wildlife resources of the State; to encourage the wise use of these resources; to ensure coordinated planning for the future use and preservation of these resources; and to provide for effective management of these resources."*

4. As part of the last license for the Ripogenus Project, FERC required the Licensee to provide wetland mitigation for Project operational impacts on wetlands. This included removing Umbazooksus Lake as a storage impoundment for the Project by permanently opening the gate in the dam to allow for run-of-the river flows to potentially enhance wetland acres. According to the reports of follow up assessments on wetlands in Umbazooksus Lake from 1998-2004, this procedure increased wetland acres and plant species diversity within wetlands. MDIFW is interested in evaluating whether the Umbazooksus Lake mitigation area, including the incremental water levels increases as proposed to be studied, will be commensurate not only in acreage, but also in composition and functionality to species being impacted by Project operations, with the anticipated impacts that will occur during the 30–50-year term of the new license.

5. It is anticipated that wetland impacts, including anticipated impacts to the species which utilize these habitats, will likely occur during the term of the new license. Therefore, an evaluation of mitigation proposals, including an evaluation of Umbazooksus Lake enhancements, to offset possible impacts to Threatened, Special Concern, and SGCN species, as well as aquatic furbearers, is necessary.

6. After avoidance and minimization efforts have been realized, a discussion and assessment of perspective mitigation scenarios is common during the relicensing process. The Umbazooksus Lake area served as mitigation for wetland impacts for the current license, but as our understanding regarding the occurrence, distribution, and abundance of species and their habitat requirements has broadened since the issuance of the current license, our Agency's management objectives and focus has changed. As our

understanding has grown, exploring mitigation for the current license may not be sufficient for the future license

7. MDIFW asserts that the level of cost and effort is commensurate given the current and proposed operations of the Project. While near accuracy is of the utmost importance, MDIFW envisions that a desktop, GIS-based exercise will be sufficient for completing the evaluation. As additional water at 1-foot increments (up to 4 feet, with the existing regime as the baseline) at Umbazooksus Lake are evaluated, inclusion of any aerial imagery existing photographs would also prove instructive. The results should include descriptions of acreages and compositions of modeled wetland types released at each level evaluated, as well as a narrative of expected wildlife resources expected to utilize each wetland type. We estimate that this effort would likely require several days of GIS analyses, review, and reporting to summarize findings.

**New Study Request 4: Penobscot Mills Bypass Channel Fishability/Wadability Study**

1. The goal of this study is to inform the decision process for determining the suitable range of flows that allows for the safe wadability and fishability in the West Branch of the Penobscot River downstream of Stone Dam (Bypass Reach). MDIFW is looking to maximize fishery resources in terms of both aquatic habitat and fishable opportunities in this reach of river.

2. Concurrent with the perspective minimum flow findings of the Instream Flow and Habitat Assessment of West Branch Downstream of Stone Dam Study (Habitat Assessment Study), this study is requested to ensure that any agreed upon flow releases in the ranges of the identified suitable flows for salmonids occur at levels that are wadable and fishable while maintaining adequate habitat. The Habitat Assessment Study identified Aquatic Base Flow for this portion of the West Branch at 700-800 cfs. Given the nature of this reach of river and given that the current minimum flows are far below this range under the current license so that a fishery was not able to be established, assessment of fishability has not been undertaken to date.

3. MDIFW is a cabinet level agency of the State of Maine. Under Maine State Law (12 MRSA, §10051), MDIFW's mandate is *"…to preserve, protect, and enhance the inland fisheries and wildlife resources of the State; to encourage the wise use of these resources; to ensure coordinated planning for the future use and preservation of these resources; and to provide for effective management of these resources."*

4. Under the existing FERC license, minimum flows are not required in the Bypass Reach. The Bypass Reach is a 4.5-mile-long reach downstream of Stone Dam (Millinocket Impoundment) that flows into Shad Pond. The results of the Habitat Assessment Study indicates that a flow of approximately 700 cfs appears optimal for landlocked salmon; however, flows that are optimal for fish may not be suitable for wading fishermen. Anticipating a future minimal flow release requirement for Stone Dam, MDIFW will explore a limited salmonid stocking program in this stretch of the West Branch Penobscot River. Given the rugged nature of this reach of river, lack of previous flow-rate data and site-specific information, a fishability/wadability study is necessary to evaluate safe angler access to, and within, this stream reach before a stocking program could be implemented.

5. Fishability studies are often required during relicensing proceedings as daily, or seasonal, project operations can directly influence angling opportunities. An evaluation of fishability is necessary to determine how to best assess suitable and safe fishability/wadability flows, while maintaining adequate salmonid habitat through various project water releases at Stone Dam. Through this study, if a suitable

wading flow can be identified, there will likely be a need for improved vehicle access to the river stretch below Stone Dam as well as prominent safety signage alerting anglers of possible river level and flow fluctuations based on project operational needs.

6. This study request may parallel other stakeholder study requests and should be a collaborative effort between MDIFW, other interested parties, and the Licensee. Therefore, the study details, including the actual methodology, should be developed after a review of any similar study requests to minimize redundancy and meet the collective need for flow suitability analyses. However, for the purpose of more clearly addressing expectations, MDIFW envisions a Fishability Study consisting of experienced and lay-anglers assessing an agreed-upon range of flows at various locations within the Bypass Reach. Whereas a fishery has not been established in this reach, MDIFW also envisions potential assessment sites to be identified by ISR researchers and Brookfield staff familiar with this river reach. MDIFW and interested resource agency staff and anglers, along with the Licensee, could visually rate various flow(s) with the intent of identifying a range of suitable fishing flows. The actual test flows would be selected through a collaborative process involving MDIFW, other interested parties, and the Licensee.

7. The level of effort and cost is commensurate with a project the size of the Penobscot Mills Project and the likely license term. Several days of field work and subsequent analyses may be needed to assess pre-determined locations of the river under various flow scenarios. Only an evaluation of flow scenarios conducted in situ can effectively determine the best range of flows for fishability/wadability of this reach of river. The Licensee should coordinate with MDIFW, area guides, local anglers, Trout Unlimited, and other interested parties to ensure a representative collection of anglers are present during the multi-day assessment.

**New (Re-requested) Study Request 5: Landlocked Salmon Habitat Use/Spawning Study—Penobscot Mills Project**

1. This study will document the seasonal movement of landlocked salmon in the North Twin Impoundment area (includes Ambajejus, Pemadumcook, North Twin, South Twin, and Elbow Lakes) as well as identify salmon spawning areas.

Objectives:

- Identify landlocked salmon spawning areas within the North Twin Impoundment, and determine effects of Project drawdowns on spawning
- Determine the effects of annual Project drawdowns on the movement and behaviors of landlocked salmon in the impoundment
- Track seasonal movements and behaviors of landlocked salmon (within and between the five connected lakes) via radiotelemetry
- Assess tributary access and conduct tributary redd counts utilizing information obtained from tagged salmon movements
- Collection of biometric data to characterize landlocked salmon population dynamics

This study is being re-requested by MDIFW because the 2022 North Twin Impoundment Tributary Access Survey Study, as designed, is unable to document whether landlocked salmon spawning is occurring in the drawdown zone of North Twin Lake. Moreover, currently data is lacking documenting the exact locations of spawning for landlocked salmon at the North Twin Impoundment area. It is conventional thought salmon use larger tributaries of North Twin for spawning, particularly Nahmakanta

Stream (Pemadumcook Lake) and the West Branch Penobscot River (Ambajejus Lake inlet). However, the North Twin Impoundment is nearly 18,000 acres with numerous smaller tributaries in the impoundment which contain documented spawning habitat, yet it is unknown if salmon have the ability to access these tributaries for spawning.

2. MDIFW is the State Agency responsible for managing the inland fishery resources in Maine. The lakes within the North Twin Impoundment are managed primarily for brook trout, landlocked salmon, lake trout, and rainbow smelt. Populations of these species are maintained through a combination of annual stocking (brook trout), semi-annual stocking (lake trout), and natural reproduction (landlocked salmon).

3. MDIFW is a cabinet level agency of the State of Maine. Under Maine State Law (12 MRSA, §10051), MDIFW's mandate is *"…to preserve, protect, and enhance the inland fisheries and wildlife resources of the State; to encourage the wise use of these resources; to ensure coordinated planning for the future use and preservation of these resources; and to provide for effective management of these resources."*

4. The North Twin Development operates as a store-and-release facility. From August 22 to October 15, the impoundment is maintained above elevation 488.42 feet (within 3.5 feet from normal full pond elevation). From October 15 to the start of the freshet, the impoundment elevation is gradually reduced to a lower target elevation of 479.42 (12 feet from normal full pond elevation) to provide storage for winter thaw and spring flows. MDIFW is not aware of any previous studies or data summaries focused on landlocked salmon movement and spawning habitat/tributary use as related to the North Twin Impoundment in particular, nor the Penobscot Mills Project in general. This information would be invaluable to the Department's efforts of managing a (in recent years) naturally reproducing population of landlocked salmon to maintain a quality fishery in the nearly 18,000-acre North Twin Impoundment.

5. Landlocked salmon were historically stocked periodically in the North Twin Impoundment by MDIFW for 17 of the 36 years between 1937 and 1973, then annually from 1976 to 2010, and 2014-2017. A continuously decreasing number of salmon were stocked during the 2014-2017 timeframe. Stocking of landlocked salmon ended in 2017 after MDIFW gill net surveys at the time indicated a large percentage of captured salmon were of naturally reared origin. Presently, landlocked salmon in the North Twin Impoundment consist of a self-sustaining naturally reproducing population relying on adequate and accessible spawning habitats. The Department is continuously striving to improve the salmon fishery to a healthy balance, and with that maintain an equally healthy population of rainbow smelt, the primary prey species of landlocked salmon. As outlined in the PAD, under the current operating license issued in 1996, Article 408 required the Licensee to maintain the North Twin Impoundment at a minimum target level of 488.42 feet for the period August 22 through October 15 to accommodate lake trout spawning and incubation in October. However, after periodic lake trout monitoring during the early 2000's, it was determined wild lake trout reproduction was not occurring in the impoundment. Therefore, Article 408 was amended in 2012 to remove the minimum target lake elevation level during the period August 22 through October 15. With the minimum target lake elevation now removed, MDIFW believes that the Project's seasonal drawdown cycles could have a negative impact on landlocked salmon spawning and incubation within the impoundment and its tributaries. This study will also assist MDIFW on how best to manage the fishery and determine if significant lake level drawdowns are impacting salmon life movement, foraging, or spawning within the shoreline or movement up tributaries within the Project.

6. Radiotelemetry studies are routinely requested and utilized during the hydro relicensing process in Maine and elsewhere. Similar radiotelemetry studies have been proven essential to developing management plans for the Rapid River and West Branch fisheries, and similar studies at Moosehead Lake

above the East Outlet Dam (FERC No. P-2671), Brassua Lake above the Brassua Dam (FERC No. P-2615), and in the Kennebec River downstream of Indian Pond Project (FERC No. P-2142) have been completed in recent years. The proposed study may be similar to other projects occurring at other hydroelectric projects but should include a sample size large enough to fully assess all movements including regular tracking events. Radiotelemetry is a highly effective means of determining salmonid movement and habits and determining potential Project-related impacts to their populations.

7. This study is commensurate with the scale of the Project, presumed new 40-year operating license, and the importance of the resource. The level of effort and cost, to include multi-season sampling, is consistent with an impoundment of this magnitude. MDIFW needs a better understanding of the movement and spawning of naturally reared landlocked salmon fisheries in the North Twin Impoundment and how the Project may or may not be impacting these fisheries to achieve MDIFW management goals.

The natural resources and other concerns associated with these Projects are very complex, and we appreciate the Licensee's ongoing commitment to work through these issues. Please feel free to contact my office if you have any questions regarding this information, or if I can be of any further assistance.

Best regards,

John Perry

Penobscot Mills Hydroelectric Project (FERC No. 2458 RE: Comments on the initial Study Report and Support of Maine Department of Inland Fisheries and Wildlife's Request to Radio Tag North Twin Impoundment Landlocked Salmon

In the June 30, 2023 filing The Maine Department of Inland Fisheries and Wildlife (MeDIFW) commented on Initial Study Report (ISR) North Twin Impoundment Tributary Access Survey Study results. MeDIFW stated "Licensee modified the original proposal and removed the radio tagging portion of the study which would have indicated habitat use of landlocked salmon within the Project area". The results provided by the ISR failed to provide new information.

That Landlocked salmon (salmon) spawn in Nahmakanta Stream has been known for over fifty years. Possible barriers to spawning areas were surveyed in the late 1980s and included in Great Northern Paper's 1991 Application. While salmon redds were observed by the 2022 study team, the origin of these fish is unproven as is the delays or difficulties these fish may have encountered as they left the impoundment. The ISR mistakenly assumes the salmon and redds observed in Nahmakanta Stream originated in North Twin Impoundment. Redds observed in Nahmakanta Stream could easily been from upstream stocks e.g. Nahmakanta or Joe Mary Lake or strays from the West Branch of the Penobscot River.

Any valid tributary access study must include salmon caught and radio tagged in one of the North Twin Impoundment's basins. Salmon captured in September would be followed until the completion of spawning by mid-November. In as much as North Twin salmon

historically spawned in the West Branch, at a minimum a data logger should be located at the Grant Brook Bridge. Known spawning areas below Abol Bridge and Pockwockamus Falls should be included on a time available basis.

In order to account for straying, I suggest that 20 adult fish each from South Twin, Ambajejus, and Pemadumcook basin radio tagged. Trap net fish can be held in holding pens until tagging. Fish should be released at predetermined sites in each of the three basin. Under high attraction flows, salmon have been known to move to spawning areas as early as August. Thus, rain events need to be taken into account.

If the tributary study is to have any validity, radio tagging must be part of the study. Present study results found in the ISR provide no useful information. I ask FERC to order radio tagging of North Twin Impoundment salmon.

Thank you for the opportunity to comment

AMERICAN WHITEWATER AND APPALACHIAN MOUNTAIN CLUB COMMENTS ON INITIAL STUDY REPORT AND REQUEST FOR FURTHER STUDY FOR THE RIPOGENUS HYDROELECTRIC PROJECT (P- 2572) AND PENOBSCOT MILLS HYDROELECTRIC PROJECT (P-2458)

American Whitewater and Appalachian Mountain Club ("AW/AMC") submit the following comments and requests for additional study pursuant to 18 CFR section 5.15, in response to the April 23, 2023 filing of the Initial Study Report (ISR) for the Ripogenus Hydroelectric Project and Penobscot Mills Hydroelectric Project (FERC Project Nos. P-2572, P-2458) by Great Lakes Hydro America, LLC ("GLHA"). The licensee held an in-person ISR meeting in Millinocket, Maine in which it provided information on the status of the 20 studies required by FERC's May 13, 2022 Study Plan Determination ("SPD").

## Summary and Requests for Additional Study

On October 8, 2021, AW/AMC filed extensive comments on the pre-application and scoping document, as well as submitting three study requests, to collect information needed to develop an understanding of project operations and their impacts on resources to inform the proceedings and compliance with the National Environmental Policy Act. Specifically, AW/AMC requested the applicant complete the following studies: (1) Recreation Facility Inventory, Recreation Use and Needs Assessment, Aesthetics and Reservoir Surface Area Assessment Study; (2) Controlled-flow Whitewater Boating and Access Study; and, an (3) Aesthetics Resources Study. In the Study Plan Determination (SPD), FERC adopted with modifications the study requests of AW/AMC.

In response to the ISR, AW/AMC requests that the applicant address study deficiencies, complete studies not completed in accordance with the Study Plan Determination (SPD), and continue studies where additional information is needed to inform the proceeding. Related to the three studies requested and adopted by FERC with modification, AW/AMC submit the following requests.

1) Pursuant to 18 CFR section 5.15 (d)(1), AW/AMC, request that the applicant complete the Recreation Study consistent with the methodology recommended by FERC in the

SPD. Though the applicant completed a site inventory and condition assessment of formal recreation sites, the SPD clearly states that the methodology must include "provisions for interviews or focus groups with interested individuals representing recreation user groups (e.g. whitewater boaters, anglers), commercial outfitters, and campground owner/operators." The applicant fails to describe any such interviews in the report and fails to note this variance from the approved study plan in the ISR.

As such, it is necessary for the applicant to complete the study in accordance with SPD pursuant to 18 CFR section 5.15 (d)(1), "*Approved studies were not conducted as provided for in the approved study plan.*" Additional comments and inadequacies of the Recreation Study as filed in the ISR are provided herein.

2) Pursuant to 18 CFR section 5.15 (d) & (e), AW/AMC request that the applicant continue to study whitewater boating consistent with the Whittaker Level 2 and 3 methodology, as the Whitewater Boating Assessment has not answered important questions posed in the SPD, specifically the "relationship between stream flow and recreational boating opportunities for a variety of watercraft". The Whitewater Boating Study does not sufficiently identify suitable boatable flow ranges for the West Branch Upper Gorge below Ripogenus Dam and the West Branch below Stone Dam. The applicant notes in the report for the Upper Gorge, for example, that "Flow information is not publicly available for this reach," therefore the report's Suitable Boatable Flow Range can only be accurately determined by a Level 2 and Level 3 Whittaker assessment of on-land and on-water controlled flow studies. The Stone Dam reach, identified as having a Suitable Boatable Flow Range of 700-5,000 cfs, has no publicly available flow information and only two paddlers and one video were referenced in developing the report. The applicant notes in the report that releases from Stone Dam are "typically made by deflating the inflatable dam," which seems to provide an opportunity for water to be made available for paddlers.

   AW/AMC requests that FERC require the applicant to proceed to a Whittaker Level 2 and Level 3 study specifically for the Upper Gorge below Ripogenus Dam and the West Branch Below Stone Dam. Insufficient information was collected during the Level 1 study. The methodology dictates that additional study is needed if a Level 1 study cannot affirmatively answer the question, "Does Level 1 information precisely define flow ranges and potential project effects for each flow-dependent opportunity?" (Whittaker, page 13). Without an accurate understanding of flow ranges and flow preferences for paddling these reaches, additional information is needed to inform the National Environmental Policy Act process.

   In the SPD, FERC specifically notes that "The need for a Level 2 or Level 3 study would be addressed after the first study season. Following the ISR meeting, stakeholders can propose to modify the study plan, or propose new information gathering or studies [sections 5.15(d) and 5.15(e)]." Lacking clarity on whether this request falls under

5.15(d) or 5.15(e), AW/AMC respond to the requirement of 5.15(e), and provide the following responses.

*(1) Any material changes in the law or regulations applicable to the information request;*

There have been no material changes in the law or regulations, though the applicant failed to collect sufficient information to complete a Whittaker Level 1 study.

*(2) Why the goals and objectives of any approved study could not be met with the approved study methodology;*

The study goals and objectives have not been fully answered by the ISR. Specifically, the study fails to achieve the study goals to: "assess the … useability of the four study reaches"; "to identify a range or flows that provide opportunities for whitewater paddlers…"; and "assess the acceptable paddling flows under current and proposed Project operations". These study goals have not been accomplished by the ISR.

*(3) Why the request was not made earlier;*

AW/AMC requested the use of the Whittaker methodology in our study plan request, which defines a stepwise approach to studying whitewater, such that a Level 2 or Level 3 study would be conducted if a Level 1 study cannot adequately inform the proceeding. FERC adopted only a Level 1 study, while articulating in the SPD that a Level 2 or Level 3 would be considered if warranted after the filing of the ISR. AW/AMC request the continued application of the Whittaker methodology by proceeding to Level 2 and Level 3 for the Upper Gorge below Ripogenus Dam and the Stone Dam reach, which is both warranted and necessary to inform this proceeding and consistent with our initial study plan request.

*(4) Significant changes in the project proposal or that significant new information material to the study objectives has become available; and*

The Level 1 study demonstrated that the Upper Gorge and Stone Dam reaches contain would provide significant whitewater boating opportunities if sufficient flow, access, and flow information was provided. New information must be collected to achieve the study goals objectives. Information specific to flow preferences of paddlers is lacking, warranting further study beyond the collection of existing information in the Whittaker Level 1 study.

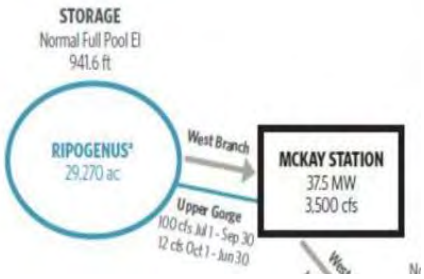
*(5) Why the new study request satisfies the study criteria in § 5.9(b).*

AW/AMC refer to our October 8, 2021 filing of PAD comments and study request, wherein these questions were answered in detail. To further clarify, AW/AMC reiterate that study goals and objectives outlined in our study request and as adopted in the SPD have not been answered by the ISR. Specifically, the study fails to achieve the study goals to: "assess the … useability of the four study reaches"; "to identify a range or flows that provide opportunities for whitewater paddlers…"; and "assess the acceptable paddling flows under current and proposed Project operations". These study goals have not been accomplished by the ISR. The use of existing information is insufficient to meet these study goals.

3) Pursuant to 18 CFR section 5.15 (d)(1), AW/AMC, request that the applicant complete the Aesthetic Study consistent with the methodology recommended by FERC in the SPD. Though the applicant collected data to partially inform a baseline documentation of the scenic views, vistas, riverscapes, and other noteworthy features of the projects, the applicant failed to conduct the study "in consultation with Maine BPL, AW/ATC (sic), the Camp Owners Associations, and other interested stakeholders". AW/AMC specifically requested consultation in our study request and FERC recommended the engagement of stakeholder groups in the SPD, which did not occur in development of the Aesthetics Study.

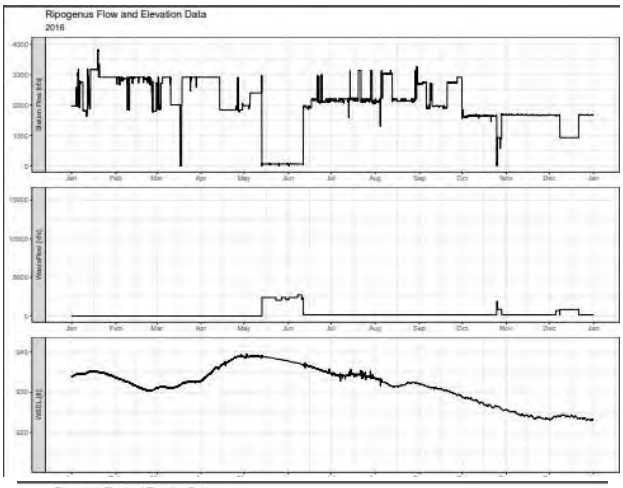
   As such, it is necessary for the applicant to complete the study in accordance with SPD pursuant to 18 CFR section 5.15 (d)(1), "*Approved studies were not conducted as provided for in the approved study plan.*" Additional comments and inadequacies of the Aesthetics Study are provided herein. AW/AMC note that the SPD specifies consultation with "AW/ATC" though we believe this intended to be "AW/AMC".

## Comments on the Initial Study Report

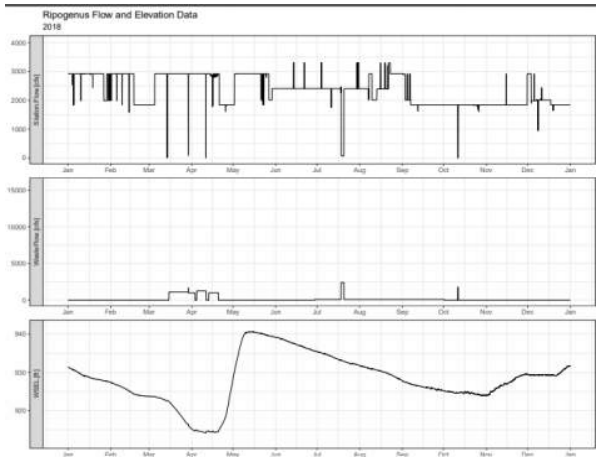


1. Historic Operations Data Assessment Study

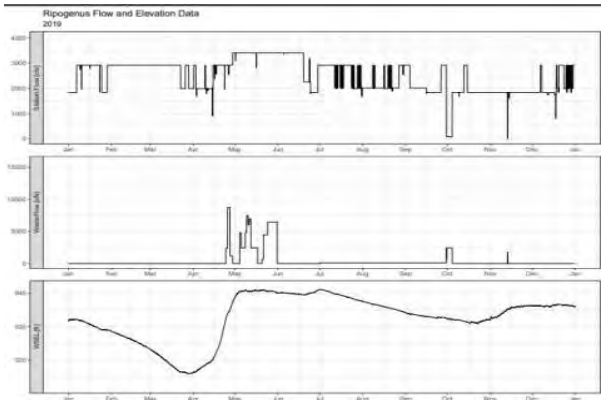
The Ripogenus and Penobscot Mills hydroelectric projects were last licensed in 1996. At the time of the last relicensing, the project provided power to the Millinocket and East Millinocket paper mills. Those paper mills closed in 2008 and 2013, respectively, and the projects were converted to provide power to the electric grid in 2014. Although the project purpose changed in 2014 following the closure of the paper mills, the Water Management Plan, including the required minimum flows to the West Branch Penobscot bypassed reaches and Millinocket Stream, is based on the project purpose of supplying power to the paper mills at the time of the last relicensing. The study does not address historical changes in the timing of generation since the closure of the paper mills and the repurposing of the project,



The licensee's Historic Operations Data Assessment Study includes a system diagram of the Ripogenus and Penobscot Mills projects that identifies project facilities and flow

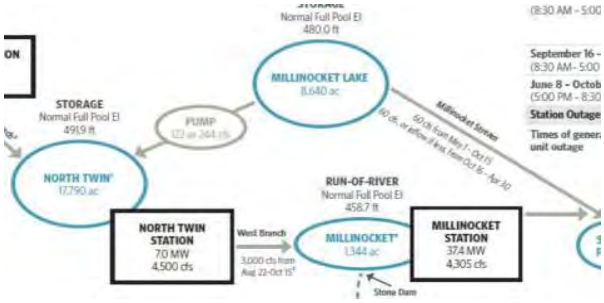


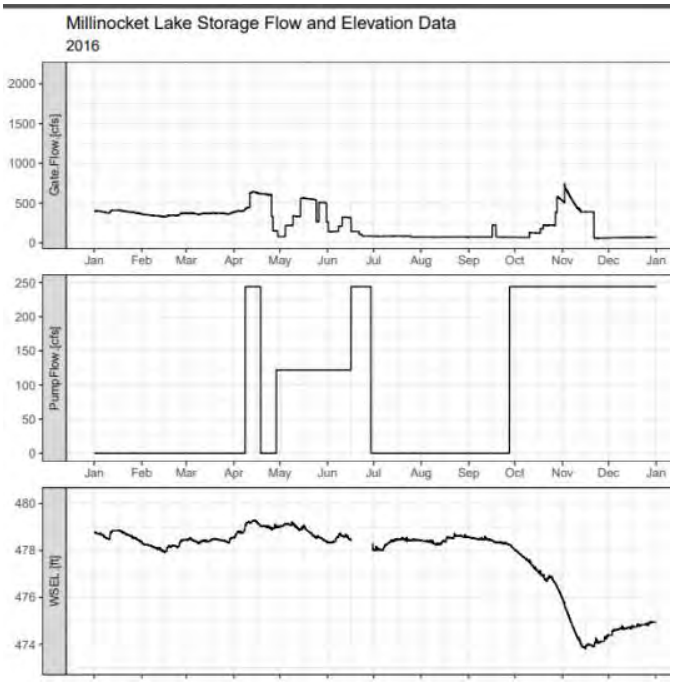
requirements under the current license. The study also summarizes river hydrology and the effects of project operations on impoundments and downstream flows over a 20-year period. Providing aggregate information is of limited use in understanding the effects of project operations, and stakeholders requested that the licensee provide the raw data in Excel format so that stakeholders can provide meaningful comments on the study report. On May 22, 2023, the licensee filed the raw data along with its ISR meeting summary. While the licensee provided hourly flow data, 15-minute interval data is typically provided for USGS gage data and would allow for a more granular analysis that would be useful in evaluating the project impact on other resources. Given the volume of data and the short time allowed for commenting on the ISR according to FERC's relicensing schedule, we reserve the right to provide additional comments on this study once we are able to complete a more in-depth review of the data.



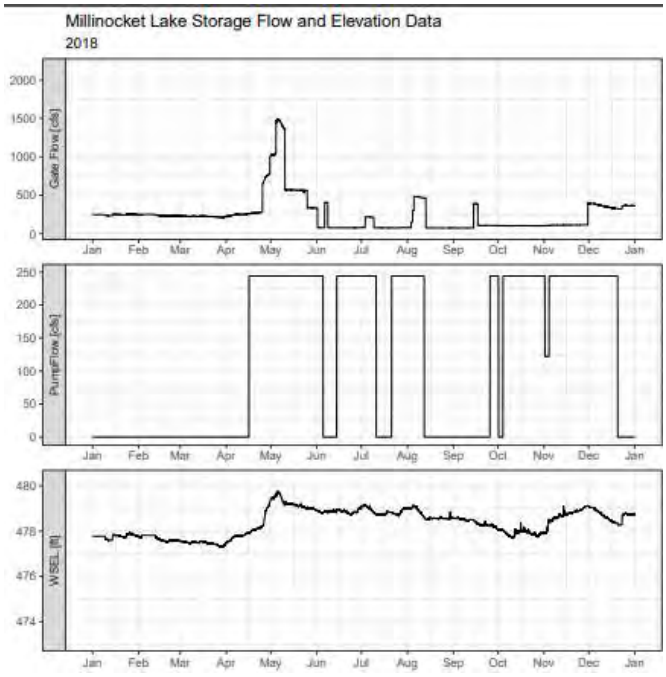
While the system diagram is complex, it's helpful to view the project components separately to better understand the effect of project operations on aquatic and recreation resources. The Ripogenus Dam impounds the West Branch creating a 710,000 acre-foot impoundment that fluctuates by 44 feet and causing negative impacts to Ripogenus Lake, Caribou Lake, Chesuncook Lake, Moose Pond, Brandy Pond, and Black Pond. Project operations at Ripogenus divert flows into a penstock bypassing the natural river channel, leaving .75 miles of the West Branch dewatered except for an unnatural minimum flow of 12-100 cfs when flows are less than the 3500 cfs hydraulic capacity of McKay Station. Under its current license, the licensee is required to release minimum flows at McKay Station ranging from 1000-2300 cfs at different times of day and at different times of year that support power generation, aquatic habitat below McKay Station, and whitewater boating and other recreation.

Project operations at McKay alter flows by impounding and gradually releasing flows on the West Branch. Project operations at McKay adversely affect water quality by raising water temperature and lowering dissolved oxygen in the impounded lakes, reducing sediment transport, harming the littoral zone, and limiting stream access upstream from the dam. Downstream from the dam, the natural river channel between Ripogenus Dam and McKay Station is adversely affected by the inadequate minimum flow and by the loss of naturally variable flows that have an adverse effect on aquatic habitat and whitewater boating use in the Upper Gorge. An examination of historical flow data demonstrates the infrequency of spill below Ripogenus Dam when the impoundment is full and inflows exceed the 3,500 cfs McKay Station hydraulic capacity. Fig. 1, below, shows total spill below McKay Station during low (2016), average (2018), and high (2019) water years.

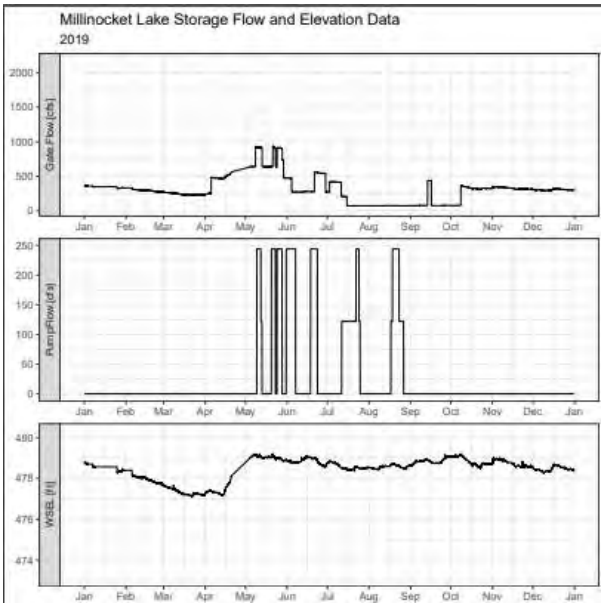




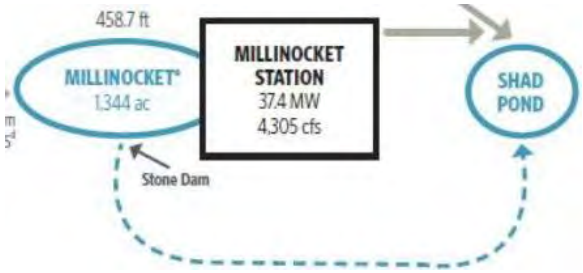
The above tables show that spill below Ripogenus Dam is infrequent even during even the highest water years and is generally limited to the high flows that typically occur at tail end of the spring freshet when the impoundment fills after the annual winter drawdown. The licensee manages the project to maximize generation by lowering the reservoir elevation during the winter to avoid spill — what the study report euphemistically and offensively calls “waste flow”, but which are actually the restored natural flows to the West Branch of the Penobscot River. This



artificial lowering of the impoundment reduces the number of boatable days in the Upper Gorge and beneficial effects of high flows on aquatic habitat.



Below Ripogenus, the Penobscot Mills Project is a bit more complex, but can be better understood by breaking down the flow management into several core components. Millinocket Lake Storage serves as one of several impoundments for the Millinocket Development with a fluctuating impoundment affecting upstream and downstream aquatic habitat. Flows on Millinocket Stream are diverted by Millinocket Lake Dam and then pumped to Ambajejus Lake joining inflows from the Ripogenus Project into North Twin. The pumping station was constructed in 1950 to provide additional water for generation of power for the paper mills. With the demise of the paper mills, the flow diversion and partial dewatering of Millinocket Stream provides power to the grid and profit to the licensee. Lake Millinocket and Millinocket Station essentially function similar to Ripogenus in that flows are diverted by Millinocket Lake Dam through a series of impoundments before flowing into the Millinocket Station tailrace and back into Millinocket Stream.



The effect of this diversion is the partial dewatering of Millinocket Stream leaving only a minimum flow of 60 cfs or less to support aquatic habitat. The flow diversion at Millinocket Dam disrupts river connectivity due to the lack of fish passage, obstructs sediment transport and water quality, and reduces flow variability. The licensee operates two pumps with a combined hydraulic capacity of 244 cfs to pump water from Millinocket Lake to Ambajejus Lake. The pumps typically operate from 16-63 percent of the time throughout the year, with near continuous pumping typically occurring throughout much of the warmer summer months in all water year types, often reducing outflows from 300 cfs down to a meager 60 cfs for much of the year. Since there is no gage on Millinocket Stream, the flow data is based on a calculated flow, so the accuracy of this data cannot be verified.

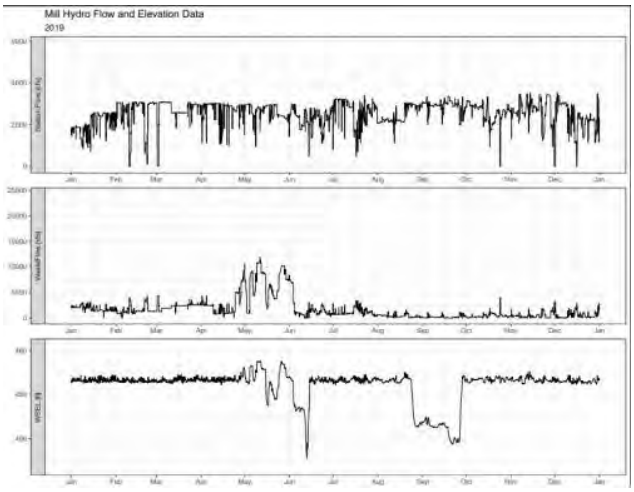
The Millinocket Development also functions as a typical hydropower project with Stone Dam impounding the West Branch of the Penobscot River, a bypassed reach on the West Branch of the Penobscot River below Stone Dam, and a powerhouse at Millinocket Station discharging diverted flows into Shad Pond before rejoining the West Branch at Shad Pond. Under the current FERC license, the bypassed reach of the West Branch has been completely dewatered by the Stone Dam other than minimal leakage or infrequent spillage over the flashboards.



The 1996 FERC license disregarded the environmental consequences of the complete dewatering of the West Branch below Stone Dam based on the economic impact to the paper mills owned by the then licensee, Great Northern Paper. The dewatering of the West Branch below Stone Dam can no longer be justified by the economic impact on Great Northern Paper whose paper mills no longer operate, their crumbling structures marring what would otherwise be a pristine landscape. The dewatering below Stone Dam has disrupted river connectivity, destroyed aquatic habitat, eliminated recreation opportunities, and degraded cultural resources.

Data provided by the licensee in the ISR as well as its subsequently filed Excel file for the Millinocket Station development is either inconsistent with the manner in which the licensee operates the project or is otherwise unreliable.

If accurate, the data shows that the licensee has the capacity to release a full range of flows below Stone Dam notwithstanding its supposed lack of physical ability to do so due to its installation of a bladder gate that blocked access to its operable gates at Stone Dam. The data

graphs, above, depict that the licensee generated variable flows at Millinocket Station while never operating the station at capacity during the three water years shown. At the same time, the graphs show that the licensee maintained a generally stable impoundment and continuously spilled variable flows below Stone Dam. Since the licensee lacks a flow gage at the project and calculated virtual flows based on impoundment level and Millinocket Station generation, the data provided by the licensee appears to be unreliable. The licensee should explain in its response to these comments whether the data provided in this study accurately reflects the flow below Stone Dam, and if so, the reasons for and the means by which it released the flows shown. To the extent that the licensee's data is inaccurate, it should explain the extent to which it relied on this data in the development of the operations model.

2. Operations Model Study

The licensee developed an operations model to simulate both current operations and the impact of alternative modes of operation on generation, reservoir levels, and outflows. The model inputs also included reference gages that simulate project inflows and selected the Seboeis gage (USGS-01029200) and the best reference gage. The Seboeis gage, once adjusted for the drainage area, is useful for evaluating the extent to which the project alters the natural flow regime and causes adverse impacts to aquatic habitat, recreation, and other non-developmental resources. Additionally, the licensee utilized the model to create a baseline against which alternative operating scenarios will be evaluated. While the study endeavors to verify the accuracy of the model against historic operations data, the model results often vary considerably from historic operations.

The licensee elected to utilize the CHEOPS operations model rather than an open-source model such as HEC-RAS that would have provided greater transparency and opportunities for stakeholders to "turn the knobs" on the model to better understand the effect of different scenarios, meaningfully participate in the relicensing process, and better inform FERC's NEPA analysis. Both American Whitewater and FERC raised this concern at the ISR meeting, and FERC appropriately encouraged stakeholders to submit alternative operating scenarios for evaluation utilizing the operations model.

AW/AMC request operations model runs for a variety of scenarios related specifically to flows released from the following locations: 1) Ripogenus Dam; 2) Millinocket Lake Dam; and, 3) Stone Dam. River ecology and recreation on the West Branch of the Penobscot River watershed has been significantly impacted by the projects. The models proposed by our organizations seek to mitigate for the impacts of the projects on our interests and would benefit recreational users.

At the Upper Gorge, whitewater paddlers primarily seek Operations Model Runs that would evaluate the effect of providing scheduled whitewater boating opportunities in the Upper Gorge and increase minimum flows. While the acceptable and optimal whitewater boating flows in the Upper Gorge are not well understood, we request a model run evaluating the effects of providing weekly paddling opportunities in the Upper Gorge during the boating season at a flow

of 1,000 cfs. Additionally, we request that the licensee model a 400 cfs minimum flow in the Upper Gorge. This flow would better support aquatic habitat than the current 100/12 cfs minimum flow. The flow would also ameliorate fish stranding downstream of McKay Station when combined with the estimated 500 cfs released during station outages from McKay, a concern raised by Trout Unlimited. These operations model runs will help inform the relicensing, but should not be considered an exhaustive list or a mitigation proposal.

At Lake Millinocket, we have requested two scenarios that would benefit downstream flows and recreation on Millinocket Stream. Ending pumping operations from Millinocket Lake to Lake Ambajejus for generation at Millinocket Development would restore the natural flow regime to Millinocket Stream benefitting aquatic habitat and supporting recreational boating when sufficient natural flows are present. The current 60 cfs steady state flow release eliminates all natural flow variability. Inasmuch as the flow diversion was based on the power needs of the paper mills, restoring Millinocket Stream to its natural state should be modeled. Additionally, providing weekly scheduled releases of 600 cfs during the boating season would support the demonstrated interest in recreational boating on Millinocket Stream.

Below Stone Dam, the requested operations model runs would provide weekly scheduled whitewater boating opportunities as well as a minimum flow that would support aquatic habitat and a cold-water recreational fishery. While additional study is needed on this river reach, a modeled flow of 2300 cfs would match the whitewater flow releases at McKay Station and would pass these same flows through the West Branch below Stone Dam. Additionally, the licensee should model a 400 cfs minimum flow on the West Branch below Stone Dam to provide sufficient wetted width and WUA as supported by the instream flow study.

American Whitewater and Appalachian Mountain Club submit the following operations model runs:

**Model Run #1**
**Upper Gorge Bypassed Reach Minimum Flow**

This model seeks to increase the minimum flow on the West Branch below Ripogenus Dam

| | Dates | Flow (cfs) released from Development | Remarks | Start Hour | End Hour |
|---|---|---|---|---|---|
| Current | 7/1-9/30<br>10/1-6/30 | 100 cfs<br>None (12 cfs) | Provide 100 cfs bypassed reach flow below Ripogenus Dam from sluiceway or other gate from 7/1-9/30 reduced to 12 cfs from 10/1-6/30 | 24 hours | - |
| Alternative | Year Round | 400 cfs | Provide continuous minimum flow of 400 cfs in bypassed reach below Ripogenus Dam to support aquatic habitat and recreation. Minimum flow would also augment flow in the event McKay Station outage, reducing stranding downstream | 24 hours | |

**Model Run #2**
**Upper Gorge Bypassed Reach Whitewater Releases**

This model run seeks to provide opportunities for scheduled whitewater releases in the Upper Gorge below Ripogenus Dam

| | Dates | Flow (cfs) released from Development | Remarks | Start Hour | End Hour |
|---|---|---|---|---|---|
| Current | None | None | No scheduled whitewater releases are currently required in the Upper Gorge | - | - |
| Alternative | 5/1-10/1 | 1000 cfs | Provide flow of 1000 cfs in the Upper Gorge below Ripogenus Dam for 4 hours one weekend day each week to support whitewater boating in the Upper Gorge and below McKay Station. Flow below McKay Station would remain unchanged from current license requirements. | 1000 | 1400 |

**Model Run #3**
**Millinocket Stream Flow Restoration**

This model run seeks to eliminate pumping from Millinocket Lake to North Twin.

| | Dates | Flow (cfs) released from Development | Remarks | Start Hour | End Hour |
|---|---|---|---|---|---|
| Current | Year Round | 60 cfs or inflow if less | Millinocket Stream inflows are pumped from Millinocket Lake to Ambajejus Lake by two pumps with a combined hydraulic capacity of 244 cfs..Millinocket Lake levels fluctuate 6.2 feet. | 24 hours | 24 hours |
| Alternative | Year Round | All inflow | Restore flows to Millinocket Stream by discharging all inflow from Millinocket Lake Dam, stabilizing lake levels and restoring natural flow regime. | 24 hours | 24 hours |

**Model Run #4**
**Millinocket Stream Whitewater Releases**

This model run seeks to provide opportunities for scheduled whitewater releases in Millinocket Stream

| | Dates | Flow (cfs) released from Development | Remarks | Start Hour | End Hour |
|---|---|---|---|---|---|
| Current | None | None | No scheduled whitewater releases are currently required from Millinocket Lake Dam into Millinocket Stream | - | - |
| Alternative | 6/1-10/1 | 600 cfs | Provide flow of 600 cfs from Millinocket Lake Dam into Millinocket Stream for 4 hours one weekend day each week to support whitewater boating on Millinocket Stream | 1000 | 1400 |

**Model Run #5**

**West Branch Below Stone Dam Minimum Flow**

This model run seeks to establish a minimum flow for the West Branch below Stone Dam

| | Dates | Flow (cfs) released from Development | Remarks | Start Hour | End Hour |
|---|---|---|---|---|---|
| Current | - | None (3 cfs) | Currently there is no minimum flow requirement on the West Branch below Stone Dam | - | - |
| Alternative | Year Round | 400 cfs | Restore flows to the West Branch below Stone Dam by discharging a continuous minimum flow of 400 cfs through new gate structure or powerhouse to benefit aquatic habitat and recreation | 24 hours | 24 hours |

**Model Run #6**

**West Branch Below Stone Dam Whitewater Releases**

This model run seeks to provide opportunities for scheduled whitewater releases in the West Branch below Stone Dam

| | Dates | Flow (cfs) released from Development | Remarks | Start Hour | End Hour |
|---|---|---|---|---|---|
| Current | None | None | No scheduled whitewater releases are currently required from Stone Dam into the West Branch | - | - |
| Alternative | 5/1-10/1 | 2300 cfs | Provide flow of 2300 cfs from Quakish Lake over Stone Dam for 4 hours one weekend day each week to support whitewater boating on the West Branch below Stone Dam | 1000 | 1400 |

3. Water Quality Study

The Water Quality Study assessed project impacts on water quality in the impoundment and riverine reaches. Regarding the Riverine Aquatic Habitat Assessment of the Upper Gorge, the study failed to achieve the study goal to determine if existing baseline minimum flow conditions provide aquatic habitat that meets MDEP's hydropower guidance.

The study purports to evaluate the reach to determine zone of passage conditions for adult resident fish (e.g., landlocked salmon) at the two seasonal minimum flows. While the study evaluated the minimum depth at its three chosen transect locations, the study did not assess whether the minimum flows provided a continuous zone of passage throughout the Upper Gorge. Given the high gradient in the Upper Gorge and the lack of any minimum flow whatsoever for nine months of the year with the exception of an estimated leakage flow of 3 cfs, the study's conclusion that the flows provide suitable aquatic habitat defies both logic and laws of physics. Instead, for most of the year the reach contains a series of disconnected pools separated by a rocky substrate that fails to provide landlocked salmon with a continuous zone of passage in the Upper Gorge. The USFWS' standard protective ABF recommendation of 0.5 cfs/square mile of drainage area (1422 cfsm) would require a minimum flow of 711 cfs in the Upper Gorge.

The study also fails to adequately address whether the minimum flow provides sufficient wetted width in the Upper Gorge. As noted in the report, the study requested by MDEP was to assess whether the existing minimum flow maintains three-quarter wetted cross-sectional area, as defined in Chapter 581 (5) of MDEP's regulations relating to water quality evaluations. Neither the study's selected transects nor the other methods used by the licensee demonstrate that the existing minimum flow meets this standard,

At Millinocket Stream, the study compared existing minimum flow conditions to the estimated bankfull conditions (% cross sectional area). The results of this study showed that the existing 60 cfs minimum flow release provides approximately 36 to 54 percent of the cross-sectional area of the bankfull channel, demonstrating that the project fails to adequately protect the wetted stream width at Millinocket Stream.

Regarding the reach below Stone Dam to Shad Pond, this section of the Penobscot River has a lowered water classification of Class C due to the complete dewatering of the reach by the licensee other than the backwatering from Shad Pond and the rare spill event. Any suggestion that this dead river reach meets even the reduced classification protective of aquatic life or recreation is nonsensical as this reach contains stagnant and disconnected pools under normal operating conditions. The licensee, appropriately, does not characterize the current dewatered state of the West Branch below Stone Dam as meeting the wetted width or minimum depth criteria. The report provides information on flow levels at its two selected transect locations demonstrating that the current flow is inadequate. Additionally, the zone of passage analysis only models flows up to 100 cfs rather than modeling higher flow levels. The modeling shows that a flow of 100 cfs provides only a narrow zone of passage in these two zones.

4. Instream Flow and Habitat Downstream of Stone Dam Study

This study assessed the adequacy of minimum flows for a cold-water fishery downstream of Stone Dam. Presently, there is no cold-water fishery due to the dewatering of this section of the West Branch by the licensee. The present lack of flows fails to provide adequate wetted width or depth required for adult Brook Trout or Landlocked Salmon according to the study. While different life stages and fish species require different minimum flows, providing a minimum flow of at least 400 cfs would be necessary to maintain three-quarter wetted cross-sectional area or provide a weighted usable area (WUA) of at least 80 percent. The study further found that maximum suitable habitat for adult Brook Trout and macroinvertebrates requires a minimum flow of 700 cfs.

The study reanalyzes data from the 1987 IFIM conducted at the time of the last relicensing. The IFIM evaluated flows of 420 and 700 cfs releases from a 52-foot-wide mechanically operated log sluice atop the center section of Stone Dam. Since that time, the licensee installed a 428-foot wide, 2-foot 9-inch-high Bridgestone rubber inflatable dam on the river left section of the dam. The licensee states in the PAD the following:

> Air is supplied to the rubber dam for inflation through a fitting in the abutment of the dam that is connected to two high capacity air blowers. Inflation or deflation of the rubber dam may be done in one of two modes: Manual or Automatic. Remote monitoring and control from Brookfield's National System Control Center (NSCC) is the normal mode of operation. Instead of gate operation, the NSCC operator remotely inflates or deflates the rubber dam to pass the appropriate flows. Flows from the dam enter the 4.5-mile-long Back Channel before flowing into Shad Pond.

It is unclear when FERC amended the license or when the licensee installed the rubber inflatable dam. The licensee asserts that the installation of the inflatable dam prevents access to the mechanical gate structure in the center section that previously allowed it to provide a controlled flow release from Stone Dam. While the licensee claims that it is now unable to provide controlled flow releases from Stone Dam due to the installation of the rubber inflatable dam, that does not appear to be correct. With an upstream monitoring system detecting varying water levels, the automatic control system adjusts the air pressure in the dam to maintain the desired water level. In any event, the licensee knew or should have known that it would be required to restore flows to the West Branch below Stone Dam in the upcoming relicensing and should have maintained the ability to do so either using current or new gate structures. To the extent that the licensee's own modifications limited its ability to control flows, that limitation is of its own doing and should be addressed in this relicensing.

5. Recreation Study

The licensee's Recreation Study fails to provide FERC with sufficient information to evaluate project impacts on recreation opportunities in the project boundary and in areas affected by project operations. By limiting the geographic scope of the study to FERC-approved

recreation sites, the study omits informal recreation sites that provide in some cases the only river access to waters in the project boundary or are otherwise necessary to engage in recreational activities in the project area.

In the Upper Gorge, the study fails to address the adequacy of trails leading to the water below Ripogenus Dam that is used by boaters and anglers. The path down to the river is unmarked and difficult to discern, very steep, overgrown, and loose posing a safety risk especially for those shouldering a whitewater kayak. At Millinocket Stream, the access is unmarked, there is inadequate parking, and difficult river access. At Stone Dam, there is no clearly marked parking area across Quakish Lake, there is no easy egress at Stone Dam, and no land access to Stone Dam is provided. These areas are all used during spill events when flows are restored to these river reaches; however, the difficult access and lack of real-time flow information inhibit recreational use. To assess project effects on this recreation opportunity, the licensee needs to expand the geographic scope of the study to include informal recreation access areas identified by stakeholders.

While the study purports to assess recreation facilities, access, and use at formal recreation areas, the study is deficient in several important respects. Comments by stakeholders at the ISR meeting raised concerns about the McKay Station river access. According to rafting outfitters, the rafting put-in needs improvement to provide safe river access. Additionally, there is no sanitation at the lower access area where rafters are dropped off as the only portable sanitation unit is locked. There is no signage directing rafters to summit the steep access road to locate the toilets at the upper parking area. The access road to the lower drop off location is available only to commercial outfitters but not other boaters. Egress from the West Branch below McKay should also have been evaluated as part of this study. Instead of providing an objective assessment, the study inaccurately concludes, “All of the facilities and amenities associated with this Project recreation site were in good condition.”

The study also included random spot counts at the various formal recreation sites. This methodology tends to undercount actual recreation usage that is concentrated at certain times of day, certain days of the week, and certain days of the year. With regard to whitewater boating, the majority of outfitters launch according to a schedule rather than at random times, and individual paddlers tend to access the river at certain times of the day, likely resulting in an undercount of recreational users. While there is data from the State of Maine on commercial outfitters, there is no corroborating data on use by individual boaters. Parking can also be a poor indicator of usage as boaters tend to carpool and shuttle vehicles to boater take-out locations. It is likely that the study significantly undercounted actual whitewater boating usage.

We acknowledge that while the Whitewater Boating Study did address boating access to a limited extent, access concerns weren’t adequately addressed in either the recreation or whitewater boating study. In the Upper Gorge, for example, the study merely states that access is discouraged because of the steep embankment, and Stone Dam access was ignored entirely. While the licensee compiled the results of paper and online surveys, it collected and analyzed only 34 surveys at all of the Penobscot Mills recreation sites, none of which were collected at Millinocket Stream and none at Stone Dam. An additional study season will be required to collect additional recreation study data.

The study also failed to perform qualitative data collection. FERC's Study Plan Determination recommended that the study include the following methodology:

> Maine BPL, AW/AMC, the Camp Owners Associations and Maine TU request that GLHA's recreation study include qualitative (interview) component to garner input from organizational representatives. Interviews or focus groups with recreation user groups and commercial outfitters are a standard practice in hydropower relicensing proceedings, and would allow for robust understanding of recreation use, needs and interests in the Projects' areas. When combined with the facility assessment reports and quantitative data collected as part of the user surveys, such qualitative information can be useful in developing a licensing proposal that meet the needs of various users [sections 5.9(b)(5) and 5.9(b)(6)]. Therefore, we recommend that GLHA add provisions for interviews or focus groups with interested individuals representing recreation user groups (e.g., whitewater boaters, anglers), commercial outfitters, and campground owner/operators. Adding this component would allow for information to be obtained on the informal and formal recreation sites at the Projects [section 5.9(b)(5)].

Despite FERC's recommendation that the study include qualitative data collection as requested by Maine BPL, American Whitewater, Appalachian Mountain Club, the Camp Owners Associations and Maine Trout Unlimited, the licensee declined to do so and failed to make even a minimal effort to reach out to the stakeholders requesting this study component. Given this omission, the licensee should be required to complete and revise this study report.

6. Whitewater Boating

American Whitewater and Appalachian Mountain Club requested that the licensee study project effects on whitewater boating opportunities on four river reaches in the project boundary: 1) Upper Gorge between Ripogenus Dam and McKay Station; 2) Below McKay Station to Debsconeag; 3) Millinocket Stream below Millinocket Lake Dam; and, 4) West Branch between Stone Dam and Shad Pond. The intent of the study is to identify the acceptable and optimal flow ranges for whitewater boating by individuals currently or potentially utilizing these river reaches under current or alternative modes of operation, evaluate the adequacy of put-in and take-out locations and the need for access improvements, and identify flow information needs that would support whitewater boating use. FERC-approved whitewater boating studies routinely follow the standard methodology as described in Whittaker et al., in "*Flows and Recreation: A guide to studies for river professionals"* (2005). This methodology is designed to assess the presence, quality, and preferred flow ranges for river-based boating resources in a stepwise manner. The process steps are generally 1) desktop analyses, 2) on-land feasibility assessment, and/or on-water single flow assessment, 3) on-water multiple flow assessment.

In its Study Plan Determination, FERC required the licensee to conduct a Level 1 desktop analysis of the four river reaches identified in the study request and required the submission of a study modification request if further study was warranted. The study methodology, however, is designed as a three-phase process with off-ramps where sufficient information is obtained at an earlier stage that makes further study unnecessary. By bifurcating (or trifurcating) the study

methodology, FERC deviated from Whittaker protocols and placed an unnecessary burden on stakeholders to submit a study modification request following FERC's study modification criteria. The need for additional study, however, is defined by the protocols themselves, such as when the desktop analysis fails to identify acceptable and optimal flow ranges.

Determining whether a Level 2 or Level 3 whitewater boating assessment is required turns on the answer to several questions under the Whittaker protocols:

- Are there flow-dependent recreation opportunities on the river segments?
- Are flow-dependent opportunities affected by project operations?
- Are flow-dependent recreation opportunities "important" relative to other resources or foregone power generation? If certain recreation opportunities will not be considered when determining project operation decisions (e.g., if agencies and stakeholders agree that flow releases will be primarily driven by biological needs for an endangered species), more detailed information about flows may be unnecessary, and Level 1 information may be sufficient (assuming it documents stakeholder and agency agreement about this evaluation).
- Does Level 1 information precisely define flow ranges and potential project effects for each flow-dependent opportunity? For example, flow ranges for a commonly boated whitewater reach may be sufficiently well-known and agreed upon, and there may be no need for additional study.

Where a flow-dependent recreational activity lacks precise information about flow needs or project effects, a Level 2 or Level 3 flow study is typically required. Conversely, where a river reach is well known and existing information is sufficient to evaluate the reach, further study may be unnecessary.

At the Ripogenus and Penobscot Mills projects, there is no disagreement that whitewater boating opportunities are flow dependent and directly affected by the licensee's facilities and operations that divert and alter flows that are used by whitewater boaters. Additionally, whitewater boaters have identified these river reaches as important and there are no overriding resource needs that would prevent further consideration of recreational boating. The need for a Level 2 or Level 3 study depends on whether existing information is sufficient to precisely define flow ranges and potential project effects. Of the four river reaches on the West Branch, sufficient information was compiled on two of the four river reaches (McKay Station and Millinocket Stream); however, additional study phases are necessary on two others (Upper Gorge and Stone Dam).

The most well understood reach on the West Branch is the reach between McKay Station and Debsconeag. Since the last license issuance in 1996, more than 250,000 recreational boaters have been guided down this section in rafts by commercial outfitters. The West Branch below McKay Station is the arguably the most renowned whitewater river in the northeast, its closest comparable river reach being the Gauley River in West Virginia. The upper section below McKay features a series of Class III – V rapids through the Penobscot Gorge and Cribworks sections to Big Eddy. This section of the West Branch is known for its powerful hydraulics, waterfall drops, stunning views of Mount Katahdin and frequent wildlife sightings. The 15-mile

reach down to Debsconeag provides both rafters and individual boaters with an unequaled boating opportunity in the region.

The current FERC license requires that the licensee release daytime flows ranging from 1800-2300 cfs between May 1 – October 1 with flows varying within this range depending on the day of week and hydrologic conditions. This flow range is well utilized by both individual boaters and commercial outfitters. The last relicensing assessed the following flows below McKay Station: 1,700-1,999 cfs; 2,000-2,199 cfs; 2,200-2,399 cfs; 2,400-2,599 cfs; 2,600-2,799 cfs; 2,800-2,999 cfs, and 3,000+ cfs. Over 90 percent of respondents were "very satisfied" or "extremely satisfied" with all but one of the flows provided (2,000-2,199 cfs)2 (GNNC 1991). Based on the information available from the last relicensing and surveys completed during the Level 1 study, we believe existing information provided by commercial outfitters and individual boaters is sufficient to understand acceptable and optimal flow ranges. Consequently, further study is unnecessary; however as previously noted, river access concerns at McKay have not been adequately addressed in the study report.

Millinocket Stream between Lake Millinocket and the Millinocket Development tailrace was also evaluated in the study report. At the time of the last relicensing, little was known about this reach and only minimal anecdotal information was available and no controlled flow study was conducted. Over the past two boating seasons, local paddlers have hosted the Millinocket X-Stream Canoe Race on the reach below Lake Millinocket Dam with the support of the licensee. The race draws nearly 100 participants and spectators and paddlers navigate the Class II-III rapids including Locomotive Rips (Turtle Pits Rapids) and other less challenging sections. In 2022, the licensee released a flow of 530 cfs for the canoe race. In surveys and information collected from participants, the 530 cfs flow level was regarded as acceptable but less than optimal due to the shallow depth and exposed rocks in places. In 2023, the licensee released a flow of 728 cfs for the canoe race. While this level was regarded as more challenging for some participants, the flow was regarded as optimal by most race participants. Surveys completed by participants in the Millinocket X-Stream Canoe Race demonstrate that Millinocket Stream is a highly valuable recreational resource under appropriate flow conditions. At the time that AW/AMC filed their initial study request little was known about this reach; however, information collected over the past two years during the canoe race is sufficient to evaluate the recreation potential of this river reach, and no further study is necessary. As with McKay Station, the study should be updated to include a more complete assessment of river access. Additionally, the study should address the flow information needs at Millinocket Stream.

While we agree that a Level 1 under the Whittaker protocols is sufficient to evaluate the McKay Station and Millinocket Stream river reaches, the data and analysis presented in the Whitewater Boating Study is insufficient to evaluate the whitewater boating resource in the Upper Gorge and Stone Dam river reaches.

The Level 1 whitewater boating study contains useful but limited information about the Upper Gorge between Ripogenus Dam and McKay Station. While the study characterizes the reach as short, the value of this reach should be assessed as an extension of the reach below McKay Station as boaters accessing the Upper Gorge would typically continue down past McKay Station. The study report characterizes the Upper Gorge as containing continuous Class

IV/V rapids that would substantially expand the number of challenging and desirable river features at Ripogenus. But for the licensee's flow diversion for generation, boating in the Upper Gorge would be available on a daily basis throughout the boating season. Viewed in this context, the Upper Gorge contains important flow-dependent whitewater boating opportunities that are greatly diminished by project operations.

The need for further study in the Upper Gorge turns on whether Level 1 information precisely defines flow ranges and potential project effects on whitewater boating opportunities. While the study included interviews with 10 individuals who had previously boated the Upper Gorge, the information provided on preferred flow levels was not sufficiently precise to identify minimum and optimal flow levels. Responses provided from those interviewed ranged from 400-5,000 cfs. While the report suggests that a flow of 1,000-1,500 cfs provides a minimum flow and a flow of 2,000-3,500 cfs provides an optimal flow, these are general flow estimates lacking specific dates to confirm the accuracy of these estimates. The lack of a USGS gage at the project makes estimating the flow in the Upper Gorge difficult. Flows shown at McKay reflect the station flow readout, but do not indicate the split between generation and spill.

For this reason, the minimum and optimal flow estimates in the study report are insufficient and proceeding to Level 2/3 is necessary to inform the relicensing process; however, this information is useful for identifying flow targets for the Level 2/3 study. The Level 1 study also failed to adequately evaluate current and alternative access to the Upper Gorge and flow information needs.

The licensee also endeavored to assess whitewater boating on the West Branch between Stone Dam and Shad Pond; however, there is little information available on this reach and the only meaningful information collected by the licensee in this study consisted of interviews with two individuals who previously boated this reach on 2 occasions in 2022. The two boaters estimated the flow levels on those occasions at 3,000 and 5,000 cfs; however, the reach has no flow gage and the dates on which they boated the reach is unknown. At best, the estimates given by two individuals boating at a single flow are anecdotal, unverified, and speculative. The "study" was unable to identify acceptable and optimal flow levels across a range of flows and

only characterized a single river feature – Grand Falls – in the reach. While the study lists a flow range of 700-5000 cfs based on these two interviews and perhaps a minimum flow of 1000-2000 cfs (a flow that neither of those interviewed actually boated), these flow ranges lack any meaningful support. What is clear, however, is that the West Branch below Stone Dam would provide valuable whitewater boating if sufficient flow was available, access improved, and real-time flow information provided. The study failed to evaluate current and alternative access or flow information needs.

At the time of the Initial Study Report Meeting, several boaters including a representative from American Whitewater boated the reach below Stone Dam on May 3, 2023. At that time, the inflatable gate was deflated and water was spilling over the flashboards. This section of the West Branch is boatable at that level by paddlers with advanced skills. The boaters accessed the river below Stone Dam after a long flatwater paddle across Quakish Pond and then climbing out of the channel at Stone Dam. All paddlers judged the reach to be of high quality with continuous rapids and a more challenging drop at Grand Falls. Paddlers then proceeded to a takeout further down in Shad Pond across flatwater. The licensee estimated that the flow on that date was approximately 8,000 cfs.

7. Aesthetics Study

American Whitewater and Appalachian Mountain Club requested that the licensee perform an aesthetics resource study to evaluate the impact of the project facilities and operations on the surrounding environment. This information is necessary for FERC to complete its environmental analysis. In its Revised Study Plan, the licensee proposed to use photo and video documentation rather than conduct an on-site assessment of aesthetic impacts as is typically done. Relying on photo/video documentation rather than on-site observation is of little value because it limits the assessment to a visual observation from a single perspective, omitting a more complete evaluation of the impact of the project on the landscape. Nevertheless, FERC approved the study plan with modifications that include a recommendation for using an interdisciplinary team of representatives from GLHA and stakeholders' groups, stating, "The Aesthetics Study should be conducted in consultation with Maine BPL, AW/ATC (sic), the Camp Owners Associations, and other interested stakeholders."

The licensee declined to follow FERC's recommendation that the study should be conducted in consultation with stakeholders. Instead, the licensee self-evaluated a series of photos taken from its self-selected locations, and unsurprisingly, arrived at the self-serving conclusion that the Ripogenus and Penobscot Mills Projects have high aesthetic value under current operations. Essentially, the licensee is presenting its view that the project has no adverse aesthetic impact under baseline conditions, and since it is proposing no operational changes, there is no need for stakeholder engagement in this study. As conducted by the licensee, the Aesthetics Study provides little useful information that would inform FERC's environmental analysis and the study should be redone following FERC's Study Plan Determination.

8. Environmental Justice

The Environmental Justice Study was requested by the Penobscot Indian Nation and FERC to identify Environmental Justice communities located within the study area and evaluate potential effects of continued operation and maintenance of the Projects on identified Environmental Justice communities. Given the remote and sparsely populated location of most project facilities, the 1-mile study area is overly narrow. The geographic area should address project effects that were not captured using the study methodology. Specifically, the study should address project effects on the Penobscot Indian Nation and other indigenous groups and individuals. These effects include traditional cultural uses such as fishing in project waters in the dewatered section of the West Branch below Stone Dam to Shad Pond. Inexplicably, the study failed to conduct any outreach to the Penobscot Indian Nation who requested the study or engage other stakeholder groups to obtain information on project effects on identified Environmental Justice communities. The study is also deficient in that the mapping and sensitivity receptors was based only on potential impacts from any potential project related construction activities while ignoring project related effects from current operations such as the dewatering of the West Branch below Stone Dam. The licensee should revise the study report by conducting appropriate outreach and documenting the effect of current and future operations on Environmental Justice communities as requested.

Summary

While the licensee's Initial Study Report provides information on its progress in completing studies required by FERC's Study Plan Determination, it is unclear which of these reports the licensee considers completed and which are a work in progress. We regard each of the studies discussed here as incomplete, as follows:

- Historic Operations – Stone Dam flow data is unreliable and does not reflect the licensee's current operations.
- Operations Model – AW/AMC have provided a preliminary list of operations model runs that provide alternative modes of operation to address project effects.
- Water Quality – The study report needs to address whether minimum flows meet wetted width and provide a continuous zone of passage in the Upper Gorge and at Stone Dam. Higher minimum flow levels should be modeled.
- Instream Flows Below Stone Dam – Provide information on the ability of the project to release controlled flows from its inflatable dam and, if necessary, provide information on alternative means of providing instream and recreational flows below Stone Dam
- Recreation – Evaluate the adequacy of informal access locations in the Upper Gorge, Millinocket Stream, and Stone Dam river access points. Assess the adequacy of the McKay Station access based on comments received from recreational stakeholders addressing the put-in and sanitation. Identify and evaluate egress locations used by boaters below McKay Station.

- Whitewater Boating – Complete Level 2 and of necessary Level 3 study of Upper Gorge and Stone Dam river reaches including an analysis of current and alternative river access and flow information needs.
- Aesthetics – Consult with stakeholders on the Aesthetics Study as recommended in FERC's Study Plan Determination.
- Environmental Justice – Outreach to the Penobscot Indian Nation for information on project effects on traditional cultural uses by indigenous groups. Expand the geographic scope of the study and sensitive receptors to document project effects under current operations.

## Conclusion

We respectfully request that the licensees for the Ripogenus Hydroelectric Project and the Penobscot Mills Hydroelectric Project update the draft studies incorporating the feedback herein, and complete the following studies by either continuing studies consistent with the approved SPD methodology or to continue to further study where study goals and objectives have not been achieved, including: (1) Recreation Facility Inventory, Recreation Use and Needs Assessment, Aesthetics and Reservoir Surface Area Assessment Study; (2) Controlled-flow Whitewater Boating and Access Study; and, (3) Aesthetics Resources Study. Completing these studies as described herein by AW/AMC will provide FERC with sufficient information to complete its NEPA analysis of project impacts to determine appropriate license conditions that are protective of recreation values and mitigate project impacts. Thank you for considering these comments.

Respectfully submitted this 6th day of July, 2023

**Via online submission to: http://www/ferc.gov**

Subject: **Comments of Maine Council of Trout Unlimited on the Initial Study Report for the Ripogenus Project (P-2572) and the Penobscot Mills Project (P-2458)**

Dear Secretary Bose:

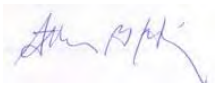
On behalf of its six chapters and over 2,000 members, Maine Council of Trout Unlimited (TU) submits these comments on the Initial Study Report (ISR) for the Ripogenus Project (P-2572) and the Penobscot Mills Project (P-2458) filed for Great Lakes Hydro America, LLC by Brookfield Renewable ("Brookfield" or "Applicant") dated April 24, 2023.[1] This filing also references the Report of the ISR Meeting[2] held May 2 through May 4, 2023 in Millinocket, ME.

The amount of information contained in these reports is considerable, and for clarity and ease of reference, following our general comments, specific TU comments will be organized as a series of appendices corresponding to those in the ISR. Comments regarding the hourly flow data supplied by Brookfield with the ISR are included with Appendix A.

**General Comments**

Taken together, the Ripogenus and Penobscot Mills relicensings reflect over 108,000 kw of generation capacity making this the largest relicensing effort in the state of Maine in terms of electricity production by a large margin. The waters and surrounding habitat affected by these relicensings are of equal stature. The land-locked salmon fishery below Ripogenus Dam is sustained by naturally spawned fish and nationally known for its quality. With Maine's highest mountain nearby, Ripogenus Gorge below the dam is Maine's most spectacular gorge. The waters of the Penobscot Mills Project are also important in their own right and should play a part in the restoration of currently dewatered sections of the West Branch of the Penobscot River to provide traditional waterways and sustenance fisheries to the Penobscot Indian Nation (PIN) that have been so long promised but not delivered.

**Year-one studies have not provided the information required to make informed decisions on the terms and conditions of a new license.** Change of project ownership has resulted in changes to the way the projects are operated, starting at and most affecting the Ripogenus Project and extending downstream to Penobscot Mills Project. In a number of cases, studies modified in year one did not provide the information they were intended to provide or served to underline the need for additional studies. Additional information is needed to limit the drawdowns to the Ripogenus-Chesuncook Reservoir and to peaking operations being conducted at McKay Station. From McKay Station to Stone Dam, the watershed has been extensively modified, and how to optimize project operations so as to



[1] Great Lakes Hydro America, LLC, Initial Study Report for the Ripogenus (FERC No. 2572-133) and Penobscot Mills (FERC No. 2458-247) Hydroelectric Projects dated April 24, 2023.
[2] Initial Study Report Meeting Summary for the Ripogenus Hydroelectric Project (FERC No. 2572-133) Penobscot Mills Hydroelectric Project (FERC No. 2458-247) dated May 22, 2023.

provide the best balance of between electrical power generation and the other uses including fishing, recreation (especially whitewater), aesthetics, and habitat must be found. Specific comments in the appendices will identify specific information needs and present them in accordance with the FERC process.

**Conclusion**

Maine TU Council appreciates the opportunity to provide these comments on these important projects and hopes that the Commission will act to acquire the information needed to enable the Commission to balance project harms and benefits.

Respectfully,

Stephen G. Heinz
Maine TU Council FERC Coordinator

**Historic Operations Data Assessment Study**

**General Comments**

The study does not work with the Historic Operations Data Assessment Study and Operations Model Study to inform the relicensing as intended by the SPD:

> "GLHA would use the existing operations information, along with GLHA's proposed Water Quality Study, Historical Operations Data Assessment, and Operations Model, to assess the Projects' effects on the hydrology in the West Branch and mainstem Penobscot River [section 5.9(b)(4)" [SPD, page B-42].

The study does not provide details of why the Ripogenus-Chesuncook Impoundment was so severely dewatered during the summers of 2020 and 2021.

It should also be noted that the possible license violation reported by TU [TU letter dated May 12, 2022, Subject: Maine Council of Trout Unlimited Comments on the Minimum Flow Excursion Report dated April 28, 2022 for the Ripogenus Project (P-2572)] is still under active investigation by FERC Compliance: "Commission staff are actively working on this proceeding, and response has not yet been issued regarding this matter." [email Andrea Claros to Steve Heinz RE: Pending West Branch Possible License Violation dated June 8, 2023]

**Specific Comments**

Page A-1 The study does not effectively meet its objectives:

> "The goals and objectives of the study are to compile relevant historic operations data for the Projects to allow stakeholders to better understand historical operations of the Projects and associated water management objectives in support of the relicensing of the Projects."

The information contained in the ISR does not do that. How flows are managed for the Ripogenus Project remain unknown and explained by Brookfield as controlled by use of the CHEOPS model, a proprietary 'black box.' This cannot be used as rationale for avoiding informed discussion of how the projects are actually operated.

The study uses the term "waste flow" to label all non-station flows. This includes fishing flows of 100 cfs released using the sluiceway that are fishing flows. Another term should be used.

The study does not answer key questions: why was the Ripogenus-Chesuncook drawn so far down in both 2020 and 2021? Why are peaking operations being conducted as indicated by the attached study?

TU requests OPs Model runs documenting the inputs used to determine McKay Station flows including Ripogenus - Chesuncook Impoundment level elevation and a detailed description of the information used to determine the target impoundment levels:

1. October 16, 2019, December 20, 2019, March 4, 2020
2. October 16, 2020, December 20, 2020, March 4, 2021

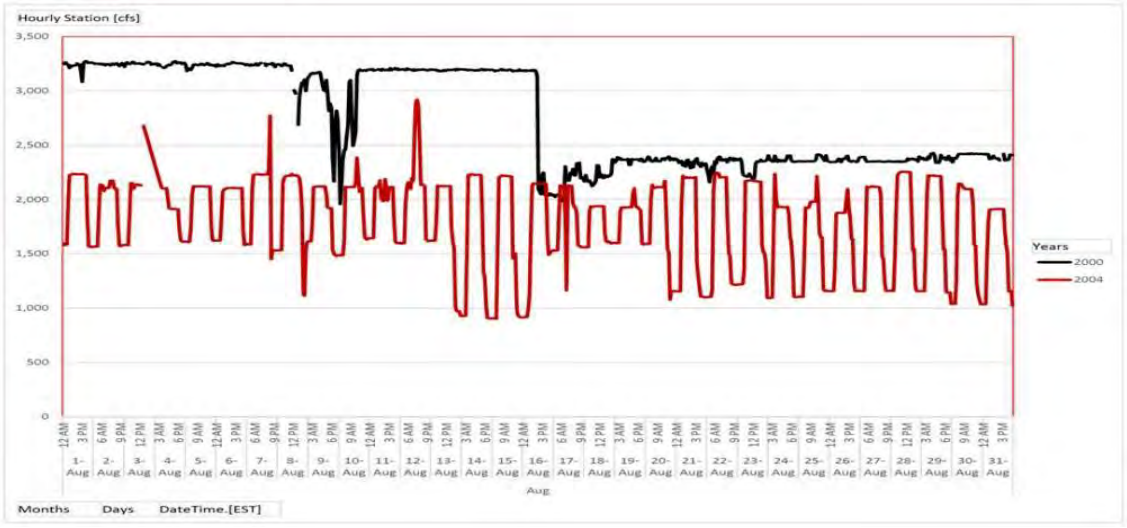
3. October 16, 2021, December 20, 2021, March 4, 2022

October 16, 2021 was when Brookfield reduced spawning/incubation flows to 1100 cfs, March 4, 2022 was when they further reduced them to 800 cfs, December 20 is a rough mid-point. [Brookfield letter dated April 28, 2022, Ripogenus Project (FERC No. 2572-ME); Minimum Flow Excursion] The CHEOPS model alone cannot explain why in the first two timeframes, Brookfield made no effort to fill the reservoir while in the last timeframe it obviously did.

Page A-27 "Over the 23-year period, the Ripogenus impoundment was refilled to or near full pond elevation by late spring for 17 of the 23 years. The 6 years in which the impoundment elevation was not refilled to or near full pond elevation occurred during dry water years in 2001-2004, 2015-2016, and 2021 (Figures 7 and 8)." It is acknowledged that impoundment levels were unacceptably low during the summer of 2020 as well. Over time, it has become increasing difficult to refill the impoundment. A more aggressive approach to water management is needed. One was taken to full the reservoir over the winter of 2021 to 2022.

Page A-33 The figures showing hourly McKay Station flows based on generation data show flows of 4000 cfs, especially Figure 12 below. These exceed the 3500 cfs hydraulic capacity of McKay Station [Pre-application Document dated June 11, 2021, page 4-14. When queried at the ISR Meeting, the Brookfield response was the flows were not completely accurate and a range of variability was not available. This continues to cast doubt on the results of the analysis.

**Figure 12. Estimated hourly flows from McKay Station, 2000-2010**



Page A-60 “The Ripogenus and Penobscot Mills Projects are operated as a combined system using the same system-wide rule curve as described above that has been used since the 1970s.” This does not explain how the Ripogenus-Chesuncook Impoundment was dewatered during the summers of 2020 and 2021 with any specificity, or aid in determining how this might be avoided in the future.

**Hourly Flow Data Comments**

The time delay between the request for the flow data and its submission by Brookfield underlines the need for a USGA flow gage and impoundment level gauge be installed for the Ripogenus Project. The flow gauge should be located immediately below Ripogenus Gorge in the Little Eddy vicinity.

It has been an open issue if project operations have changed since project ownership passed from Great Northern Paper. Increased peaking was reported by MDIFW in its PAD comments: “In addition, there is concern that the West Branch of the Penobscot River below McKay Station is managed as more of a peaking operation with flows exceeding 3,000 cfs during the day and 1,800 cfs or less in the evenings. Flow changes of this magnitude in a short period of time can dewater areas of the river and result in a loss of macroinvertebrate diversity and habitat, as well as cause direct mortality. MDIFW believes the summer drawdowns and peaking operations were not fully anticipated in the review of the current license and therefore the water management plan may need to be refined. This study, along with the requested lake elevation and flow data, will provide information about the degree, frequency, and possible impacts resulting from the drawdowns and changes in flow. [MDIFW letter October 8, 2021, Re: MDIFW Comments and Study Requests for the Ripogenus Hydroelectric Project (FERC No. 2572) and Penobscot Mills Hydroelectric Project (FERC No. 2458), pages 35 and 36.]

Brookfield provided hourly flow data requested by MDIFW and other agency filings with the ISR Meeting Report. A preliminary analysis of August and November data performed by the National Marine Fisheries Service indicated that operations have changed and that peaking is occurring. The following example demonstrates this, many of the graphs making the comparison show 2000 flow patterns were more stable than subsequent years. This is consistent with what TU has been told through anecdotal reports.

Current studies confirm that such release practices affect both macro-invertebrate communities and fish. “The degree of hydropeaking, proximity of unregulated tributaries, and distance from the dam have been shown to have a large influence on the ultimate abundance and diversity of aquatic macroinvertebrates. [The ups and downs of hydropeaking: a Canadian perspective on the need for, and ecological costs of, peaking hydropower production, K. E. Smokorowski; Hydrobiologia (2022) 849:421–441, page 429.] “… hydropeaking operations do have negative effects on fish populations, particularly smaller bodied species or life stages, the ultimate effect on fish populations is determined by degree of hydropeaking…” [Id., page 431.] This is consistent with the results of the Stranding Study and underlines the need for a Ramping Study to determine optimal flow levels and ramping rate to achieve them to minimize or eliminate negative effects of flow changes.

TU also notes that it is well established that when flows change abruptly, fishing is disrupted for about an hour while fish readjust to the new flow. Peaking effectively takes two hours from a full fishing day, decreasing the recreational use of the resource. This is inconsistent with the world-class fishery described in the last license application for the Ripogenus Project.

# Appendix B

**Operations Model Study**

**General Comments**

For the reasons explained below, the Operations Model Study does not satisfy FERC's rationale for the study: "GLHA would use the existing operations information, along with GLHA's proposed Water Quality Study, Historical Operations Data Assessment, and Operations Model, to assess the Projects' effects on the hydrology in the West Branch and mainstem Penobscot River [section 5.9(b)(4)" [SPD, page B-42].

**Specific Comments**

1. **The use of "Daily changing target elevations" (instead of the prescribed operational targets) at Ripogenus, North Twin, and Millinocket Lake Storage in the Verification scenario needs to be clearly defined, explained, and justified.**

   The report states that "Daily changing target reservoir elevations to simulate historical operations for the Ripogenus, North Twin, and Millinocket Lake developments." for the Verification scenario (page B-27). Only in the notes for Attachment 1 does the report clarify that "for Ripogenus, North Twin, and Millinocket Lake developments, the target elevation is the historical end of day elevation reported by GLHA from the historical operations in NGVD29."

   The clarification that the "Daily changing target reservoir elevations" refers to the "historical elevations" should be mentioned and more clearly explained within the body of the report and not in an appendix note. Without further explanation, we conclude that this decision was made to make the model simulations appear more accurate than they would have been should the actual operational targets have been used.

   Furthermore, historical elevations were only used at three of the developments, while the Baseline operational targets were used at all other developments. Why use historical elevations at some but not others? This inconsistency requires explanation.

   Lastly, because **historical** elevations were used instead of **target** elevations, the results for the Verification scenario do not support the conclusion that "the Operations Model compares well to historical data, characterizes system operations, and is appropriate for use in evaluating the effects of alternative operating scenarios on generation, reservoir levels, and outflows from the System" (page B-102). **Target elevation curves are one of the most important elements of reservoir operations. Excluding these targets from the Verification Scenario means the model was not in fact evaluated for its ability to characterize system operations, but for its ability to simulate historical conditions using those historical conditions as a primary input.** In other words, by using historical elevations as an input to the model and then concluding that the simulated output elevations are reasonably accurate compared to those same historical elevations is circular logic: the same proposition occurs as both a premise and a conclusion—the argument validates itself.

2. **The report concludes the model is verified based on historical elevations, but contains insufficient comparisons of historical and simulated reservoir elevations.**

The start of Section 6.1.1 states that "The Verification scenario established in the Operations Model followed the historical operating requirements of the System by simulating daily changing target elevations to match historic elevations, historical reported spillway flows, and unit outages to simulate historical daily turbine operations" (page B-92).

However, the report does not include any quantitative evaluation of model accuracy in terms of simulating reservoir elevations. Tables 6-1 through 6-5 and Table 6-6 provide bases for evaluating model accuracy for simulating power generation and release flows, respectively. A similar comparison is not provided for reservoir elevations.

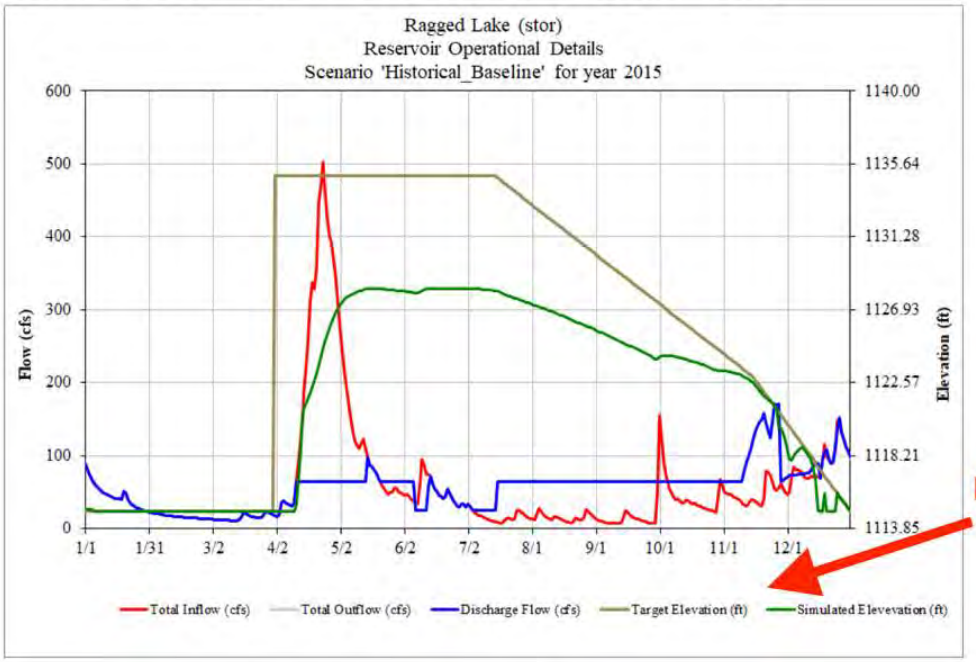
Example: Table 6-1 McKay Station [ISR page B-94]

**Table 6-1. McKay Station Verification generation comparison.**

| Year | Historical Generation (MWh) | Simulated Generation (MWh) | Difference between Historical and Simulated (MWh) | Percent Difference between Historical and Simulated (%) |
|---|---|---|---|---|
| 2015 | 211,964 | 228,520 | 16,556 | 7.81% |
| 2016 | 218,799 | 221,628 | 2,829 | 1.29% |
| 2017 | 220,978 | 221,141 | 163 | 0.07% |
| 2018 | 242,539 | 238,860 | -3,679 | -1.52% |
| 2019 | 256,618 | 240,347 | -16,271 | -6.34% |
| 2020 | 229,420 | 238,917 | 9,497 | 4.14% |
| **Average** | **230,053** | **231,569** | **1,516** | **0.66%** |

**Presumably, the conclusion that the model was verified in terms of simulating historical elevations was based on the graphical comparisons in Attachment 1. However, none of those figures includes the historical elevation for comparison against the simulated elevation.** These figures only include the target and simulated elevations. Only the figures for Ripogenus, North Twin, and Millinocket Lake developments include the historical elevation, but only because the historical elevations were used in place of the target elevations. In other words, the figures for these developments may include the historical elevations, but they are labeled as "Target Elevation," which makes it challenging for the reader to make the comparison of historical vs simulated elevations.

**Figure Attachment 1-10. Verification simulated Ragged Lake operations 2015.**



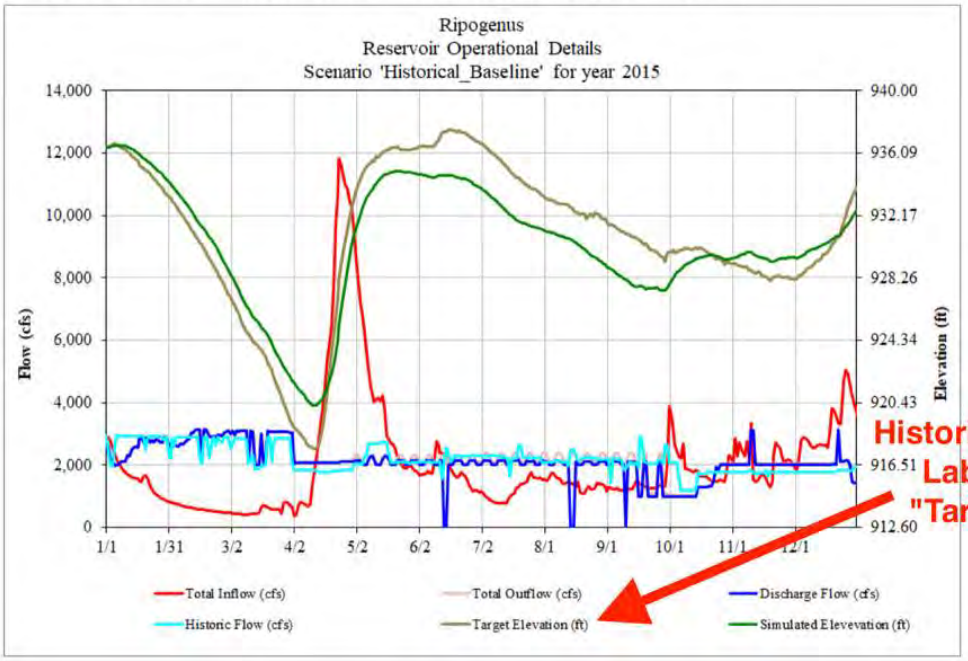


**Figure Attachment 1-11. Verification simulated Ripogenus operations 2015.**

To justify the conclusion that the model can simulate historical elevations in addition to power generation and release discharge, the report should include a quantitative comparison for reservoir elevations similar to Tables 6-1 through 6-6 and graphical comparisons that include both the historical and simulated elevations.

**3. The Operations Model Study fails to explain the derivation of the primary target elevations or why operations deviated from those targets in previous years, especially for the Ripogenus development.**

The report states that "At Ripogenus Dam, the impoundment water elevation is based on an annual rule curve that has prescribed weekly elevations that are used as a guideline to set the pond level based on the time of year. GLHA uses these elevations in conjunction with the storage available in the upstream storage ponds along with snowpack estimates in the winter months and forecasted precipitation to determine operations to maintain adherence to the rule curve" (page B-54). The target elevation curve is then provided in Table 5-5.

**Given the importance of these target elevations, a more detailed explanation for how these target elevations were identified is warranted.** For example, why lower the pool to 921.6 ft NGVD29 on April 1, why not 922 ft? What is the basis for 921.6 ft on April 1, as well as each of the other target elevations, orange highlighting supplied?

**Table 5-5. Ripogenus Development target elevation curve.**

| Date | Elevation (feet, NGVD 29) |
|---|---|
| **Target Elevations** | |
| Jan 1 | 928.6 |
| Mar 1 | 923.7 |
| Apr 1 | 921.6 |
| May 10 | 939 |
| Jul 1 | 939 |
| Oct 15 | 928.8 |
| Dec 31 | 928.6 |
| **Target Minimum Elevations** | |
| Jan 1 | 913.6 |
| Dec 31 | 913.6 |

Furthermore, the report does not discuss reasons for why the historical operations deviated from these targets. In some cases, notably in 2020 and 2021, the operational decisions that led to low reservoir levels in the Ripogenus had negative impacts on the shoreline community. Figure 1 below shows the Verification Scenario figures from Attachment 1 with the target rule curve superimposed (thick red line supplied). This figure clearly shows in what years and seasons the historical reservoir elevations deviated from the Baseline target, most notably in 2018 and 2020, areas of concern circled in orange for clarity.

Figure Attachment 1-11. Verification simulated Ripogenus operations 2015.

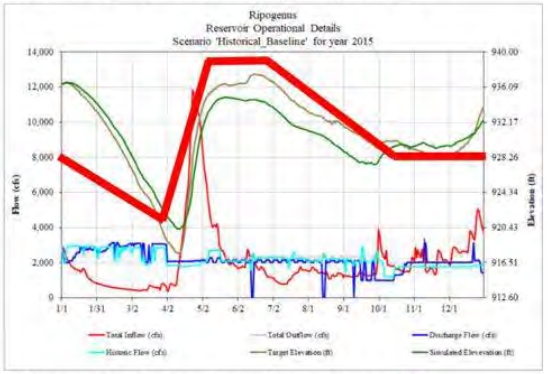

Figure Attachment 1-29. Verification simulated Ripogenus operations 2016.

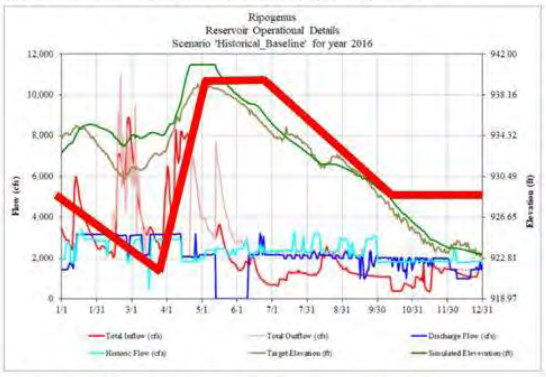

Figure Attachment 1-47. Verification simulated Ripogenus operations 2017.

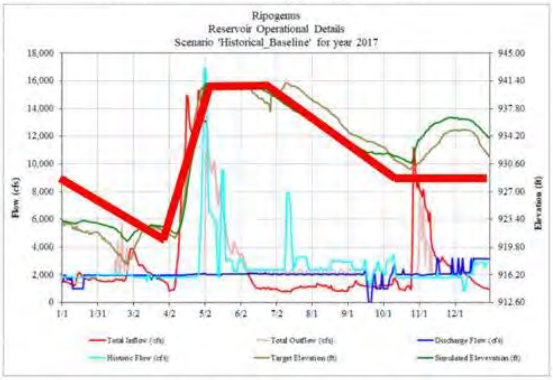

Figure Attachment 1-65. Verification simulated Ripogenus operations 2018.

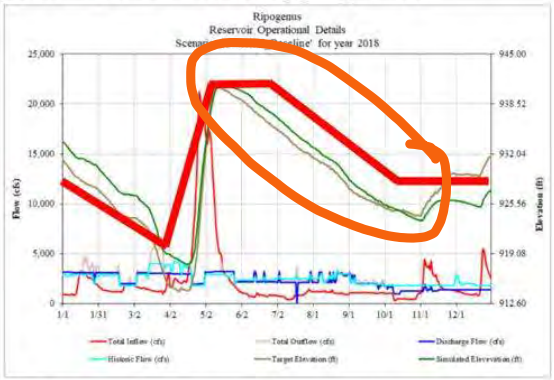

Figure Attachment 1-83. Verification simulated Ripogenus operations 2019.

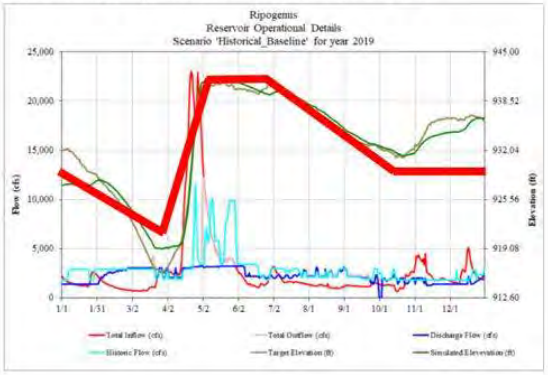

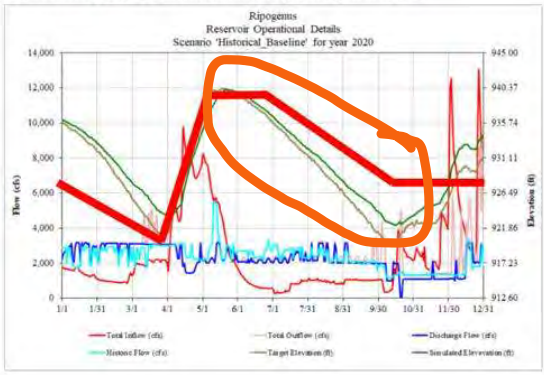

Figure Attachment 1-101. Verification simulated Ripogenus operations 2020.

**4. The Operations Model Study Report does not explain how this model will be used to develop and compare alternative operations.**

The report concludes that "the Operations Model…is appropriate for use in evaluating the effects of alternative operating scenarios on generation, reservoir levels, and outflows from the System" (page B-102).

It is not clear how those alternatives will be developed and evaluated. Given the historical negative impacts of the Ripogenus operations, especially in 2020-2021, the development and comparison of alternative operations is a critical component of the relicensing process in order to ensure the next license contains operational constraints to minimize those impacts.

**Summary of Requests**

TU requests that the Operations Model Study be resubmitted modified as described below as provided by (18 CFR 5.15(d)) paragraphs (c)(1)–(4) "(1) Approved studies were not conducted as provided for in the approved study plan;"

That the report include a clear **definition, explanation, and justification of using "Daily changing target elevations" at Ripogenus, North Twin, and Millinocket Lake Storage in the Verification Scenario**. This revision must explain how the use of historical elevations in place of target elevations at these developments supports the conclusion that the model "…compares well to historical data, characterizes system operations, and is appropriate for use in evaluating the effects of alternative operating scenarios on generation, reservoir levels, and outflows from the System" when it did not include a central component of the operational rules (namely the target elevations) in the Verification Scenario.

That the report **include quantitative (tabular) comparisons between historical and simulated reservoir elevations** for the Verification Scenario, and that **historical elevations be added and clearly labelled to the graphical comparisons in Attachment 1**.

That the report **explain: 1) the basis for the target elevations used for the Baseline Scenario (e.g., Table 5-5) and 2) reasons that historical operations led to major deviations from those target elevations** (e.g., late-summer draw down of Ripogenus in 2018 and 2020).

That Brookfield **specify the format required for requesting alternative target levels or other operational rules** to be simulated using the Operations Model. Note that such requests are NOT subject to the July 6 ISR Comment deadline.

At the ISR Meeting, "Randall Dorman (GLHA) said he anticipates that GLHA will convene a working group to develop alternative operating scenarios, and noted that alternatives should be based on study results and that stakeholders should be prepared to describe the reasoning behind any alternative request." [ISR Meeting Report, page 4]. Request that **details relating to the function of this group be published no later than with the Updated Study Report**. This would include: a plan and schedule detailing how this model will be used to evaluate alternative operating scenarios, who will participate in that process, and over what timeline.

# Appendix C

**Water Quality Study**

**General Comments**

In 2020, the Maine Legislature upgraded the West Branch from Class A to Class AA from a point 1000' below McKay station to Ambejejus Lake (MRS 38 §467.7.C(1)(d-1)). Class AA standards require that "the habitat must be free-flowing and natural" and "aquatic life …shall be as naturally occurs". While the habitat in the segment below McKay station is free-flowing, the current flow management may create 'unnatural' habitat conditions that violate the Class AA aquatic life criteria (DEP Chapter 579).

While the specific water quality studies themselves were generally favorable, details of other studies will have bearing on the FERC Environmental Analysis and Water Quality Certification. We have included them in this appendix.

The dewatered project areas Ripogenus Gorge above McKay Station (except for overflow and leakage 9 months of the year) and the Maine steam of the West Branch below Stone Dam Station (except for overflow) remain special concerns due to significant loss of habitat.

**Specific Comments**

Page C-2 The report quotes 38 MRS §464-9(A):

> "(3) The project creates an impoundment that is subject to water level fluctuations that have an effect on the habitat and aquatic life in the littoral zone so that the habitat and aquatic life differ significantly from that found in an unimpounded great pond; and
> (4) The existing impounded waters are able to support all species of fish indigenous to those waters and the structure and function of the resident biological community in the impounded waters is maintained."

The applicant then does not apply this standard fully, notably subparagraph (4) to the Results section that follows in the Water Quality Study Report. See Page C-103 and C-107 comments below.

Page C-81 Macroinvertebrate studies below Stone Dam did not meet Maine Water Quality Criteria. "The rock basket samplers installed downstream of Stone Dam for a 29-day period beginning on July 20, 2022, did not meet MDEP criteria specifying that an average of 50 specimens across the three replicates be collected to evaluate attainment." DEP Chapter 579. 3.G.(2)(a) states that a determination of nonattainment can be made when there are no confounding sampling factors (as indicated in paragraph 3.G.(1)) which could be applied in this case (i.e., the low count of organisms is not due to a sampling error but due to the stressed habitat). Note that the West Branch segment below Stone Dam is presently listed in the Maine DEP's 305(b) list of nonattaining waters (category 4C).

Page C-103 Table 5.2-14 Although historically present, 2022 sampling did not confirm the presence of lake trout, lake whitefish, or American eel.

**Page C-107 Tables 5.2-17 through 20 while showing diversity, do not confirm that the project is supporting the structure and function of the resident biological community. There is no data in the report about macroinvertebrate species presence or absence**, example: mussel species in the littoral zone. While the composition may differ, the structure and function of the resident biological community in the impounded waters must be maintained. It is difficult to see how this would have been achieved given the severe drawdowns of the impoundment that occurred during 2020 and 2021. Following MDEP guidance, three-quarters of the littoral zone should be kept watered to maintain the "structure and function of the resident biological community in the impounded waters" of this critical lake habitat zone. That did not occur for significant portions of those years.

The effects of drawdowns on nesting loons in the impoundment were significant: nesting platforms not used from 2002 to 2010 at most sites. No data from 2010 on. Brookfield says observations were made but not recorded. Lake levels needed for successful loon nesting has not occurred 3 out of the last 11 years. [ISR, Appendix L]

In the absence of additional information, Maine Water Quality Certification criteria necessary to protect designated uses have not been shown to have been met and a Use Attainability Analysis (UAA; 38MRS §464.2-A) should be conducted before modifying any of the designated uses of these waters to allow the project to gain Clean Water Act Certification.

Page C-111 Ripogenus Gorge. Managed for salmonids, temperatures exceeded 23 degrees Celsius in early August.

Page C-134 Macro-invertebrate Study below McKay Tailrace: "Due to the relative abundance of Hydropsyche at this site, the Shannon Diversity index score of 1.53 trends towards an imbalance in the distribution of individuals among all taxa present." This may present a problem regarding the upgraded Water Quality Classification.

Page C-173 Below Millinocket Lake Dam. Temperatures exceeded 27 degrees in mid-August.

Page C-182 Below Stone Dam. Temperature exceeded 25 degrees Celsius in both July and August.

The Fish Assemblage Study uses data collected in 2003 [Fish Assemblage Study Report, page D-4 and D-8] that is over 20 years old. American Rivers v. Federal Energy Regulatory Commission (American Rivers III), ELR Citation: 48 ELR 20113, No(s). 16-1195 (D.C. Cir. Jul 6, 2018), page 29 established a decade as a reasonable study period of usefulness. **Fresh data is needed to confirm the presence of native fish as required by MDEP.**

It is also significant that the habitat created by releasing water through the sluiceway from July 1 to September 30 uses the warmest water in the Ripogenus - Chesuncook Impoundment. This appears to be attracting fall fish rather than the landlocked salmon and brook trout that it was designed to provide a fishery for [Fish Assemblage Study Report, page D-71], orange highlighting provided for clarity.

**Table 29 Fish collected in the Upper Gorge (All Methods)**

| Species | No. Captured | Percent of Total |
|---|---|---|
| Fallfish | 24 | 34.3% |
| Blacknose Dace | 15 | 21.4% |
| White Sucker | 12 | 17.1% |
| Landlocked Salmon | 11 | 15.7% |

North Twin Littoral Zone North Twin, dewatered area exposed more than 75 per cent of the littoral zone [Riparian-Littoral Study, page K-16

> "The minimum elevation of the impoundment during the low water year (2021) was 482.80 feet, which is approximately 9.12 feet below the normal full pond elevation of the impoundment. At this elevation, approximately 4,921 acres were exposed, which is approximately 26 percent of the total surface area of the impoundment. This is similar to the amount of exposed area under the 11-year average annual minimum elevation at the Project (482.26 feet), which resulted in approximately 5,081 acres of exposed area and equates to approximately 27 percent of the total surface area of the impoundment."

# Appendix D

**Fish Assemblage Study**

**Comments**

No Lake whitefish were collected during this round of data collection

Pages D-4 and D-8 The Fish Assemblage Study uses data collected in 2003 that is over 20 years old. American Rivers v. Federal Energy Regulatory Commission (American Rivers III), ELR Citation: 48 ELR 20113, No(s). 16-1195 (D.C. Cir. Jul 6, 2018), page 29 established a decade as a reasonable study period of usefulness. Fresh data is needed to confirm the presence of native fish as required by MDEP.

Page D-71 It is also significant that the habitat created by releasing water through the sluiceway from July 1 to September 30 uses the warmest water in the Ripogenus - Chesuncook Impoundment. This appear to be attracting fall fish rather than the landlocked salmon and brook trout that it was designed to provide a fishery for - orange highlighting provided for clarity.

**Table 29 Fish collected in the Upper Gorge (All Methods)**

| Species | No. Captured | Percent of Total |
|---|---|---|
| Fallfish | 24 | 34.3% |
| Blacknose Dace | 15 | 21.4% |
| White Sucker | 12 | 17.1% |
| Landlocked Salmon | 11 | 15.7% |
| Slimy Sculpin | 4 | 5.7% |
| Creek Chub | 2 | 2.9% |
| Brook Trout | 1 | 1.4% |
| Yellow Perch | 1 | 1.4% |
| **Total** | **70** | **100.0%** |

D-107 Lake trout, lake whitefish and American eel were not sampled in 2022.

Scale samples and fish metrics were not taken.

# Appendix E

**Fish Stranding Study**

**General Comments**

**The study results contained in the ISR showed significant mortality, especially to landlocked salmon parr. These results were quite similar to the observations of the five teams of TU observers who were in the field during the drawdown.** Strandings and mortality were likely undercounted by the report because a high stranding area in the center of Big A Falls documented by TU volunteers was not covered by Brookfield. ISR Figure 7, page E-33]. The study demonstrates that the minimum flows for trip events were not determined by science.

Moreira et. al. 2019 worked to develop an ecologically based criteria for hydropeaking mitigation. They conclude "Hydropeaking causes severe changes in riverine environments, entailing adverse responses of organisms" (Miguel Moreira, Daniel S. Hayes, Isabel Boavida, Martin Schletterer, Stefan Schmutz, António Pinheiro, 2018, Ecologically-based criteria for hydropeaking mitigation: A review, *Science of the Total Environment*). This underlines the need for a ramping study to determine a ramping rate that minimizes stranding for fish in the river. When it filed its report to the FERC docket, [TU letter dated October 19, 2022, Subject: Report of Observations on Ripogenus Project Fish Stranding Study] TU included this request: "The Initial Study Report from Brookfield is not due until May 13, 2023.[1] We trust that it will be consistent with our observations, and if it does not include empirical data indicating flows and duration of dewatering required to prevent future mass strandings, that Brookfield will propose additional studies to determine that." Since Brookfield has not proposed a follow-on study. **TU urges the Commission to approve a Ramping Study to determine the flow parameters that will greatly reduce or eliminate strandings and resultant mortality**.

**Specific Comments**

Brookfield states that "The early October time frame was selected for the study because it represented a biologically active period for salmonids and other species but was outside the fishing and peak whitewater rafting seasons, thus minimizing conflict with recreational activities. The early October date was also before the onset of the salmonid spawning season, so it did not adversely affect spawning landlocked salmon." Please note that this was **during a very benign period of weather conditions minimizing stranding mortality**. While little macroinvertebrate mortality was observed, it would have been increased if the low flows happened during the hot summer thunderstorm conditions and the cold winter conditions that come with Northeast storms that often cause trip events.

Brookfield states: "During the October 5, 2022 simulation, TU organized and conducted a separate fish stranding monitoring effort using several volunteers to monitor the West Branch." Please note that five two-person teams participated in the coordinated monitoring effort.

Page E-2 "In February 2018, GLHA implemented the procedure for minimum flows during unplanned outages. The change in operations was implemented after GLHA determined that operational procedures relying on spinning the turbines instead of braking was more effective and provided outage flows of at least 400 cfs." This is deceptive - the 400 cfs minimum during generator trip events has been in place since 2017. Brookfield developed an improved method of implementing McKay Stations

response to a trip event after experiencing the outage that occurred on August 13, 2015 when system failure resulted in outage flows of only 342 cfs versus the required 400 cfs. [Brookfield letter dated August 24, 2015, RE Ripogenus Project 2572; Article 402 Compliance; Penobscot Mills Project; Article 403 Compliance; Flow Excursions due to Transmission Line Trip and Station Outages]

Page E-5 "Weather conditions during the stranding study were clear and cool, with an air temperature of approximately 35 degrees Fahrenheit (°F) at the start of the day, warming to approximately 60 °F at the study termination." Please note these are relatively benign conditions that worked to minimize mortality for fish and especially macro-invertebrates.

Page E-7 Table 2 please note prior comments. The conditions on March 14, 2018 and August 30, 2021 would not likely have been so conducive to the survival of stranded fish and macro-invertebrates, orange highlighting supplied.

**Table 2. Summary of Unplanned Station Outages at McKay Station from 2018 to 2022**

| Date | Start Time | End Time/ Flow Restored | Root Cause | Duration (hours) |
|---|---|---|---|---|
| 3/14/2018 | 2:43 AM | 6:13 AM | Wind Storm | 3.5 |
| 7/18/2018 | 10:49 AM | 12:10 PM | Broken Cross Arm | 1.4 |
| 9/30/2020 | 11:05 AM | 4:27 PM | Wind Storm | 5.4 |
| 8/30/2021 | 12:04 PM | 3:15 PM | Lightning Strike | 3.2 |
| 9/16/2021 | 7:32 AM | 10:00 AM | Versant Line 62 outage | 2.5 |
| **Average Duration of Station Trips** | | | | **3.2** |

Page E-8 Table 3 is deceptive. The photos provided with the TU report show the large areas the change in flows created. We also question the actual water level drops. TU observers saw that new areas were still being exposed over two hours after the flow was reduced in the Cribworks area below Telos Bridge highlighted in orange below. TU challenges that "much of the main river channel remained inundated at the low flow condition." This is reflected both later in the Brookfield report and in the TU report by the large number of strandings and significant mortality, even under relatively benign weather conditions. Brookfield provided photos selectively: areas poorly channelized or large deep pools.

**Table 3. Changes in Water Surface Elevation Observed during the Stranding Study***

| Site / Stream Reach | Elevation (ft) on Staff Gage at Start (2,200 cfs) | Elevation (ft) on Staff Gage at Low Flow (510 cfs) | Change in Elevation (ft) |
|---|---|---|---|
| Holbrook Side Channel | 16.4 | 16.4 | 0.0 |
| West Branch at Telos Bridge | 24.8 | 21.4 | 3.4 |
| West Branch at Big Eddy | 23.8 | 21.7 | 2.1 |
| West Branch at Little A | 23.6 | 21.8 | 1.8 |
| West Branch at Nesowadnehunk Deadwater | 2.8 | 1.4 | 1.4 |

*Measurements were of relative water surface elevation at each location; measurements at each location were not related to one another or to any known point of elevation.

TU photo from near the Holbrook side channel

TU photo from the Cribworks area, where only about one third of the bankfull wetted area remained watered. **The rocks shown are watered under nominal 2000 cfs flows, the drop in elevation is clearly more than the 3.4 feet reported in Table 3.**

Major dewatering also occurred at Little A Falls

And at Big A Falls

Page E-9 The ISR goes on to say that “Areas of boulder and cobble bars, bedrock ledges, and fine substrates (e.g., sand and silts) were exposed at the low flow (510 cfs) condition throughout the study reaches; however, much of the main river channel remained inundated at the low flow condition.” This is immaterial given the large dewatered areas and observed strandings and mortality. Brookfield’s own photos document extensive dewatering: Photo 9 [ISR page E-15], Photo 10 and Photo 11 [ISR page E-16], Photo 13 and Photo 14 [ISR, page E-19], Photo 19 and Photo 20 [ISR page E-24], Photo 28 [ISR, page 32], Photo 30 [ISR, page E-35], and Photo 32 [ISR, page E-36].

Page E-33 **Area not covered at Big A Falls** (orange highlighting supplied) noted as high stranding area in TU report [TU letter dated October 19, 2022, Subject: Report of Observations on Ripogenus Project Fish Stranding Study, Attachment M, page 31.] **likely resulted in undercounting.**

**Figure 7. Summary of Observed Fish and Macroinvertebrate Strandings – Big A Falls Reach, October 5, 2022**

E-38 Brookfield summarized that “Stranded fish were observed throughout seven distinct reaches of the West Branch between McKay Station and the Nesowadnehunk Deadwater. Approximately 450 stranded fish were observed during the study, representing nine species: landlocked salmon, brook trout, slimy sculpin, blacknose dace, common shiner, white sucker, fallfish, yellow perch, and banded killifish. Most stranded fish were young-of-year landlocked salmon (55 percent) followed by blacknose dace (31%) and banded killifish (5%) (Table 4). Of the stranded fish observed, approximately half were classified as mortalities. Most stranded fish were small bodied species and lifestages such as juvenile landlocked salmon, dace, and sculpin. No observations of large adult landlocked salmon or adult brook trout occurred.”

TU documented one adult landlocked salmon at Big A Falls and another large fish also being consumed by a merganser in the Holbrook area. It can be reasonably assumed that there were others.

**Ramping Study**

A Ramping Study would inform the project participants by determining minimum flow changes protective of fish and aquatic communities. The Licensee presently ramps flows below the Caucomgomoc and Brassua Lake Dams. Ramping is commonly requirement in FERC Licensed projects.

**Additional Study Request**

In accordance with 18 CFR 5.15(e), the following is submitted to justify the request.

(1) *Any material changes in the law or regulations applicable to the information request*: there have been no material changes in the law or regulations applicable to this request.

(2) *Why the goals and objectives of any approved study could not be met with the approved study methodology*: No approved study addressed the minimum flows that would preclude or minimize strandings or the rates of achieving those flows that preclude or minimize mortality. TU supported a Ramping Study in its Proposed Study Plan Comments. Information on adequate flows or alternative means of project operations such as ramping to prevent this mortality was not contained in any of the studies included in the ISR.

(3) *Why the request was not made earlier.* Such a study was proposed as a Pre-application Document Comment [Ed Spear letter dated February 12, 2022, Subject: A study Request; Ramping and the Need to Determine the Appropriate Rate of Flow Change Below McKay Station on the West Branch of the Penobscot River] but was not included in the studies FERC approved in its Study Plan Determination (SPD)[ FERC Study Plan Determination for the Ripogenus Hydroelectric Project and the Penobscot Mills Hydroelectric Project dated May 13, 2022, page A-1].

(4) *Significant changes in the project proposal or that significant new information material to the study objectives has become available:*.. The Licensee stated there have been no change in Project operations. This is incorrect. Project operations have changed from relatively base flow for papermaking to a market driven peaking regime. Stranding Study decisively demonstrated that permitted project operations allow abrupt changes in flow that result in significant strandings of fish and macroinvertebrates with significant mortality noted, especially to landlocked salmon parr. This conclusively demonstrated the need for a Ramping Study to determine environmentally safe flows changes and the ramping rates needed to achieve them.

(5) *Why the new study request satisfies the study criteria in § 5.9(b):* The following resubmits the ramping study request in accordance with § 5.9(b).

*1. Describe the goals and objectives of each study proposal and the information to be obtained.*

The goal of the study is to determine safe ramping rates as well as minimum safe flows and the ramping rates needed to achieve them.

2*. If applicable, explain the relevant resource management goals of the agencies or Indian tribes with jurisdiction over the resource to be studied.*

Ramping rate studies are a recognized way to determine ramping rates that reduce or eliminate resultant mortality. Brookfield is well aware of such studies from a multi-year study on ramping effects for the Magpie River Project in Wawa, Ontario since the project is operated by a Brookfield subsidiary. The study is described by Karen E. Smokorowski, Robert A. Metcalfe, Nicholas E. Jones, Jerome Marty, Shilei Niu, and Richard S. Pyrce. Studying Ramp Rate Restrictions, Hydro Review, July 2009.

*3. If the requester is not a resource agency, explain any relevant public interest considerations in regard to the proposed study*.

TU members fish the West Branch of the Penobscot regularly. For many of our members, this is one of our most favored fishing destinations, one that we endeavor to revisit every year. TU has a strong and continuing interest in the terms of the relicensing of the West Branch projects. TU's fisheries interests parallel the general public interest.

4*. Describe existing information concerning the subject of the study proposal, and the need for additional information*.

The Stranding Study demonstrated that an abrupt change from flows of about 2000 cfs to trip event flows of 500 cfs caused significant strandings and mortality, primarily to landlocked salmon parr. The Stranding Study identified areas where dewatering, stranding and mortality occurred. This information can be used to position observers for the ramping study. As stated in the SPD: "As discussed in our recommendations regarding Study 5, the Fish Stranding Study, rapid changes in flow and decreases in water surface elevations can increase the risk of fish and invertebrate stranding that can be stressful and/or lethal for aquatic organisms. As indicated by GLHA, the proposed Historical Operations Data Assessment, would provide information on how the Ripogenus Project is operated, including flows provided by McKay Station. However, it is unclear how this study would determine whether the current rate of downstream flow changes adversely affects aquatic resources or how it would determine the rate at which flows from McKay Station can be ramped up or down to minimize the effects of project operations on aquatic resources." There is no empirical data in the record that documents safe flow change for the Ripogenus Project or the ramping rates needed to achieve them.

*5. Explain any nexus between project operations and effects (direct, indirect, and/or cumulative) on the resource to be studied, and how the study results would inform the development of license requirements*.

Changes in the manner in which flow changes are implemented and the limits on them are needed to improve protection of fish and aquatic communities. Results of the study would directly inform development of terms and conditions of a new license to prevent flow changes at rates that would cause dewatering, stranding and mortality.

6. *Explain how any proposed study methodology (including any preferred data collection and analysis techniques, or objectively quantified information, and a schedule including appropriate filed season(s) and the duration) is consistent with generally accepted practice in the scientific community or, as appropriate, considers relevant tribal values and knowledge.*

Methodology for ramping studies is well documented in Magpie River Ramping Rate Study, Experiment Design, Fisheries and Oceans Canada (DFO), Great Lakes Laboratory for Fisheries and Aquatic Sciences, Sault Ste. Marie. Ontario Ministry of Natural Resources (OMNR)
Great Lakes Power Ltd. (GLPL) July 11, 2002.

The study should be conducted in early October before the effective date of spawning flow restrictions: October 15.

Nominal whitewater flows of 2000 to 2400 cfs should be in effect for a week prior to the study event(s).

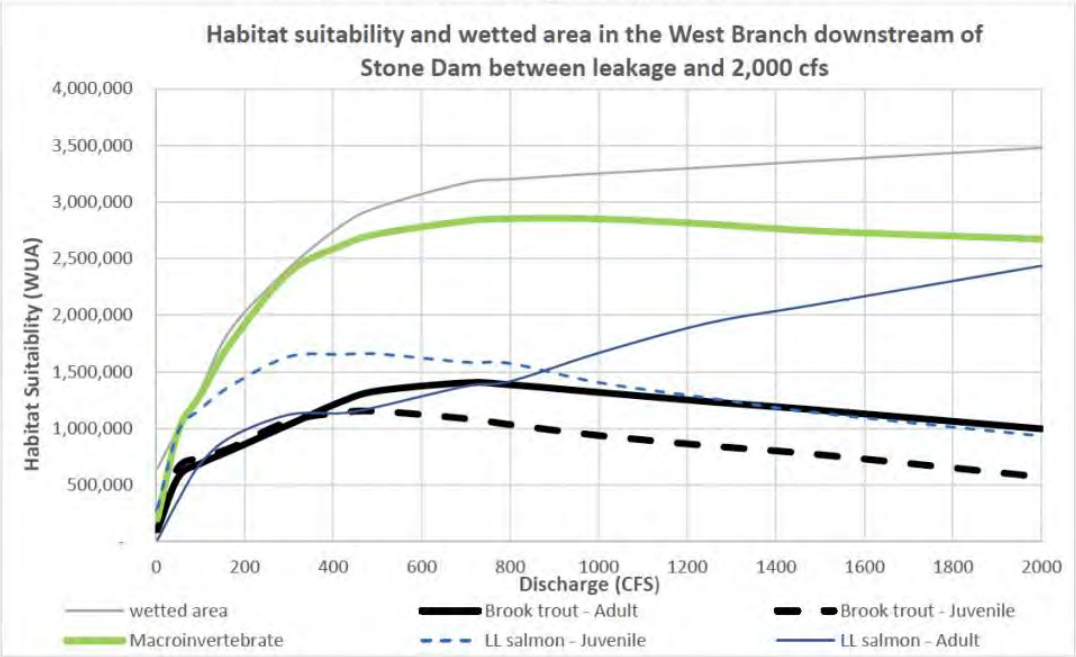
Suggested range of flows: 3600 cfs (hydraulic limit) to 500 cfs (trip event flow).

If strandings occurs at the initial rate chosen for the study, result in strandings, the ramping would be repeated on subsequent days at lesser ramping rates until a safe ramping rate was found.

The proposed study methodology is consistent with current practice and consistent with the values of the Penobscot Indian Nation.

7. *Describe considerations of level of effort and cost, as applicable, and why proposed alternative studies would not be sufficient to meet the stated information needs*.

Estimated cost is $25,000, consistent with a project of this size and importance. The stranding Study conducted by Brookfield did not meet information ramping goals and are inadequate to inform improved terms and conditions.



# Appendix F

**Comments**

**Instream Flow and Habitat Assessment of West Branch Downstream of Stone Dam Study**

Page F-11 Figure 2 below shows best suitability for adult brook trout and landlocked salmon between 700 cfs and 1000 cfs. Wetted area curve begins to flatten out at those flows. This is an excellent range for macro-invertebrate life.

**Figure 2. Habitat suitability and wetted area in the West Branch downstream of Stone Dam between leakage and 2,000 cfs.**

Consulting StreamStats, the drainage area above Stone Dam is 1894 sq/mi and the mean August baseflow cfs/mi2 is .46. This results in a minimum flow of 871 cfs, slightly above the middle of the range.

The Water Quality Study showed that the area below Stone Dam did not meet standards for macro-invertebrates: “The rock basket samplers installed downstream of Stone Dam for a 29-day period beginning on July 20, 2022, did not meet MDEP criteria specifying that an average of 50 specimens across the three replicates be collected to evaluate attainment.” [ISR, page C-81]

The Water Quality Study also showed high water temperatures (exceeding 27 degrees Celsius) below Stone Dam for the period of July 28 to August 8 occurring below Stone Dam. [ISR, page C-187]

700 cfs to 1000 cfs would also provide cooler, better oxygenated water, allow for whitewater use, and improved aesthetics. For the Turners Falls Project, (P-1889) on the Connecticut River, FirstLight conducted a 'persistent' habitat analysis that examined habitat that persists throughout a range of operational flows (Accession Number 20170501-5352). It seems reasonable that Brookfield should be able to do a similar study.

**TU strongly supports a wadability study to determine how best to optimize the area for wade fishing, and additional whitewater studies to determine the best whitewater flows.**

# Appendix G

**North Twin Impoundment Tributary Access Survey Study**

**Comments**

Page G-17 “The combination of atypical, high impoundment levels and high stream discharges created circumstances that prevented potential instream barriers from being adequately detected or surveyed. The protracted period of unseasonably warm weather also delayed and/or altered spawning behavior of salmon to the extent that it was not feasible to document evidence of spawning (Kevin Dunham, MDIFW, personal communication). Therefore, GLHA anticipates completing this survey during the 2023 field season.”

It was noted during the ISR Meeting that **the report omitted survey data collected in the impoundment itself in the vicinity of the tributaries. TU strongly requests that this data be included with the Updated Study Report.**

**TU strongly recommends that this year’s study includes the use of radio tags.** Recent spawning studies conducted incident to the ongoing Aziscohos Project (P-4026) relicensing demonstrated the importance of radio-tracking in these studies when year-one studies could not determine where spawning was occurring. Radio-tracking is technology is best science available, the standard for FERC directed studies.

# Appendix H

**Upstream Eel Passage Assessment Study**

**Comments**

Page H-15 It was significant that "between June 7 and October 17, 2022, biologists observed a total of approximately 556 juvenile eels at the East Millinocket Dam during the monitoring period."

Page H-19 It was significant that American eels were by far the most numerous species captured by electrofishing downstream of East Millinocket Stream. See table 3 below, orange highlighting supplied.

**Table 3. Fish Species Documented Downstream of the East Millinocket Development during Boat Electrofishing Surveys, June – October 2022**

| Species | Jun 29 | Jul 20 | Aug 24 | Sep 21 | Oct 10 | Total Catch per Species | Percent of Catch per Species |
|---|---|---|---|---|---|---|---|
| American eel | 93 | 53 | 3 | 2 | 2 | 153 | 44.7% |
| Smallmouth bass | 21 | 23 | 10 | 11 | 30 | 95 | 27.8% |
| Redbreast sunfish | 8 | 8 | 5 | 10 | 16 | 47 | 13.7% |
| White perch | 1 | 8 | 4 | 3 | 0 | 16 | 4.7% |
| Fallfish | 0 | 8 | 1 | 2 | 0 | 11 | 3.2% |
| Pumpkinseed | 0 | 0 | 2 | 0 | 9 | 11 | 3.2% |
| Yellow perch | 4 | 0 | 1 | 1 | 2 | 8 | 2.3% |
| Landlocked salmon | 1 | 0 | 0 | 0 | 0 | 1 | 0.3% |
| **Monthly Total** | **128** | **100** | **26** | **29** | **59** | **342** | **100.0%** |

H-19 "No eels were collected during 1 month of trapping; therefore, trapping was discontinued on July 28.

**TU understands that Brookfield will conduct nighttime eel studies upstream at the dams in the Penobscot Mills projects this summer - TU supports this.**

# Appendix I

**Desktop Downstream Eel Passage Route and Survival Study**

**Comments**

**Table 37. Estimates of American eel cumulative passage success from potential outmigration locations within the Ripogenus and Penobscot Mills Project areas under a 50% outflow exceedance condition**

| Potential Outmigration Source | Project-Development Survival | | | | | Cumulative Survival |
|---|---|---|---|---|---|---|
| | Ripogenus | North Twin | Millinocket | Dolby | East Millinocket | |
| Ripogenus Impoundment | 62.9% | 53.6% | 62.1% | 49.0% | 62.1% | 6.4% |
| Upper Gorge, West Branch downstream of McKay Station, Ambajejus Lake, Pemadumcook Lake, North Twin Lake, South Twin Lake | - | 53.6% | 62.1% | 49.0% | 62.1% | 10.1% |
| Quakish Lake, Ferguson Pond | - | - | 62.1% | 49.0% | 62.1% | 18.9% |
| Millinocket Lake, West Branch downstream of Stone Dam, Shad Pond, Dolby Pond | - | - | - | 49.0% | 62.1% | 30.4% |
| West Branch between Dolby dam and East Millinocket dam | - | - | - | - | 62.1% | 62.1% |

Page I-71 **Table 37 shows 6% cumulative survival for eels starting downstream above Ripogenus Dam (highlighted). This is abysmal.**

TU looks forward to a MDMR filing that will suggest changes to trash rack spacing and other measures.

It should be noted that past fish assemblage reports have shown the presence of adult eels in the system. This photo documents one. [Midwest Biodiversity Institute Development of Methods and Designs for the Assessment of the Fish Assemblages of Non-Wadeable Rivers in New England dated December 31, 2015, page A-7}

# Appendix J

**Terrestrial, Wildlife, and Botanical Resources Study**

TU has no comment.

# Appendix K

**Riparian and Littoral Habitat Assessment Study**

**Comments**

Page K-16 North Twin, dewatered area exposed more than 75 per cent of the littoral zone:

> "The minimum elevation of the impoundment during the low water year (2021) was 482.80 feet, which is approximately 9.12 feet below the normal full pond elevation of the impoundment. At this elevation, approximately 4,921 acres were exposed, which is approximately 26 percent of the total surface area of the impoundment. This is similar to the amount of exposed area under the 11-year average annual minimum elevation at the Project (482.26 feet), which resulted in approximately 5,081 acres of exposed area and equates to approximately 27 percent of the total surface area of the impoundment."

# Appendix L

**Loon Management Plan Assessment Study**

**Comments**

The effects on nesting loons in the impoundment were significant: nesting platforms not used from 2002 to 2010 at most sites. No data from 2010 on. Brookfield says observations were made but not recorded.

No active management program evident.

Lake levels needed for successful loon nesting has not occurred 3 out of the last 11 years.

# Appendix M

**Marsh Bird Survey Study**

TU has no comment.

# Appendix N

**Furbearer Survey Study**

Study is on-going; report to be provided in the Updated Study Report. Accordingly, TU has no comments.

# Appendix O

**Wood Turtle Habitat and Presence Study**

TU has no comment.

# Appendix P

### Recreation Study

### General Comments

A relatively low number of survey forms were completed. FERC recommended use of interviewers.

Further recreational studies must include interviewers in the field. See page P-118 and subsequent.

The recreation season extends through September and studies should reflect this.

### Specific Comments

Page P-126 Survey counts:

**Table 5.14 Counts of Recreation Activities at the McKay Station Rafting Put-in.**

| Activity | Spring (Apr-May) | Summer (Jun-Aug) | Fall (Sep-Nov) | Winter (Dec-Mar) | Total |
|---|---|---|---|---|---|
| Birding | 0 | 2 | 0 | 0 | 2 |
| Power Boat* | 0 | 0 | 1 | 0 | 1 |
| Jet Ski* | 0 | 1 | 0 | 0 | 1 |
| Camp* | 1 | 6 | 3 | 0 | 10 |
| Canoe/Kayak | 7 | 13 | 7 | 3 | 30 |
| Drive for Pleasure | 4 | 8 | 5 | 3 | 20 |
| Educational Program | 1 | 1 | 1 | 0 | 3 |
| Fish from Boat | 2 | 6 | 5 | 0 | 13 |
| Fish from Shore | 4 | 14 | 8 | 0 | 26 |
| Hike | 6 | 12 | 9 | 5 | 32 |
| Cross Country Ski | 0 | 0 | 0 | 2 | 2 |
| Snowshoe | 0 | 0 | 0 | 1 | 1 |
| Nature Observation | 2 | 7 | 4 | 2 | 15 |
| Paddleboard | 2 | 4 | 2 | 1 | 9 |
| Photography | 3 | 7 | 5 | 2 | 17 |
| Picnic | 2 | 6 | 6 | 0 | 14 |
| Scenic Viewing | 6 | 10 | 8 | 3 | 27 |
| Sightsee | 3 | 6 | 6 | 1 | 16 |
| Sunbath | 1 | 4 | 3 | 0 | 8 |
| Swim | 1 | 7 | 5 | 0 | 13 |
| Walk | 1 | 6 | 4 | 0 | 11 |
| Whitewater Boating** | 12 | 17 | 13 | 4 | 46 |

*This is how the information was provided on the survey form, but there are no powerboating, jet-skiing, or camping opportunities at McKay Station. Swimming is not authorized near McKay Station. Paddleboarding opportunities are limited to the same whitewater reach used by whitewater boaters.
** Note, the survey did not distinguish between rafting and other types of whitewater boating (kayak, canoe, etc.).

Highlighted fishing survey numbers are inadequate to assess use. Numbers describing use of the Gorge Trail are deceptive. “Uriah Forest-Bulley (KA) said the users at the Upper Gorge Trail included people who drove to that parking area, enjoyed the views from the dam, and then left, so some users only used the parking area but not the trail.” [ISR Meeting Report, page 15]. Other survey counts were inadequate as well.

Page P-51 and subsequent. The number of fisheries surveys received was insufficient, especially when compared to creel surveys accomplished for the last relicensings. [Ripogenus Project Application for New License dated December 1991, Volume X, Appendix C].

Page P-152 and P-153 Fisheries data was inadequate, example for page 152: Although the area below McKay Station to Nesowadnehunk is fished heavily, a total of only 14 fish were included.

**Table 5.44 Species of fish caught and size information from respondents at the Ripogenus Project recreation sites.**

| Species of Fish Caught | Fish Size Information | Count |
|---|---|---|
| *Upper Gorge Trail* | | |
| Landlocked Salmon | All fish were released | 1 |
| | | |
| *McKay Station Rafting Put-in* | | |
| Salmon, brook trout, yellow perch, fallfish | None kept. 6-9" brook trout. 8-18" salmon | 1 |
| N/A/none | None | 2 |
| Landlocked salmon, brook trout, chub | None kept, 15” | 1 |
| Landlocked Salmon | None kept, 25 between 8” and 18” | 1 |
| Landlocked Salmon | None kept, about 11 inches | 1 |
| Brook trout, landlocked salmon | None kept | 3 |
| Brook trout, landlocked salmon | All fish were released | 1 |
| Brook trout, landlocked salmon | 15 inches, 1lb | 1 |
| Brook trout, landlocked salmon | None kept, 8 to 18 inches | 1 |
| Trout | None kept, 5 10-18" | 1 |
| | | |

**Repeating a passive survey will likely result in the same outcomes. TU request that a new Creel Survey with active interviewers in the field to collect data comparable to that submitted with the last relicensing. An additional study request is included at the end of this appendix.**

Area below Stone Dam - watering below dam and access are issues. To access the river below Stone Dam during overflow conditions, paddlers must row about a mile to get to the dam. There is a road that extends nearly to the dam, but a locked gate precludes access.

**TU supports the contention that boating flow studies are needed below Stone Dam and suggests that they be combined with wadability studies.**

**TU Supports Boat Access Studies at Stone Dam - Chesuncook and Ripogenus Gorge as** well.

Millinocket Stream has recreational interest and additional whitewater potential.

**Additional Study Request: Creel Survey**

The Study Plan Determination stated:

"In order to partially address the request from Edward Spear to conduct a Creel Survey (see Part II – Studies Not Required) and his comments on the RSP, the Recreation Study could also be modified to collect some basic information about the recreational fishery through additional questions on the recreation user surveys. Because adding questions to the recreation survey would require less effort than conducting a separate creel survey [section 5.9(b)(7)], we recommend modifying the survey instrument to include a section of angler-specific questions (e.g., if the user is there to fish, what species are they targeting, how long did they spend fishing/length of trip, what species did they catch, how many fish were kept, approximate size, etc.)." [SPD, page B-41]

The ISR included a very limited amount of fisheries data in the Recreation Study Report and this was not supported by any interviews as FERC Staff had requested. "Dustin Wilson (FERC) said stakeholders recommended qualitative interviews, and FERC's SPD recommended interviews with users or working groups; however, FERC did not see this reflected in the study report." [ISR Meeting Summary, page 17] More information is required and the lack of success using passive survey methods is a clear indication that putting surveyors in the field is necessary to be able to make any reasonable assessment of the state of the fishery. Creel surveys were conducted incident to the last relicensing and the proposed survey would provide better data for comparison.

A Creel Survey was requested by Mr. Ed Spear incident to the Pre-application Document Comments in his letter dated February 12, 2022 but was not included in the studies FERC approved in its Study Plan Determination (SPD). The following request borrows from the previous filing.

In accordance with 18 CFR 5.15(e), the following is submitted to justify the request.

(1) *Any material changes in the law or regulations applicable to the information request:*
there have been no material changes in the law or regulations applicable to this request.

(2) *Why the goals and objectives of any approved study could not be met with the approved study methodology:* Anglers did not respond to the passive survey and the applicant did not use interviewers in the field as FERC had requested.

(3) *Why the request was not made earlier*. The request for a creel survey was made as a Pre-application Document comment request by Mr. Spear but not included as an approved study in the Study Plan Determination.

(4) *Significant changes in the project proposal or that significant new information material to the study objectives has become available*: The dearth of information contained in the Recreation Report requires a different approach. Peaking operations occurring below Ripogenus that TU cited in Appendix A of this filing demonstrate that a change in project operations has occurred making determination of its effects

important to this relicensing. As TU states in Appendix C of this filing, the Fish Assemblage Study used some data over 20 years old. Considered as a whole, the state of the fishery remains under-informed; compared to the fisheries information contained in the last license application, the current relicensing is woefully uninformed after the completion of year-one studies.

(5) *Why the new study request satisfies the study criteria in § 5.9(b):* The Creel Survey Study Request that follows meets § 5.9(b) requirements.

**Creel Survey Study Request**

Study Request: A creel survey to determine daily and annual West Branch of the Penobscot River angler use, effort, catch, method (drift boat, watercraft, wading, etc.) and (riverine) location of anglers fishing between Ripogenus Dam and the base of Pockwockamus Falls.

*1.Describe the goals and objectives of each study proposal and the information to be obtained.*

The goal of the proposed study is to record existing West Branch angler use (date, time, location(s) fished and terminal gear), and catch (species, size and number). Angler use and catch presented by the applicant in the riverine areas below Ripogenus Dam is outdated. Current (daily/annual) angler use and catch needs to be enumerated and subsequently evaluated.

The last license application stated: "The salmon fishery of the West Branch has changed and grown significantly over a long period of time in response to improvements in flow and access resulting from hydroelectric developments. It is now recognized to be one of the premier salmon fisheries in the world." Ripogenus Project Application for New License dated December 1991, Volume IX, page 63]. Anecdotal information from TU members, Maine guides, and others who fish to West Branch question if this is still the case.

In order to compare (1980s) baseline conditions described in the 1991 License Application and the 1992 EIS, at least 2024 angler use and catch information beyond what the year-one study provided is necessary. In addition to providing critical fisheries information to all interested parties, a creel survey will meet goals described in the (draft) Maine Department of Inland Fisheries and Wildlife (MDIFW) Plan. In regard to Landlocked Atlantic Salmon (salmon), these goals include;

> Advocating for in-watershed land and water management practices that maintain or enhance spawning and rearing habitats for wild populations, where populations are not overabundant
>
> Continue current monitoring and assessment to be responsive to changes in abundance and condition over time
>
> **Reevaluate salmon waters that haven't been recently assessed to ensure existing regulations reflect current management goals and angler behavior**. (emphasis added**).**

2*. If applicable, explain the relevant resource management goals of the agencies or Indian tribes with jurisdiction over the resource to be studied.*

A creel survey is a standard method for determining angler use and catch from one or more waters. Typically, a clerk, either stationary or mobile, counts and when possible, interviews anglers during

predetermined dates and times. On-site counts (and interviews) are more practical and robust than other possible methods such as aerial, on-site volunteer (angler) boxes with "fill-in" forms or "mail-in" surveys that proved inadequate in the year-one recreational study. Creel surveys are commonly used by MDIFW and fisheries agencies nation-wide. Such a study of angler use, catch and effort lays the foundation for future licensing decisions making as well as supporting current/future State of Maine fisheries management goals. MDIFW filed a (draft) FISHERIES STRATEGIC PLAN 2021-2035, Vol I (MDIFW Plan dated November 2, 2021) that listed prioritized fisheries goals. General fisheries goals include "… Maintain healthy fish populations and their habitat. Ensure freshwater fish populations remain healthy and are sustainably managed into the future." In order to obtain the MDIFW Plan's primary goals, a number of secondary actions are required;

"Conserve native fish species, particularly those exhibiting population decline, …"

"Manage for sustainable harvest of sport fish"

"Promote and direct conservation actions, including conservation of riparian habitat, habitat restoration, and habitat connectivity targeting the state's highest priority wild native fisheries". **Brook trout and landlocked salmon are two of the native fish species referenced in the MDIFW's Plan.** (emphasis added).

There is no current, quantifiable West Branch fisheries information upon which fisheries management decisions can be based. A creel survey of the West Branch fisheries (salmon, brook trout) below Ripogenus Dam and extending downstream to Pockwockamus Falls will meet the goals stated above. This request is fully consistent with treaty obligations with the Penobscot Indian Nation to restore a sustenance fishery on the Penobscot.

*3. If the requester is not a resource agency, explain any relevant public interest considerations in regard to the proposed study*.

TU members fish the West Branch of the Penobscot regularly. For many of our members, this is one of our most favored fishing destinations, one that we endeavor to revisit every year. TU has a strong and continuing interest in the terms of the relicensing of the West Branch projects. TU's fisheries interests parallel the general public interest.

4*. Describe existing information concerning the subject of the study proposal, and the need for additional information*.

**The only creel data in the record sampled far too few anglers to be significant.** There is minimal current fisheries information for the WB between Ripogenus Dam and the base of Pockwockamas Falls. Critical data gaps exist for angler use, catch, and (riverine) location and for salmon and brook trout (trout) growth, survival and spawning history.

*5. Explain any nexus between project operations and effects (direct, indirect, and/or cumulative) on the resource to be studied, and how the study results would inform the development of license requirements*.

Since the issuance of the last license, project operations from a relatively stable base flow to a peaking operation. The changes have had negative impacts on angler use and salmon growth, abundance, choice of habitat and movement (personal observations). When compared to the baseline data used in the EIS, 2022-2023 West Branch creel surveys will demonstrate changes in angler use and effort and salmon and trout abundance (catch rates) and to a lesser degree, choice of habitat and movement. The survey should include scale samples and analysis for landlocked salmon and brook trout as was done with the

last relicensing would provide additional information on growth rates and the state of the fishery. [Ripogenus Project Application for New License dated December 1991, Volume X, Appendix C].

6. *Explain how any proposed study methodology (including any preferred data collection and analysis techniques, or objectively quantified information, and a schedule including appropriate filed season(s) and the duration) is consistent with generally accepted practice in the scientific community or, as appropriate, considers relevant tribal values and knowledge.*

The proposed creel survey should duplicate the study plans using a survey clerk as described in Ripogenus Project Application for New License dated December 1991, Volume X, Appendix C, Maine Department of Inland Fisheries and Wildlife 1986 Chesuncook Lake Progress Report No. 1, Methods paragraph, Summer subparagraph as closely as possible and develop data similar to that reported in Appendix E of the same volume of the license application. The proposed study methodology is consistent with current practice and consistent with the values of the Penobscot Indian Nation.

For the level of information desired, angler surveys should occur:

May and September – four (10h) days, ending at sunset
June -August – four (12h) days, ending a half hour after sunset

Sampling days should be divided between weekdays and weekend/holidays.

The Applicant may have retained a copy of the GNP computer program designed to input daily angler, use, catch and effort based on stratified random sampling. Use of this program would provide for a more valid comparison between the surveys conducted with the last relicensing and the requested survey.

7. *Describe considerations of level of effort and cost, as applicable, and why proposed alternative studies would not be sufficient to meet the stated information needs*.

Estimated cost is $35,000, consistent with a project of this size and importance.

The study conducted as part of the year-one recreational studies did not provide enough data to inform the relicensing process.

# Appendix Q

**Whitewater Boating Assessment Study**

**Comments**

Ripogenus Dam

Level 2/3 studies may be needed below Ripogenus Dam.

Millinocket Stream

The Level 1 study was adequate.

Stone Dam

Needs level 2/3 studies.

# Appendix R

**Aesthetics Study**

**Comments**

Less than a typical year, low survey numbers.

Brookfield was required to consult with stakeholders prior to the study and did not do so.

Numbers describing use of the Gorge Trail are deceptive. “Uriah Forest-Bulley (KA) said the users at the Upper Gorge Trail included people who drove to that parking area, enjoyed the views from the dam, and then left, so some users only used the parking area but not the trail.” [ISR Meeting Report, page 15]. TU believe that the trail is underutilized because Maine’s most dramatic gorge is dewatered except for three months out of the year except for leakage or overflow, and then only watered with 100 cfs “fishing flows” that do not materially improve the fishing.

TU strongly supports a controlled study for the gorge to determine aesthetic and whitewater opportunities.

# Appendix S

**Historic Architectural Survey**

TU has no comment.

# Appendix T

**Environmental Justice Study**

**Comments**

The Study Plan Determination included the language: "The Penobscot Indian Nation requests that GLHA form a Socioeconomic Working Group and conduct a Socioeconomics Study to assess existing socioeconomic conditions in the Projects' areas. The Penobscot Indian Nation's study would include an evaluation of existing conditions, including population, housing, economic development, public services, local energy production, and State statutes related to energy production, fiscal conditions, and infrastructure. The requested study would also describe current socioeconomic trends in the Projects' vicinity, and how measures implemented at the Projects may affect these trends. The Penobscot Indian Nation requests that the study be developed with extensive input from stakeholders to determine priorities for the use of resources with the potential to be affected by the project. To support this request, the Penobscot Indian Nation points to changes in the local economy as a result of the operation of the Projects and the associated paper mills, as well as the effects of the Projects on cultural, outdoor, and other economic opportunities in the region." [SPD, page B-47]

It is significant that: "The Penobscot Nation has inhabited the Penobscot River, including the West and East Branches, from time immemorial. This is the Nation's aboriginal domain. The Nation has never ceded its related aboriginal title to the River and its branches in any treaty and Congress has never extinguished that aboriginal title. It is the Nation's position that Ripogenus and the Penobscot Mills Projects, located on the West Branch of the Penobscot River, occupy federal lands, the Penobscot Reservation." [PIN Pre-application Document Comments dated October 12, 2021, page 1].

The Study Plan Determination approved the PIN request with modifications [SPD, page A-3] by directing a Socioeconomic Study/Environmental Justice Analysis [SPD, page B-47 and subsequent]. The PIN filing had gone on to say: "The PIN also has concerns of Environmental Justice surround the continued operation of the projects, as they may disproportionately affect minority and low-income people living in the region. The PIN asks that FERC staff provide guidance to the stakeholder as to the environmental justice concerns at the project, any recent changes in the FERC NEPA analysis that may or may not include sections on environmental justice, and how they could be related to these projects. [PIN PAD Comments, page 2].

Page T-1 Brookfield neglected to include this information in paragraph 1.2. Background.

Page T-2 Brookfield took the narrowest possible interpretation of the Study Plan Determination "As required in the May 13, 2022 SPD, the study area is defined as the geographic area within 1 mile of the FERC Project boundaries for the Ripogenus and Penobscot Mills Projects." The study then only considered communities physically located within the project area, essentially the shores of the West Branch of the Penobscot between the Ripogenus and Penobscot Mills projects and their impoundments. Limiting the scope to this narrow interpretation rather than to the communities that are impacted by what occurs in this area thwarted the intent of the PIN and the SPD.

**TU asks that FERC direct accomplishment of a modified study with clarifying language specifying inclusion of the Penobscot Indian Nation and the effects of mill closures on them in terms of environmental justice. Justification: 18 CFR 5.15(d) paragraphs (c)(1)–(4) "(1) Approved studies were not conducted as provided for in the approved study plan;"**

Christopher Howe, Kingfield, ME.
Ferc comments

My name is Christopher Howe and I'm the river manager for North Country Rivers Penobscot. I have been guiding rafts on the west branch since 2009. I'm an avid user of the waterway and spend more time on the whitewater of the west branch, professionally and recreationally than most users. I as well, have been residing at Big Eddy Campground April to October for the last 10 years.

When it comes to the whitewater boating opportunities between rip dam and McKay station the data presented in Millinocket in early May only covered what the river is like at high flows 2000cfs and above. There was no information presented on what the boating is like at flows between 100cfs and 2000cfs. I find this very concerning because this is the flow range that I believe, based off my 13 years of experience kayaking and rafting in this reach. would make the section of river accessible to the largest group of whitewater boaters. the study reports class IV/V big water conditions at flows 2000cfs and higher, these high flows significantly reduce the number of users comfortable paddling that sort of water. Brookfield has repeatedly stated that this section of river is a dangerous class V torrent that is unsuitable for whitewater recreation. This statement shows a profound lack in truly understanding the boating opportunities below the dam. Basing a comprehensive study off of the number of surveys received is negligible and inadequate. This complete lack of data on the low range of flows between (100cfs-2000cfs) in itself should dictate that a lvl II and III Whitaker study be conducted.

The value of Millinocket Stream cannot be overstated. If flows weren't diverted away from Millinocket Stream it could be utilized by outfitters In Millinocket to facilitate quick half day outings very close to town, which in turn could be lucrative for the outfitter. This stream as well as below Stone Dam, if given proper flows could support the local economy by diversifying options that whitewater guests could choose from. Currently Millinocket outfitters are only able to offer class IV/V rapids for rafting and inflatable kayaking compared to the class II/III rapids of Millinocket stream.

When analyzing the data presented about the dewatered section of the Penobscot below Stone Dam. It does not take a lawyer to know that there is no formal information to work with. What we do know is that there is no direct way for the public to know what water flows are below Stone Dam, and that access to the put in for the river below the dam is closed to the public. The fact that only 2 surveys were completed and 1 YouTube video was presented clearly points that a Whitaker II and III should take place on the Penobscot below stone dam.

The data presented about total users between Rip Dam and Debs Falls is heavily skewed in the negative because the study did not include informal access sites up and down the entire river corridor. These sites are heavily used by a more diverse group, because the informal sites allow access to flatwater, quickwater, and class II, III, IV rapids opposed to the class V rapids directly below McKay Station. I think this study, in order to show true usage of the river, needs to be amended to include all formal and informal access sites from Rip Dam to the Grant Brook Road Bridge.

I personally manage 7 to 8 full time employees at North Country(May-Oct). Our business is located at Big Moose Inn, which in turn brings guests to their cabins,

campground, and restaurants. Big Moose Inn has an even larger staff of house keepers, cooks, bartenders, waitresses, and grounds workers whose jobs could all be in jeopardy if any major changes to the current flow regimen were made.

I can think of 18 businesses that directly generate revenue from current flow regimens below McKay Station, and then numerous more private fishing guides who operate on the river. If you were to include businesses that are indirectly impacted, the list could spread to every summer business in Millinocket. Currently the commercial rafting business brings 5000-7500 people per year when averaged out over the last 10 years. If we look back 30 years in the history of rafting the Penobscot there are periods were the rafting companies drew 20,000-30,000 people of year during the era of the Big A Dam controversy and the paper mill. It would be short sighted for the current regimen to be changed to a point where the river could not support a similar volume of rafters in the future.

Chesuncook Lake is a man made lake created as an impoundment for power generation and should continue to be used as such, especially when foreign power companies are bulldozing the Maine forests to bring in Hydro Power.

Considering the dam was built in 1917, and now we are half way through 2023. this re-licensing should heavily consider the possible impacts of climate change and how that is going to effect water management of Chesuncook Lake in the future, the safety of the residents below, and what measures need to be taken to mitigate the risk of severe flooding or catastrophic failure of this 93 foot tall, 107 year old, concrete and wooden dam that holds back Maines 3rd largest lake.

I’m left wondering if this dam is even capable of surviving until the next relicensing around 2050. Which would leave the dam at 132 years old.

I think we need an integrity study conducted on Brookfield to determine how accurate the flows are presented on their website and why they don’t present historic flow data to the public. A 3rd party river gauge and tracker should by installed by USGS to keep GLHA honest.

I greatly look forward to collaborating with all
Parties involved to come to the most informed, fair, environmentally justified, and profitable solutions to help make room for the Katahdin Region to grow from the glory days of the paper mill over the next 30 years.

Kimberly D. Bose, Secretary
Federal Energy Regulatory
Commission 888 First Street, N.E.
Washington, DC 20426

July 6, 2023

**RE: Comments and Study Requests regarding the Maine Department of Inland Fisheries and Wildlife filing of June 30, 2023 for the Ripogenus Project (FERC No. 2572-133)**

Dear Secretary Bose:

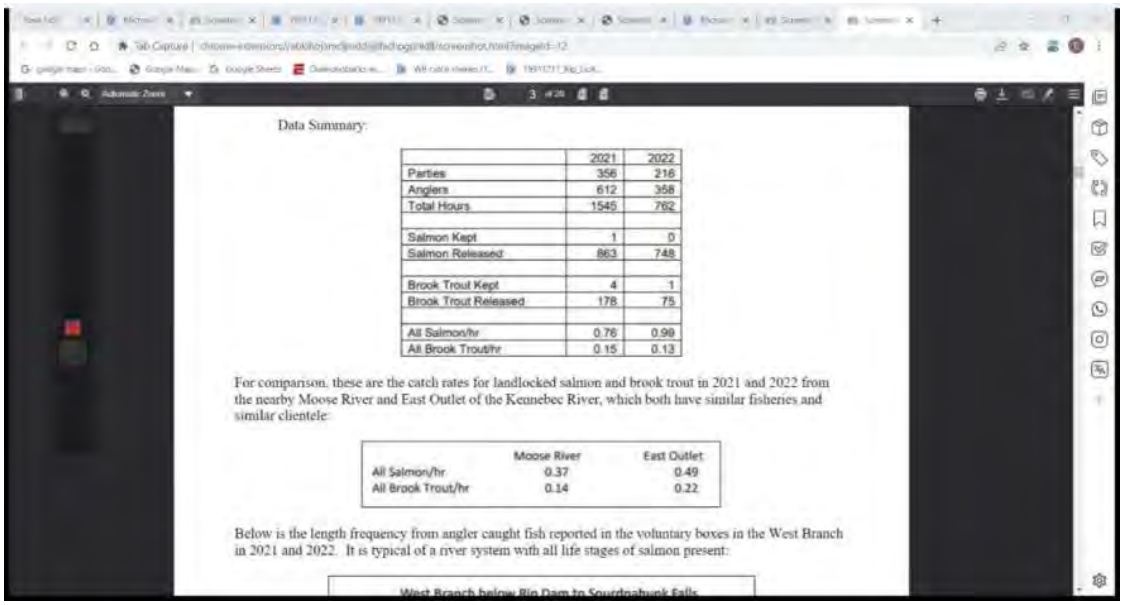
The Maine Department of Inland Fisheries and Wildlife (MeDIFW) comments of June 30, 2023 speak of smelt entrainment as well as a creel survey. The smelt drift phenomena drives the West Branch of the Penobscot salmon fishery issues. However, MeDIFW's June 30. 2023 filing speaks of facts not in evidence. These claims beg further study.

While the 1991 GNP Applications notes an average annual drift of 25,000 pounds there is no evidence that significant West Branch smelt drift is presently occurring. In fact, while MeDIFW "time available" sampling collected a few smelt, data on those catches has not been provided. Recent antidotal information suggests smelt abundance is presently insignificant.

MeDIFW states that "During our May 5, 2023, site visit to the Project with FERC staff, we stopped at the Holbrook Pool area and observed many gulls swooping down to pick up smelt that were drifting downstream from McKay Station". There was no mention of smelt being collected or observed floating downstream.

Heavy rains in August, 2022 resulted in the Ripogenus Impoundment returning to full or near full pond as a result of tributary run-off. The results were stable littoral, epilimnion and metalimnion zones during August and September. These conditions are ideal for Juvenile smelt production. In prior filings the stakeholders have argued for a gradual stable drawdown that would benefit juvenile smelt and zooplankton populations. Possibly, did MeDIFW witness a start of a juvenile smelt recovery?

Alternately, I drove by Holbrook Pool hundreds of times in my studies of the West Branch. Sea gulls are carrion feeders; they are constantly searching for food exiting McKay Station. Smelt can be present but yellow and white perch and minnow species are also entrained and drift though Holbrook Pool. Insects, however, including caddis were more common. The answer to the smelt availability issue is weekly "drift net" sampling.



Studies are needed. Smelt are the major component of fisheries issues in this licensing. A few hungry sea gulls hovering over Holbrook Pool cannot be a standard in a 30 year licensing process.

MeDIFW continues with "Studies conducted by Great Northern Paper (1985 - 1989, 1999 – 2001), and by MDIFW (2021) clearly demonstrate that hundreds of thousands of smelt from the Ripogenus Impoundment drift downstream and provide forage for the resident salmon

population". In regard to current smelt abundance, nothing is "clear". The reference to the 2021 MeDIFW smelt collection is a fact not in evidence. Without smelt numbers, length, weight and net sampling efficacies, the time available 2021 studies simply demonstrate MeDIFW's work ethic and commitment to the resource and that smelt were present in some uncalibrated number for a small portion of year. These data are NOT comparable to GNP's year long 1985-1989 and 1991-2001 smelt drift net study results.

MeDIFW explained it's standing on a creel survey request and its evaluation of the present WB fishery. Sadly, MeDIFW IS UNDERFUNDED. Unfortunately, this leads to the use of biased angler survey boxes. As a management tool these data may be satisfactory. In evaluating the existing West Branch salmonid age/growth, distribution, and abundances, MeDIFW` survey boxes fail to provide the needed quantifiable information.

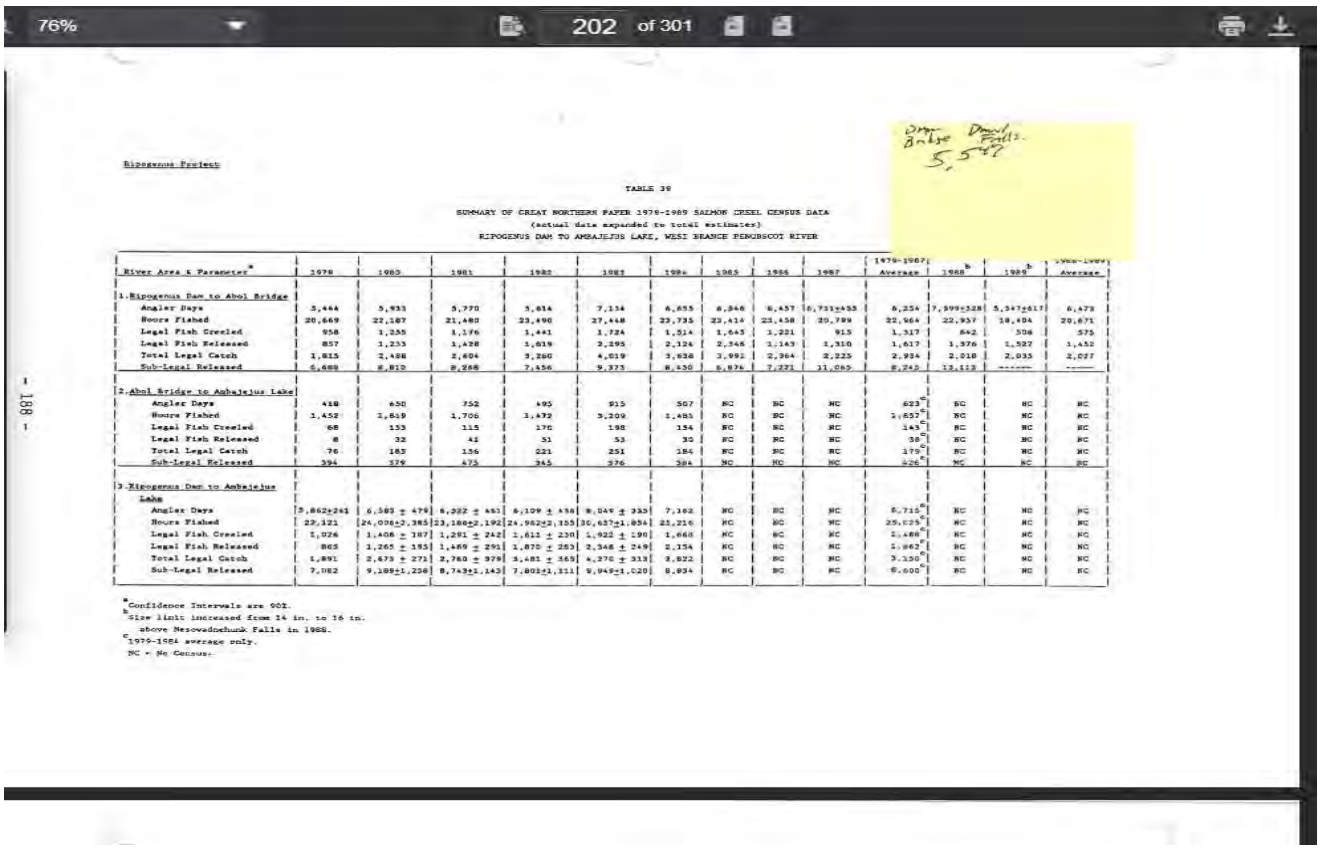
In an attempt to compare riverine fisheries, MeDIFW provided 2021 and 2022 West Branch angler survey box information. This was used in comparison between the East Outlet of Kennebec River, Moose River and West Branch as shown in the below table. Both the East Outlet and Moose River benefit for the Greenville' Region suberb management of the Moosehead salmon fishery. These reaches are popular fisheries, locating a parking spot and place to fish is difficult. The West Branch below McKay is no longer crowded with anglers and the abundance of salmon, legal or sublegal size, unknown.

Data Summary:

| | 2021 | 2022 |
|---|---|---|
| Parties | 356 | 216 |
| Anglers | 612 | 358 |
| Total Hours | 1545 | 762 |
| | | |
| Salmon Kept | 1 | 0 |
| Salmon Released | 863 | 748 |
| | | |
| Brook Trout Kept | 4 | 1 |
| Brook Trout Released | 178 | 75 |
| | | |
| All Salmon/hr | 0.76 | 0.99 |
| All Brook Trout/hr | 0.15 | 0.13 |

For comparison, these are the catch rates for landlocked salmon and brook trout in 2021 and 2022 from the nearby Moose River and East Outlet of the Kennebec River, which both have similar fisheries and similar clientele:

| | Moose River | East Outlet |
|---|---|---|
| All Salmon/hr | 0.37 | 0.49 |
| All Brook Trout/hr | 0.14 | 0.22 |



Below is the length frequency from angler caught fish reported in the voluntary boxes in the West Branch in 2021 and 2022. It is typical of a river system with all life stages of salmon present:

West Branch below Rip Dam to Spurdnahunk Falls

MeDIFW's management goals include "satisfying" anglers. Most, is not all, anglers focus on catching larger, legal-size salmon rather than 6-12" subadults. Thus, tabular information that includes "small" salmon is not much of a standard when applied to a 30 year licensing process. Recording sub-legal fish is a normal component of creel surveys. GNP 1979 – 1986 survey generally followed MeDIFW's guidelines. Clerks asked and recorded angler reports of sub-legal

fish released. The table below provides the outdated GNP creel survey results. The average fish per angler was 1.57 salmon a day. This is twice the number of West Branch 2021-2022 survey box fish per day results and provides a clear indication of the decline in the West Branch salmon fishery downstream of McKay Station associated with the change in project operation.

[b]Size limit increased from 14 in. to 16 in. above Nesowadnehunk Falls in 1988.
[c]1979-1984 average only.
NC = No Census.

The above information, including MeDIFW's plea for funding demonstrates the need for a quantitative survey of West Branch anglers and their catch. For obvious reasons MeDIFW does not want a third party involved. I concur.

I ask FERC to require a MeDIFW designed, managed, and staffed creel survey of the West Branch between Ripogenus Dam and Abol Bridge. The Licensee would provide funding. As part of this request, I also ask that the Licensee completely fund an entry level MeDIFW fishery position dedicated to the Ripogenus Impoundment and downstream West Branch. This additional staff member would be part on the Greenville Region staff and supervised by the lead biologist. The current licensing process will last for several years. Validation of mitigation and enhancement measures will last even longer. Requiring the Licensee to fund a MeDIFW West Branch staff member is reasonable as no other entity has riverine creel survey expertise.

Licensee funding of subsequent oversight of future project operations including the upstream Storage Project and its associated fisheries e.g., The Foxhole, is a likely License Article condition.

Any creel survey of the West Branch should be of MeDIFW's design with the caveat that anglers fish late into the evening. These anglers and their catch need to be counted and when possible, interviewed. In an earlier filing on November 9, 2002, I proposed a West Branch of the Penobscot River creel survey of the reach below McKay Station extending to Abol Bridge. This document is attached for the reader's convenience and is a suggestion of study design rather than a demand.

Thank you for the opportunity to comment and for your consideration of the two proposed studies.

Federal Energy Regulatory Commission
888 First Street NE, Room 1A
Washington, DC 20426. VIA Electronic Filing

**Reference: Ripogenus Hydroelectric Project (P-2572-133)**

**RE:** A Study Request and Comments on the April 23, 2023 Initial Study Report Appendix D and a request for Rainbow Smelt (Osmerus mordax) studies of their growth, age and abundance in the Ripogenus Impoundment and West Branch of the Penobscot River downstream of McKay Station

Rainbow smelt (smelt) populations of the Ripogenus Impoundment sub basins provide prey as juveniles to salmonids in the Impoundment and downstream West Branch of the Penobscot River (West Branch). Their abundance is the most important fisheries parameter in the licensing of the Ripogenus Project (P - 2572) The Initial Study Report Appendix D (ISR) fails to address United States Fish and Wildlife Service's (FWS) request for rainbow smelt collections during 2022 sampling of the Ripogenus Impoundment and downstream West Branch. Moreover, limited smelt information provided in Appendix D showed an average smelt length typical of older fish which are generally too large for most adult salmon. This is evidence of a smelt population out of balance, "top heavy" with older fish.

My filing of January 27, 2022 requested actions similar to FWS's request. This filing reviews the life history and role of smelt in fisheries of the above referenced project waters. Sampling methods of lacustrine and riverine waters are suggested. The following is a "cut and paste"

brief literature review from the January 27, 2022 filing. Literature citations can be found in the January 27, 2022 filing.

A 1981 summary by Maine research biologists Fred Kircheis (MeDIFW) and Jon Stanley (UMO Coop Fish Unit) reviewed smelt populations in Maine and other Lakes throughout the Northeast. Regarding variability in smelt population abundance/densities, they concluded that *"such fluctuation are usual and do not appear related to predator abundance, rainbow smelt fishing or disease." Rainbow smelt larvae require small zooplankton such as rotifers when they begin feeding, "unavailability of suitable size plankton might limit survival of larvae" (McCullough and Stanley, 1979)."* (Kircheis and Stanley 1981). The literature provides insight into a litany of factors determining smelt abundance and growth.

Based on extensive review of the literature, the primary reason for a reduction in larval/juvenile smelt year class is cannibalism by age II and older smelt. Smelt are known to demonstrate alternate year class strength, often resulting from cannibalism as well as variable population densities resulting from predation or loss of suitable zooplankton as forage. Stet er et al. (2007) reported cannibalism at between 38 and 95 percent of YOY year class strength. This cannibalism typically produces alternate smelt years classes where larval survival is poor the first year but strong the next year(s) (Lantry, B.F., and Stewart, D.J. 2000). He and Labar (1994) studying Lake Champlin smelt populations noted that gaps in year class strength could extend for three to five years.

Ripogenus Impoundment juvenile smelt are the critical forage item for the impoundment and West Branch salmon. During 1980 – 1989 then Great Northern Paper (GNP) sampled smelt weekly. The catch was largely larval/juvenile smelt ranging between 35 and 100 mm over time. Smelt of this size are known to be the preferred prey of salmon. GNP's 1991 Application contained references to an average annual smelt catch of 25,000 pounds. Post 1996 licensing smelt information is limited to 1999-2001 GNP collections and time available 2021 -2022 MeDIFW sampling. The ISR did not directly address the FWS request. However, Smelt collected in the 2022 electrofishing survey of the Ripogenus

Impoundment were older and generally too large to be suitable salmonid prey.

The Maine Department of Inland Fisheries and Wildlife (MeDIFW) stated their concerns with the apparent lack of juvenile smelt in their June 8, 2021 filing.

*June 8, 2021 The inland fisheries management goals for the Ripogenus impoundment and river have not changed since the last license was approved; however, there has been a significant change in the quality of the landlocked salmon fishery in both locations. The decline in salmon growth is related primarily to a surplus of salmon in the impoundment and resulting lack of smelt, the primary forage* fish.

From the literature the primary reason for smelt year-class failure is cannibalism by older smelt. However, other reasons are given: reduced abundance of zooplankton, namely rotifers; reduced, fluctuating, or lost littoral zones; and depressed metalimnion areas are referenced along with turbidity. Over predation by salmonids can exist with Lake trout and salmon interaction but is rarely mentioned with a single salmonid species over an extended time period (five plus years), landlocked salmon in this case. MeDIFW has been attempting to rejuvenate the Ripogenus salmon population for five plus years, well past the length of any recorded year classes failure. While over predation of juvenile smelt by adult (>12") salmon may well be part of the problem, it cannot be the only cause. A likely second important factor is lake level management issues. These factors need to be investigated.

Currently there are no quantifiable Ripogenus smelt data in the post 1996 record (Incomplete 1999-2001 GNP data were recently added). The Licensee's search of MeDIFW files produced 2021 and 2022 West Branch smelt "drift net" catches. MeDIFW has limited resources and cannot be expected to travel to the West Branch on a regular basis. MeDIFW data, were based on "time available" and lacked river flow,

volume of water sampled and time "fished". No smelt length or weigh measurements were provided. Simply put, these data are not comparable to 1980-1989 and 1999-2001 GNP collection. Other than smelt were present in the West Branch in brief periods of 2021-2022, there are no quantifiable comparisons between GNP data and recent MeDIFW collection. The status of the Ripogenus Impoundment and Downstream West Branch smelt population is unknown and critical in Water Quality Certification and fisheries management.

A study is needed of the Ripogenus smelt population(s) focusing on spawning, egg survival, fry escapement, zooplankton availability with the emphasis on rotifers, and survival of smelt though their first year. Smelt contribution, if any, to "drift" in the West Branch downstream of McKay Station needs to be determined.

1.Describe the goals and objectives of each study proposal and the information to be obtained.

The goals of this study are to determine the status of the Ripogenus smelt population by following an age class from egg to Age I and determine any contribution of this cohort to the West Branch downstream of McKay Station and its salmonid fishery.

2. If applicable, explain the relevant resource management goals of the agencies or Indian tribes with jurisdiction over the resource to be studied.

Rainbow smelt are the primary food source of Ripogenus Impoundment and Downstream West Branch salmonid fisheries. MeDIFW has noted the paucity of smelt in these waters. These apparent (but undocumented) shortages have resulted in failures to meet fisheries management goals.

3. If the requester is not a resource agency, explain any relevant public interest considerations in regard to the proposed study;

I am a private individual who worked for then GNP and was responsible for (West Branch) fisheries study deigns, data collection and analysis and coauthoring the current Ripogenus and North Twin Projects FERC License application. I remain interested in the WB fish and aquatic communities and fish there often. Returning the Ripogenus Impoundment and downstream West Branch fisheries to their 1996 status is surely in the public interest. Additionally, this request parallels an US Fish and Wildlife request found in Fish Assemblage Study Report Appendix II*, USFWS Comments on Draft Fish Assemblage Study Plan, August 4,2022. The USFWS request was not implemented because* "FERC did not require smelt spawning or drift surveys in the SPD" (Appendix P 114).

4. Describe existing information concerning the subject of the study proposal, and the need for additional information.

There is NO existing fisheries information, thus this is NOT an additional information request. Studies provided by the Licensee are old PRE-Peaking and thus, irrelevant. The impoundment and water level management are no longer managed for the steady needs of paper making. Flows and lake levels are now managed for widely variable market driven power needs. There is no current (quantifiable) information on the Ripogenus smelt population(s). The current spawning success, age class structure, food availability is unknown as is "smelt drift" below McKay Station. Critical data gaps exist and information gathered will help FERC staff balance the competing use of the resource.

5. Explain any nexus between project operations and effects (direct, indirect, and/or cumulative) on the resource to be studied, and how the study results would inform the development of license requirements.

The Licensee has changed project operations from a relatively stable base flow used in papermaking to a peaking operation with a concurrent change in lake level management to more common and drastic drawdowns. This change in operations has had a direct impact on smelt life history as well as on angler use and salmon growth, abundance, and possibly spawning success. The continuing energy market driven peaking operations and corresponding earlier and more drastic drawdown will reduce, at a minimum, juvenile smelt availability to lacustrine and riverine salmonid populations, namely salmon.

6. Explain how any proposed study methodology (including any preferred data collection and analysis techniques, or objectively quantified information, and a schedule including appropriate field season(s) and the duration) is consistent with generally accepted practice in the scientific community or, as appropriate, considers relevant tribal values and knowledge.

This is a multigoal study: description of the Ripogenus juvenile smelt population and subsequent export into the West Branch below McKay Station.

A Ripogenus Impoundment tributary such as Ragged Stream should be confirmed as providing suitable smelt spawning escapement. Subsequent spawning success would be measured following methods described in a recent MeDIFW Report, **Developing Catch Indices for Rainbow Smelt Fry Outmigration on North Brook, Lily Bay Moosehead Lake,** By:Stephen Seeback, Moosehead Lake Region, including age information on spawning adults.

**The distribution and timing and outmigration of larval juvenile smelt would be followed by bi-weekly (vertical) plankton tows as**

**well as horizonal larval smelt sampling with approximate methods e.g., oblique plankton trawls beginning in the shoreline littoral area continuing out into pelagic** epilimnion/**metalimnion zones (as the impoundment stratifies). Lacustrine sampling should continue into October.**

**Riverine sampling. Smelt "drift" into the West Branch, is the other "end" product of this study request. It is the Ripogenus Impoundment juvenile smelt population that supported the historic West Branch salmon population. The presence of a relatively constant (juvenile) smelt drift is the reason this fishery existed. Today, smelt drift has declined as has the salmon fishery. GNP 1991 described weekly sampling protocols and these methods should be followed**

7. Describe considerations of level of effort and cost, as applicable, and why proposed alternative studies would not be sufficient to meet the stated information.

The burden of determining the status of the Ripogenus smelt population rests with the Licensee and NOT MeDIFW. The cost will be moderate when compared to the Fish Assemblage study and the result(s) will fill several data gaps. Without a description of lacertine smelt abundance and downstream smelt drift information, FERC staff will lack quantitative information on which to balance the competing users of the resource. There is simply no other method of evaluating smelt populations other than field sampling over an extended time period.

Ideally MeDIFW would be fully funded, including money for additional staff, to carry out smelt component of the study.

Collection and identification of zooplankton would be the Licensee's responsibility as would basic water quality information (temperature and dissolved oxygen).

Thank you for the opportunity to comment and for your consideration of the proposed study.

**Reference: Staff Comments on the Initial Study Report and Initial Study Report Meeting Summary**

Dear Mr. Dorman:

We have reviewed Great Lakes Hydro America, LLC's (GLHA) Initial Study Report (ISR) and associated draft study reports for the Ripogenus Hydroelectric Project (Ripogenus Project) and the Penobscot Mills Hydroelectric Project (Penobscot Mills Project), filed on April 24, 2023. We also attended the ISR Meeting held May 2-4, 2023, and the Environmental Site Review held May 5, 2023, and have reviewed the ISR Meeting Summary filed on May 22, 2023.

We provide our comments on GLHA's ISR and associated filings (i.e., study reports and ISR Meeting summary) in Attachment A. Unless otherwise noted, please address the comments in Attachment A in the Updated Study Report, which must be filed by April 22, 2024.

If you have any questions, please contact Allan Creamer at (202) 502-8365, or via email at allan.creamer@ferc.gov.

Sincerely,

STEPHEN BOWLER Digitally signed by STEPHEN BOWLER Date: 2023.07.06 08:45:58 -04'00'

Stephen Bowler, Chief
South Branch
Division of Hydropower Licensing

# ATTACHMENT A

## STAFF COMMENTS ON THE INITIAL STUDY REPORT AND INITIAL STUDY REPORT MEETING SUMMARY

### *General*

1. During the Initial Study Report (ISR) meeting, and as documented in the ISR Meeting Summary filed May 22, 2023, several stakeholders expressed concern over the lack of consultation in developing and implementing the study plans. For example, as we noted, the Environmental Justice Study was to be conducted in consultation with the Penobscot Indian Nation and other relicensing stakeholders, which did not occur. The Maine Department of Marine Resources (Maine DMR) expressed concern with the lack of consultation regarding the methodology used for the Upstream American Eel Passage Study. Finally, while the Maine Council of Trout Unlimited (Maine TU) filed comments on the proposed Fish Stranding Study Plan,[1] the final study plan was not communicated to Maine TU or other key stakeholders prior to the study's implementation.

   The Study Plan Determination (SPD) issued May 13, 2022, specifically required that the Environmental Justice Study be conducted "in consultation with the Penobscot Indian Nation and other relicensing stakeholders." As we note above, this consultation did not occur during the first year of studies. To ensure that the Environmental Justice Study is completed in accordance with the approved study plan, conduct consultation with the Penobscot Indian Nation and other interested relicensing stakeholders during the second year of studies.

   With regard to general consultation with stakeholders in the Integrated Licensing Process (ILP), section 5.1(e) of the Commission's regulations states that the purpose of the ILP process is to "provide an efficient and timely licensing process…" To ensure an efficient process, the ILP is designed to increase public participation in the pre-filing consultation process, including the development and implementation of requisite study plans.[2] The ILP can be most effective when, where appropriate, the final details of study design (e.g., methodologies) are worked out in consultation with the stakeholders, and that final study plans are provided to the stakeholders, prior to the study plan's implementation. To meet

[1] *See* for example, https://elibrary.ferc.gov/eLibrary/filedownload?fileid=90D0F7B7-4841-C14B-9EC9-836B8D600000.

[2] *See* sections 5.12 and 5.13(b) of the Commission's regulations.

this intent, please manage the second study season with a more proactive and inclusive approach to stakeholder consultation.

***Historic Operations Data Assessment Study***

2. The results of the Historic Operations Study were presented during the ISR meeting. The presentation included graphical representations of lake levels and flows through the Ripogenus and Penobscot Mills Projects' developments. GLHA filed the operations data in electronic format on May 22, 2023, along with the ISR Meeting Summary. To assist us and other stakeholders in comparing actual operational releases to the licensed releases, as well as better understanding the details of how the projects are operated, please revise the excel spreadsheets for each of the projects' developments to correlate the historical hourly flow data with the licensed flow requirements at the time.

***Operations Model Study***

3. During the ISR meeting, and as documented in the ISR Meeting Summary, Maine TU raised concerns regarding the results of the validation run of the Operations Model. Maine TU indicates that, for the calendar year 2020, the modeled results do not line up well with the actual reported impoundment levels and releases for the Ripogenus Project.[3] To address concerns about the CHEOPS (Computer Hydro Electric Operations and Planning Software) model and to improve the outcome of the second year of the study, which involves developing alternative operating scenarios to model, GLHA raised and the group discussed the concept of GLHA establishing a working group for the operations modeling. Establishing a working group could be beneficial to this process. If such a group is established, a technical work session could be convened to familiarize the members of the working group with the CHEOPS model, including how it works, as well as the models' assumptions and limitations. Such an approach could help to improve understanding of the model and ensure that all reasonable alternatives identified by stakeholders are modeled during the second year of studies.

[3] Figure 1-101 in Attachment 1 of the Operations Model Study Report shows that the model simulated less outflow from the Ripogenus Project than the reported outflow. This results in simulated elevations that are higher than reported elevations in the Ripogenus impoundment.

***Fish Stranding Study***

4. GLHA's Fish Stranding Study Report included in the ISR and the fish stranding report filed by Maine TU on October 19, 2022,[4] show that dropping flow at McKay Station from generation releases to 510[5] cubic feet per second (cfs), when the generating units trip offline, results in fish and macroinvertebrate[6] stranding, and mortality. As indicated in the ISR Meeting Summary, we noted at the ISR meeting that, while the methodologies and geographic scope of the two studies varied, the results of both studies show that stranding and mortality of aquatic organisms is occurring during the unplanned outages at McKay Station. We suggested that the next step is to determine the frequency and significance of the fish stranding and mortality, and if the events warrant mitigation. To this end, we discussed the possibility of GLHA reviewing the results of the two studies in consultation with the U.S. Fish and Wildlife Service, Maine Department of Inland Fish and Wildlife (Maine DIFW), Maine TU, and other interested stakeholders to determine: (a) what effect, if any, the unplanned outages at McKay Station have on the fish and macroinvertebrate populations in the West Branch of the Penobscot River; and (b) if appropriate, identify potential ways to address fish and macroinvertebrate stranding and mortality downstream from McKay Station.[7]

---

[4] *See* https://elibrary.ferc.gov/eLibrary/filedownload?fileid=086DE661-0456-C845-A09B-83F0C9000000.

[5] The existing license requires, and the approved study plan stipulates, that the minimum flow of 400 cfs be passed in the case of a station trip (i.e., generating units tripping off-line). However, due to the installation of a new breaker system for the generating units at McKay Station, the low flow now passed during a station trip is 510 cfs.

[6] Macroinvertebrates are animals lacking a backbone that are large enough to see without the aid of a microscope. They may be aquatic or terrestrial; the aquatic organisms often being larval or nymph forms of terrestrial species. Aquatic macroinvertebrates include annelids (segmented worms), mollusks (e.g., freshwater mussels), arthropods/ crustaceans (e.g., crayfish), arachnids (spiders), dragonflies and damselflies, stoneflies, mayflies, caddisflies, true bugs, beetles, true flies, and others.

[7] Examples of such measures could include: (a) identifying a minimum flow that reduces the amount of stranding that is occurring; (b) a battery back-up system that supplies power to a unit or units at McKay Station when the main power source is unavailable, which would reduce the amount of time at the low flow; (c) automating a gate at Ripogenus Dam so that when McKay Station trips offline a gate opens to release a preset minimum flow to the West Branch of the Penobscot River downstream from Ripogenus Dam; etc.

***Instream Flow and Habitat Assessment Study (Stone Dam)***

5. The Instream Flow and Habitat Assessment Study for the West Branch of the Penobscot River downstream from Stone Dam shows that a flow of 300 to 400 cfs would increase wetted area and substantially improve the availability and suitability of habitat for brook trout (juveniles and adults), land-locked salmon juveniles, and macroinvertebrates in the reach.[8] The model estimated that habitat suitability for juvenile and adult brook trout, as well as juvenile land-locked salmon would increase with flows up to 500 cfs (juvenile trout and salmon) and 700 cfs (adult trout), before declining. Habitat suitability for land-locked salmon adults would increase with flow up to the maximum flow of 2,000 cfs, and habitat for macroinvertebrates would increase with flows up to 1,000 cfs before declining. Also, Maine DIFW expressed interest in establishing a put-and-take brook trout fishery, as well as improving habitat conditions for land-locked salmon, in this reach. Given these results indicating the fishery potential in the reach, we asked during the ISR meeting, as documented in the ISR Meeting Summary, about the fishability (i.e., the potential for anglers to safely wade and fish) of the reach at the range of flows modeled (0 to 2,000 cfs). Please address the suitability of the reach for angling under the range of flows studied, and identify the flow (or flow range) where the reach is no longer suitable for wading, in the final Instream Flow and Habitat Assessment Study (Stone Dam) Report.

***Common Loon Management Plan Assessment Study***

6. During the ISR meeting, as documented in the ISR Meeting Summary, Maine DIFW asked whether the operations model can be used to evaluate whether or not Ripogenus impoundment levels could be maintained to support loon nesting activities. We stated that we thought that the model could be used for this analysis, but suggested it could be difficult to achieve, based on water use balance considerations. To clarify our statement, the model could be used to evaluate whether Ripogenus impoundment levels can be maintained to support loon nesting. However, balancing competing uses of the system's water to achieve stable water levels during the loon nesting period in Ripogenus impoundment

[8] The actual suitability of habitat gained with increased flow, however, would be limited by water temperatures in the reach during the summer months. Water temperatures in 2022 averaged about 23 °C (73 °F), with a range from around 18 to 28 °C (64 to 82 °F). These temperatures would be more conducive to the year-round survival of land-locked Atlantic salmon than to brook trout, which require water temperatures well below the observed water temperatures to survive. *See* GLHA's Downstream Water Temperature and Dissolved Oxygen Study Report.

could be challenging. Nonetheless, please work with Maine DIFW to identify and model alternative operating scenarios that could improve loon nesting success on the Ripogenus impoundment.

***Recreation Study***

7. The approved study plan required that provisions be added to the Recreation Study for: (a) semi-structured interviews; or (b) focus groups comprised of interested, individual recreation users (e.g., whitewater boaters and anglers), commercial outfitters, and camp owner/operators. The generally accepted practice in the scientific community for qualitative interviews for recreation needs assessment involves the preparation of an interview script, which is then read by an interviewer at a specific location to garner input from recreationists in a semi-structured, relatively consistent manner. While the ISR contains useful recreation use data, the recreation study plan, as required, was not followed, nor did the study follow generally accepted scientific practice. Because these data were inconsistently collected during the 2022/23 study season, adding this component to the second (2023/24) year of studies would provide a mechanism to obtain consistently collected information at some of the informal and formal recreation sites at the projects. Additionally, due to the low number of survey responses for the Penobscot Mills Project and to subsequently increase the number of surveys, please consider: (a) reinstalling QR code survey kiosks with instructions that are clearer than those used in the first year; (b) include a textual link to the online survey at each kiosk; and (3) include a link to the survey on Brookfield's relicensing website.

***Aesthetic Study***

8. GLHA collected baseline information from key observation points (KOPs) at the Projects as part of its aesthetics study. However, the KOP evaluation team did not include representatives from stakeholder groups, as required in the approved study plan. Adding non-GLHA representatives to the study design will provide a means to learn what KOPs are important to a larger audience. Therefore, expand the evaluation team for this study to include interested representatives of Maine Bureau of Parks and Lands, American Whitewater, Appalachian Mountain Club, Camp Owners Associations, and other interested stakeholders.

Washington, D.C. 20426

**RE: Comment on Initial Study Report, Ripogenus Project (FERC No. 2572) and Penobscot Mills Project (FERC No. 2458)**

Dear Secretary Bose,

These comments are in response to the Initial Study Report, submitted to FERC on April 24, 2023 by Great Lake Hydro America, LLC (GLHA). The Bureau has been an active participant in the combined Integrated Relicensing Process (ILP) for these Projects, providing input to the development of the study plans for the Recreation and Aesthetics Studies. We also attended the in-person ISR meeting in Millinocket on May 4, 2023, when the Recreation and Aesthetics Studies were discussed. Based on that participation and on the Year 1 study results, we offer the following comments on study deficiencies, recommendations to address those deficiencies (including modified implementation of the study plans) and requests for new information gathering.

## Comments on Study Deficiencies and Recommendations to Address Those Deficiencies, Requests for Modifications of Approved Studies

Recreation Study

*Recreation User Survey:* The number of completed recreation surveys is very small for both Projects, and in particular for the Penobscot Mills Project (34 total), where no more than 10 recreation users were surveyed at any site. The Bureau considers the low number of survey participants substandard, particularly given the amount of use of the sites, as documented by the Recreation Use Assessment portion of the study, and an indication that the passive methodologies used (with no in-person contact with recreationists in the field) was not adequate. As a result, this portion of the recreation study is deficient.

Although survey kiosks with QR codes and the on-line survey were available through February 2023, the ISR reports only on data collected through January 10, 2023; reporting on remaining survey data has been postponed to the Updated Study Report. However, as documented in the correspondence for the Recreation Study (Attachment 11 of the study report), the contractor conducting the recreation study was concerned about atypical winter conditions, hampering opportunities for snowmobiling and ice-fishing, in early 2023. The atypical conditions persisted, resulting in a significantly delayed season and likely reduced recreation activity. Given these facts, the recreation survey for the winter season should be supplemented with additional data collection.

The ILP schedule does not permit a full second-year visitor survey to be conducted, since the summer recreation season will have passed before FERC issues a Study Plan Determination. Nevertheless, we believe it is worthwhile to conduct additional recreational surveys during the fall and winter of 2023-24, after FERC issues the Study Plan Determination. ***We therefore request that GLHA conduct a Year 2 fall and winter survey as the ILP schedule permits, and supplement (or replace) the use of kiosks and online surveys with the addition of in-person surveys, to obtain more representative data. (Note: the potential addition of in-person surveys is the only modification of approved Study Plans we are requesting.)***

*Recreation Site Boat Launch Usability Assessment – Ripogenus Impoundment*: The text in the relevant portion of the ISR (pp. P-158 - P-161) is confusing and doesn't fully align with the associated graphs (Fig. 5.25 and Fig. 5.26). The elevations cited in the text for Caribou Lake Put-in and Chesuncook Dam Point Boat Launch correctly indicate that the full pool elevation is ~ 941.6 ft. However, the text refers to the "high water mark" when presenting the field analysis of the length of the ramps that is usable and uses that as the basis for the minimum usable elevation calculations and the slope lines presented in the figures. (The "high water mark" elevations are not provided in the text, only in the formulas embedded in the graph .) It is not clear why the "high water mark" elevations were used, nor why that elevation would differ between the two sites that are on the same impoundment. Also, the method used to determine the elevation at the furthest usable extent of the launches (80 ft. at Caribou and 150 ft. at Chesuncook Dam Point) is not explained. The differences between the "high water mark" elevations presented and the full pool elevation (-2.6 ft at Caribou and -1.6 feet at Chesuncook Dam Point) make it more difficult to interpret the results. ***Therefore, we request that the minimum usable elevation calculations and graphs be revised in subsequent reports using the Ripogenus impoundment full pool elevation.***

One of the primary metrics the Recreation Study uses to measure and present launch usability is a 2010-2022 Memorial Day to Labor Day duration analysis, indicating the percent of time during that 13-year period each launch was usable based on the minimum usable elevation and impoundment elevation data. While this multi-year data is relevant, given the year-to-year variability in impoundment elevation, and the fact that multiple dry/low-water years may occur is succession, we believe an analysis that focuses on launch usability in individual years is more meaningful. An indication of this can be deduced from the text on page P-161, that indicates the Chesuncook Dam Point boat launch was unusable at least part of the Memorial Day to Labor Day season five of the seven years between 2015 and 2021. As an example, hourly impoundment elevation data (provided to ILP participants separately by GLHA) indicates the

Chesuncook Dam Point launch was unusable 82 out of 99 days between Memorial Day and Labor Day 2021. It would be useful to know the first day after Memorial Day and the total number of days each launch was unusable during each year the impoundment elevation fell below the minimum usable elevation, and the average number of such days over those seasons. ***Therefore, we request these additional analyses focused on individual years be conducted and included for both Ripogenus impoundment launches in subsequent reports.***

Regarding the graph figures, we request the following modifications, which we believe would improve stakeholder's understanding of the final study report: 1) clearly mark with a horizontal line the minimum elevation at which each facility is usable, *with 3 feet of water depth* (the "Elevation Boat Launch is Unusable" label on Fig. 5.25 is mislocated in this regard, and disagrees with the text), and 2) add a legend for the lines on each graph (it is not clear from the labeling what the solid lines are intended to represent, perhaps actual (vs. calculated) launch elevation/slope?).

*Boat Launch Usability Assessment - Fall Season*: In our comments on the Proposed Study Plan (2/22/22), we stated our interest in verifying boat access on the Project water bodies through the ice-free season (generally May through November). In particular, it is critical to include the fall season in evaluating access to the Ripogenus impoundment, given the importance of the fall angling season (closing Sept. 30) for landlocked salmon on Chesuncook Lake and the West Branch upstream of the lake. As documented in the PAD, this is a "high-quality and important fishery in Maine, and a primary source of recreation in the area." There are also fall fishing opportunities for landlocked salmon and other coldwater species on the North Twin and Millinocket Lake impoundments, which are open to fishing all year. However, the boat launch usability assessment component of the Recreation Study references a Memorial Day to Labor Day recreation season (p. P-161) and bases the calculations of the percent of time the launches were usable on that period. ***Therefore, in order to fully meet the study objective to "…assess the accessibility and useability of select Project boat launching facilities provided at the FERC-approved Project recreation sites…" the Bureau requests that the period of analysis for the boat launch usability assessment be extended through the fall season (November) in subsequent reports.***

*Interviews or Focus Groups*: In response to requests from BPL and others, FERC in the Study Plan Determination (5/13/22) recommended use of "…interviews or focus groups with interested individuals representing recreation user groups (e.g., whitewater boaters, anglers), commercial outfitters, and campground owner/operators" (p. B-41). No interviews or focus groups have been conducted or scheduled; therefore, the study was not conducted as provided for in the approved Study Plan. These qualitative methods can provide valuable additional information and fill gaps in information collected through the Recreation User Surveys. They have additional importance in this case, given the low number of Recreation User Surveys completed, as noted above. ***Therefore, the Bureau requests that interviews or focus groups be conducted as part of the Year 2 data collection for the Recreation Study.***

**Requests for New Information Gathering**

The Bureau is not requesting entirely new studies. Rather, we believe certain additional information gathering within the context of or as an extension of the approved Year 1 studies is

appropriate, as detailed below. We are requesting a new, focused, Whitewater Boating Study, as a next step in investigations on the West Branch below Stone Dam; however, the potential for this study was mentioned by FERC in the Study Plan Determination, and we therefore consider it an extension of the existing Study Plan rather than an entirely new study.

Recreation Study

*West Branch Below Stone Dam - Recreation Access Assessment*: In the Bureau's comments on the Proposed Study Plan (2/22/22) we requested that the Recreation Study include evaluation of recreation access to the West Branch below Stone Dam and of a potential portage around Great Falls. Although this was not required in the Study Plan Determination, we believe the results of the Whitewater Boating Assessment Study and the Instream Flow and Habitat Assessment of West Branch Downstream of Stone Dam Study provide significant new information that justifies this requested evaluation.

This river reach was included in the Whitewater Boating Assessment Study, but that "Level 1" study was limited to existing information and paddler knowledge. As such, the report describes only the current very limited access and boatable flows (based only on spill and seepage), and bases boating opportunity and experience information on interviews with only two individuals. That study report states "this reach offers little value regionally" due to limited access, flow availability and unfavorable rating of the experience provided (due to the preceding factors). However, the paddler interviews conducted for the Whitewater Boating Assessment Study highlight the Class II to IV whitewater available with sufficient flows, easily accessed in contrast to the more remote West Branch reach below McKay Station. Moreover, the whitewater paddling community remains strongly interested in the potential for enhanced opportunities on this reach of river, which could result from the ILP if limited access and flow availability are addressed in the new license.

Also, although analysis of alternative minimum flows has not yet been conducted, the minimum flows under consideration (as reported in Appendix F – Instream Flow and Habitat Assessment of West Branch Downstream of Stone Dam Study) and, more specifically, that appear to maximize most habitat goals generally coincide with the 700-1000 cfs minimum boatable flows thus far indicated by the Whitewater Boating Study. Lastly, access for anglers who would take advantages of MDIFW's proposed put-and-take landlocked salmon and brook trout fishery have not been addressed.

This river reach flows through the Backchannel Wildlife Management Area, which is managed by GLHA and open to the public. Based on existing gravel roads to and through the WMA and associated connections to paved public roads (e.g., State Route 11), public road access to the reach would likely cross the WMA. However, information is lacking on the extent and condition of the current gravel road system that could provide access to the river, and to likely put-in and take-out sites, which are also within the WMA.

***Therefore, we request that the Recreation Study in Year 2 include additional information gathering to assess potential improved access to the reach for both anglers and paddlers and a potential portage around Great Falls. The Bureau specifically requests, given that the***

***minimum flows required in the new license may result in boatable flows on this reach and an enhanced fishery, that the Recreation Study be modified to include:***

- ***assessment of public road access to the channel,***
- ***assessment of potential put-in locations near Stone Dam and take-out locations on the channel upstream of Shad Pond for paddle-craft, and***
- ***assessment of a portage route around Great Falls.***

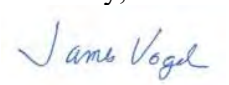
Whitewater Boating Assessment Study

*Potential Means to Provide Boatable Flows in West Branch below Stone Dam*: The Whitewater Boating Assessment Study report states that "there are no gates that could be used to provide controlled flow releases into this reach" (p. Q-12), while later stating that "releases are typically made by deflating the inflatable dam" (p. Q-50). GLHA, in response to comments on the Proposed Study Plan, as recorded in the Revised Study Plan, stated that the pneumatic flashboard system at Stone Dam is not capable of consistently providing the precise or sustained flows necessary for conducting a controlled flow study; FERC confirmed this in the SPD. However, it is not clear to us whether that system could provide suitable recreation flows, where precision is not required. Although potential increased minimum flow in the reach is being investigated, the Whitewater Boating Assessment Study assumes boatable flows would be available only during spill events. ***In order to more fully meet the goal of the Whitewater Boating Assessment Study to "…use existing hydrologic and Project operational data to assess the frequency and timing of acceptable paddling flows under current and proposed Project operations…" we request that the licensee provide additional information to clarify the potential for increasing minimum flow and for controlled flow releases for recreation, with the current dam structures or with some type of modification to those structures (e.g., new gates).***

*West Branch Below Stone Dam – Level 2 or Level 3 study*: FERC, in the Study Plan Determination discussion of the Whitewater Boating Assessment Study indicated that "a Level 2 or Level 3 study may be deemed necessary as a result of the Level 1 study findings". The approved Level 1 study did not provide sufficient information to meet the Study goal to assess "acceptable paddling flows under current and proposed Project operations" on this river reach, with only two interviews conducted, and otherwise relying on existing video documentation, with little correlation between the minimum boatable flow data derived from each source. We therefore believe a justification has been demonstrated of the need to conduct a Level 2 or 3 study on this reach. The flows to be evaluated should consider both the Level 1 Whitewater Study information and the results of the Instream Flow and Habitat Assessment of West Branch Downstream of Stone Dam Study. The additional information to be provided through a Level 2 or Level 3 Whitewater Study would help inform pending analysis of alternative minimum flows for this reach. ***We therefore request a Level 2 or Level 3 Whitewater study be planned with the cooperation of American Whitewater and other paddling interests, with flows provided in an appropriate range for land-based or water-based evaluation by paddlers, to further investigate potential recreation flows.***

Aesthetics Study

*Upper Gorge:* The Aesthetics Study Plan acknowledges the scenic value of the gorge, as viewed from the Upper Gorge Trail. Indeed, the gorge is among the most dramatic in the state, and the Upper Gorge Trail provides the best opportunity for the public to view it (particularly for non-



boaters and non-anglers who do not venture into the gorge itself). However, the Aesthetics Study KOP ratings for this site (which combined Ripogenus Dam and the Upper Gorge Trail) focused on views of the dam and of the lake. (Notably, the Recreation Study did not seem to adequately capture use of the gorge trail, and user's experiences on the trail, with only nine users surveyed and at the ISR meeting it was stated that most of those observed at the site did not leave the dam or dam parking area.) As such, the goal of the Aesthetic Study to "…develop baseline documentation of the scenic views…from KOPs where the Project area is frequently viewed by the public..." has not been fully accomplished.

Furthermore, an important variable affecting the aesthetic value of the gorge is the level of river flows. But the aesthetic benefit of various flows in the gorge was not effectively addressed in either the Recreation Study or the Aesthetics Study. We, therefore, believe that the approved Aesthetic Study methodology does not fully meet the goals and objectives of the approved study for this site.

While we do not now propose that an Aesthetic Flow Study be conducted, as at other dams currently undergoing relicensing in Maine, we believe existing and potential recreational flows and habitat flows in the gorge under the future new license have aesthetic value and these should be evaluated. ***We therefore request that the licensee undertake new information gathering, with an aesthetic evaluation of the views of the gorge from the dam and the gorge trail under various spill or scheduled whitewater flows. This could be accomplished using the existing KOP evaluation form.***

Thank you for the opportunity to submit these comments. Please feel free to contact me at (207) 287-2163 or via email at Jim.Vogel@maine.gov if you have any questions.

Sincerely,

**Subject: Maine DMR comments on Ripogenus Hydroelectric Project (FERC No. 2572-133) and Penobscot Mills Hydroelectric Project (FERC No. 2458-247) Upstream and Downstream American Eel Initial Study Report**

Dear Secretary Bose:

On April 24, 2023, Great Lakes Hydro America, LLC (Licensee) submitted their Initial Study Report for the Ripogenus Hydroelectric Project (FERC No. 2572-133) and the Penobscot Mills Hydroelectric Project (FERC No. 2458-247) on the West Branch of the Penobscot River in Maine. Enclosed are the Maine Department of Marine Resources (MDMR) comments focusing on the Upstream and Downstream American Eel portion of the study report.

Furthermore, on June 28th, the Maine Council of Trout Unlimited sent their draft comments on the Initial Study Report to MDMR, which include a request for a ramping study. MDMR supports this request for a ramping study. Analysis of the Licensee's hourly flow data by the National Marine Fisheries Service, included in TU's comments, clearly demonstrates that operations have changed since the previous relicensing and that peaking is occurring. Peaking operations can negatively impact both resident and migratory fish species through stranding and direct mortality, and through declines in the macroinvertebrate community. Thus, MDMR urges the Commission to approve the Maine Council of Trout Unlimited request for a ramping study.

MDMR looks forward to further collaboration with the Licensee on diadromous fish passage at the Ripogenus and Penobscot Mills projects. Please contact Casey Clark (casey.clark@maine.gov; 207-350-9791) or Lars Hammer (lars.hammer@maine.gov; 207-557-1564) if you have any questions.

Sincerely,

Sean Ledwin

**MDMR Comments on US American Eel Passage Study Report**

Page 4: Methodology "Survey techniques included repeated visual, nighttime observations from safely accessible locations along Project structures at the dam; these techniques are frequently used to identify whether eels are arriving at a dam and where they attempt to pass upstream. Survey areas at the East Millinocket Development included the dam face, spill gates, wooden flashboard section of the spillway, and concrete piers, which were accessed from a walkway across the top of the dam (Figure 1). Surveys were also completed along the river right abutment of the dam (Figure 1). Researchers used binoculars and spotlights with infrared lighting to observe eels during non-spill conditions.

General requests from MDMR for inclusion in the study methods:

- Please include a specific description of the lighting used during the surveys.
- Please include a depiction of how far across the spillway the walkway extends. Please also include a depiction of how far into the river the river right access in Figure 1 extends.
- Please include a description of how far from the project features observers were during the surveys. Please also include a description of how far observers were from the downstream edge of the skirt of spillway.
- Were observers able to see the area between the powerhouse and the spillway that is shown in photo 1? Specifically, the powerhouse side of that area?
- Did observers survey the river left side of the powerhouse?

Page 4: "Surveys were planned for the last week in May, first week in June, and last two weeks of October; however, American eels could not be observed due to the amount of water spilling over the dam during those times."

Page 5: "An initial survey was planned for the last week in May of 2022, shortly after the SPD was issued; however, that field effort was cancelled due to spill of seasonal high flows occurring at the dam, which prevented safe and effective sampling immediately downstream of the East Millinocket dam."

MDMR Comment: Note that nighttime surveys and electrofishing surveys were not completed in May due to high water. The former was also not completed in the last two weeks of October.

Page 6: "The traps were deployed on June 28 for 48 to 96 hours per week until July 28."

MDMR Comment: The short period of deployment of these traps each week and short duration through the season likely limited their effectiveness severely.

Page 7: "Each trap consisted of a covered eel ramp with eel substrates, a collection trap, batteries, solar panels, and water pumps (Photo 1 and Photo 2). Traps were placed on the river left side of the dam near where eels had been seen congregating during nighttime surveys performed in June."

MDMR Comment:

- The study plan does not provide details on the eel traps that were used. Please describe the substrate, ramp angle and length, and other specifics of the traps. Remember the basis of a scientific study is that is must be repeatable. Please include specifications so these traps could be recreated to repeat the study.

OFFICES AT 32 BLOSSOM LANE, MARQUARDT BUILDING, AUGUSTA, MAINE
http://www.Maine.gov/dmr
PHONE: (207) 624-6550 FAX: (207) 624-6024

- MDMR was not consulted about the location of the traps. Had we been consulted about the location, we would have recommended placement of an additional trap on river right and below areas of seepage below the dam. In addition, we were not consulted about the request to stop the eel trapping effort.

Page 16: "Nearly all eels were seen at the top of the dam, attempting to pass under a closed steel gate at a former log sluice adjacent to the powerhouse (Photo 5, Photo 6, and Photo 7); there was a small amount of water consistently leaking from under the gate. A few eels were also observed intermittently below the flashboards on the dam face early in the migration season."

MDMR Comment: As you note, eels were likely attracted to "a small amount of water consistently leaking from under the gate." Please describe the conditions of leakage, spill, etc. at all project facilities throughout the survey period. Please also describe how these conditions were consistent with or differed from operations. In addition, please provide a description of how leakage under the gate compared to leakage over the spillway or other project features. Finally, with normal leakage passing the spillway, what is the depth and velocity of water on the skirt of the spillway? Is the depth and velocity consistent?

**MDMR Comments on Downstream American Eel Passage Study Report**

Page 2: "Calculate approach velocities at the intake for each powerhouse at the Ripogenus and Penobscot Mills Projects over a probabilistic range of inflow values representative of the expected out-migration window of September-October for comparison to American eel swim speeds."

MDMR Comment: American eels initiate out-migration under a wide range of conditions and across multiple seasons. Thus, individuals are likely migrating outside of the September-October window as well.

Page 5: "The TBSA tool was used to evaluate survival probabilities for a theoretical stock of eels characterized by a user-defined, normally distributed range of body lengths."

MDMR Comment: Please provide information to support the use of a normal distribution rather than a different distribution.

Page 35: "A total of 543 eels were netted following turbine passage at the Haandrk Power Station, River Vecht in the Netherlands. Eels at this location passed through a Kaplan turbine with a 5.2-foot runner diameter, 4 blades, and a rotational speed of 150 rpm. Survival of eels at this location (average size = 460 mm) was estimated at 76 percent.

MDMR Comment: Does this study report a range of sizes or just the mean?

Page 61: "These field-based observations are in contrast to the desktop estimated values obtained from the TBSA model assembled for the Ripogenus Project and suggest blade strike may not occur at the elevated rates predicted for this site."

MDMR Comment: It is unclear if these field-based observations can be used to make comparisons between the desktop TBSA estimates and those for Station No. 1 of the Turners Falls project. The study

does not seem to compare discharge experienced during tagging to normal project operations and flows experienced during the entirety of the eel passage season. The researchers also used a latent survival of 48 hours not 96 hours as represented in Table 11.

Page 75: “Based on the assumptions contained herein, for a median outflow condition passage success for female-sized eels was estimated at 6.4 percent for individuals originating upstream of the Ripogenus Project, 10.1 percent for those originating between the Ripogenus and North Twin developments, 18.9 percent for those originating between the North Twin and Millinocket developments, 30.4 percent for those originating between the Millinocket and Dolby developments, and 62.1 percent for those originating between the Dolby and East Millinocket developments.”

MDMR Comment: The downstream eel passage route and survival assessment demonstrated low survival across all projects (particularly in the TBSA model, which was not used to inform cumulative passage success through all projects). Please reiterate here that the TBSA model resulted in estimates of zero or near zero percent survival from all potential outmigration sources. We look forward to working with GLHA to identify protective measures to increase cumulative survival at these projects.

Maine Professional Rafting Outfitters

July 6, 2023

Ms. Kimberly D. Bose
Federal Energy Regulatory Commission
888 First Street, N.E.
Washington, D.C. 20426

**Re:** Comments on the Initial Study Plan for the Re-licensure of the Ripogenus Project (P-2572) and the Penobscot Mills Project (P-2458), and Request for Further Study by Maine Professional Rafting Outfitters

Dear Secretary Bose:

The Maine Professional Rafting Outfitters ("MEPRO") hereby submits these comments on the Initial Study Plan ("ISP") for the Ripogenus Project (P-2572) and the Penobscot Mills Project (P-2458) (each a "Project" and together, the "Projects") and further requests an amended or supplemental study to address opportunities to enhance access to key areas of the river for recreational and whitewater boating purposes.

As an initial matter, MEPRO thanks FERC for the opportunity to provide comments on the ISP and looks forward to working collaboratively with the dam owners, lakefront property owners, and other interested parties to ensure that the water bodies impacted by the Projects are maintained and made accessible for commercial and non-commercial recreation activities, the lifeblood of the economy in northern Maine.

## Background

MEPRO is an unincorporated association of whitewater rafting companies that operate in and around the Penobscot River and all other major rivers in Maine. MEPRO participated in the Projects' last FERC licensing proceeding and is a party to a 1993 settlement agreement with Great Northern Paper, Inc. dated September 2, 1993 (the "Settlement Agreement") that resolved issues raised in that licensing process related to the rafting community. In that Agreement, MEPRO and the Projects' previous owners committed to "working together in partnership to assure a healthy future for their industries and an enlightened and balanced stewardship of the river resource that supports their industries." MEPRO remains committed to that sentiment. Collaboration among interested parties is perhaps more important now than it was thirty years ago, and we all share an interest in preserving the economic, recreational, environmental, and commercial vitality of these important natural resources. MEPRO members have been and continue to be committed to a thoughtful, respectful process that maximizes use and appreciation of impacted water bodies by all stakeholders.

## Purpose of Comments and Request

MEPRO's comments and request for an amended study are intended to ensure that its members' commercial operations on the impacted river segments are maintained and enhanced to the maximum degree possible in the context of this re-licensing process. MEPRO believes that each re-licensing process presents an opportunity for various stakeholders to come together and coordinate an appropriate balance of their diverse interests with the continued operation of a hydro-electric facility.

In addition to the comments provided, which primarily relate to preserving the terms of the Settlement Agreement, this document is also a request for an amended Whitewater Study to address one of its stated objectives, evaluating the "need for additional whitewater boating opportunities in the Project region."[1] In the alternative, we request a supplemental Access Study to explore ways to increase and enhance access for commercial and non-commercial use of the West Branch of the Penobscot River and Millinocket Stream within the Project area.

## Comments

MEPRO very much appreciates that Brookfield included whitewater boating and recreational elements in its ISP and its members found those portions of the ISP to be helpful and instructive in reporting on the current conditions in those areas.

### I. Whitewater Boating Assessment Study ("Whitewater Study")

#### A. Enhancement of Use

The Whitewater Study identifies a desire to evaluate both whitewater boating conditions and opportunities.[2] MEPRO is pleased to see that whitewater rafting conditions are perceived as positive, and that users are enjoying the river. MEPRO also appreciates that the Whitewater Study identifies a large number of opportunities in the area.[3] MEPRO observes, however, that the identified opportunities do not seem to be translating to increased use, as illustrated in Figure 6.1. That disconnect is part of the basis of the request for an amended study contained herein. While the use has decreased somewhat, MEPRO members are still participating in and contributing to an important sector of Maine's economy. This sector warrants protection and enhancement wherever possible. MEPRO members bring tourists to the area, employ staff, and are an integral component of the hospitality industry in Maine.

#### B. Flow Ranges and Timing

[1] Whitewater Boating Assessment Study at Q-2.
[2] *Id*. at Q-1.
[3] *Id*. at Q-28 - Q-30.

MEPRO recognizes that minimum flows vary across different stretches of the river, and that ideal minimum and maximum flows vary based on the type of craft used to navigate the river. In the stretch beneath McKay Station, MEPRO members have found that a minimum flow of 2200 and a maximum flow of 3200 CFS is optimal for commercial whitewater rafting. Per the Settlement Agreement, minimum flows that were generally able to meet these needs have been maintained during the period running from May 1 through October 1 each year, during the hours of 8:30 A.M. to 5:00 P.M. During the established whitewater rafting season, the lower limit on releases should be 1,800 CFS at McKay station. Under extreme conditions (drought), the lower limit would be 1,600 CFS from 5:00 P.M. to 5:00 A.M. From 5:00 A.M. to 5:00 P.M. the minimum flow at McKay station would revert to 1,800 CFS. Under normal conditions, the preferred flow will be 2,400 CFS with an upper limit of 3,200 CFS.

MEPRO respectfully requests that this re-licensing process maintain those flows provided for in the Settlement Agreement.

From a timing perspective, however, MEPRO would like an opportunity to discuss the possibility that, during rafting season, the flows begin at 5:00 A.M., rather than 8:30 A.M. An earlier start would cause flows to fill up the dead waters and enable commercial trips to run the entire river. Having the opportunity to run the entire river would be a significant enhancement to the quality of the boating experience, allow MEPRO members to attract more users to the area, and should be achievable with only a minor operational adjustment. MEPRO looks forward to discussing this further, and learning more about the opportunities and impacts such an adjustment could create.

## II. Access-Related Issues

Upon review of the ISP materials, MEPRO believes that there is a gap in information relating to enhancing access to the river. MEPRO expected to see a more robust exploration of this issue in the Whitewater Study. MEPRO believes that access issues can be appropriately addressed in either in an amended Whitewater Study or in a supplemental study specific to access.

No matter what vessel is used, MEPRO members suggest that the area along the McKay Station to Debsconeag Deadwater section of the West Branch is an appropriate starting point for exploring enhanced access. Particular attention might be paid to the following specific locations:

1. Little Eddy – Access at Little Eddy (river right) to enhance an important put-in when the McKay station launch is not available due to maintenance or safety issues.
2. Big Eddy – Access immediately below Big Eddy (river right).
3. Big Amberjack - Access above Big Amberjack (river right) and below Big Amberjack (river right).
4. Nesowadnehunk Dead water - Access at the top of Nesowadnehunk Dead water (river

right).

5. Nesowadnehunk Falls - Access immediately below Nesowadnehunk Falls (river right) would allow trips to begin or end at this location.
6. Abol Bridge - Access just below Abol Bridge (river left).
7. Debsconeag Falls - Access at Debsconeag Falls. Improving access to Debsconeag Falls would add a significant section of Class V whitewater and create the potential for more robust two day trips, seven days a week all season long with no change in flows or operational models.

All the above recommended access points (ingress and egress) are important in offering a diverse variety of trips and improving the quality of existing whitewater rafting routes. Customers consistently expect more whitewater and better routes for boating experiences; improving access can help the industry better meet, and exceed, our customers' expectations. Increased opportunities for access and egress also advance safety concerns by making evacuation from the river easier.

The suggestion of either an Amended Whitewater Study or a Supplemental Access Study are expressions in the alternative – MEPRO does not suggest that both should be undertaken.

### A. Amended Whitewater Study

MEPRO suggests that amending the Whitewater Study may be the most logical place to enhance the evaluation of access opportunities, as it appears to fit squarely within one of the key objectives of that study as originally contemplated – that of evaluating the "need for additional whitewater boating opportunities in the Project region."[4] As noted in the Whitewater Study at Appendix Q-22, there has been a downward trend in commercial whitewater use of this area of the river, beginning in approximately 2005. This downward trend was exacerbated by the impact of the COVID-19 pandemic, resulting in 2020 having the lowest use rates since 2005. Even with that decline, there are between 8,000 and 10,000 rafters per season, which contribute meaningfully to Maine's economy.

MEPRO respectfully observes that the size of the industry, and the recent downward trend, provide a strong basis for exploring additional whitewater boating opportunities in order to attract more and different users. Stabilizing and stimulating the whitewater industry is of critical importance to MEPRO members and the operation of the dam provides opportunities for such enhancement, which may include increasing flows at different times of day or season.

To be clear, however, MEPRO is not currently proposing that enhanced opportunities would necessarily come from additional releases, or other activities that would stress the operation of

[4] *Id*. at Q-2.

the facility or change water levels for shoreland landowners. Instead, MEPRO would like to see Brookfield satisfy the goals of the Whitewater Study and Recreation Study Report by exploring those areas of the river that currently have sufficient flow to support rafting activities, but have challenges associated with access. MEPRO proposes that the amended study focus on whether there is a way to resolve such access issues in a manner that enhances the experience of the recreational users served by MEPRO, and by extension MEPRO's commercial operations, without negatively impacting the experience of landowners or the efficient operation of the dam for its core purpose, the generation of electricity. MEPRO believes that this might allow the Projects to enhance the industry's recovery from loss of business over time (more acutely during the Pandemic) and support the industry's efforts to become more diverse and resilient without additional impacts to other users of the resource, including landowners.

### B. Supplemental Access Study

In the alternative, MEPRO respectfully requests a supplemental Access Study to explore ways to improve and expand access to the West Branch of the Penobscot River and Millinocket Stream within the project Areas. Commercial and non-commercial recreation activities are a critical economic engine in this region. Whitewater recreation activities bring in tourism dollars from all across the country and the industry provides numerous jobs, not just for whitewater boating companies and staff, but also for ancillary services in the food and beverage, lodging, and transportation sectors. Many businesses in the region rely on the stream of rafting visitors as a primary source of income. The Projects should be required to investigate ways to preserve, but also enhance and expand, this critically important industry.

Historic markers or informational kiosks at strategic locations, like the Ripogenus Dam and the staging area at McKay Station, may provide a low-cost way to enhance the visitor experience. Markers and kiosks would also help preserve and promote the history of the Great Northern Paper Mill and the logging industry in the Project area.

Decades have passed since these Projects were last issued licenses, and FERC should take this opportunity to require Project owners to explore additional ways to increase recreational and commercial access to and use of the river resources within the Project areas. MEPRO members are interested to learn about creative solutions that could expand river access and egress to new areas, thus providing more opportunities for recreational and commercial activity in the region without negatively impacting other users or the Projects' hydropower generation activities.

A supplemental Access Study would augment other studies in the ISP, including the Recreation Study Report, whose objectives include a review of access to boat launches as part of its "facility inventory and condition assessment for the FERC-approved Project recreation sites, a recreation use assessment, a user survey, and an assessment of select impoundment boat launches."[5]

[5] Recreation Study Report at P-1.

## III. Socioeconomic Study

Finally, we take this opportunity to amplify our prior discontent with the exclusion of the Socioeconomic Study proposed by the Penobscot Indian Nation. The Licensee acknowledges that there have been significant socioeconomic changes in the region in the past 25 years, due in large part to the closure of the Great Northern Mill. The mill closure, in particular, and a decline in the availability of job opportunities in general, have had a devastating impact on the socioeconomic climate in northern Maine. The region is more dependent on the commercial recreation and tourism industries than ever, and the importance of preserving and expanding opportunities for these industries to grow should be prioritized throughout this process.

While the Licensee asserts that whitewater boating locally and nationally is in decline, and our experience has been that the number of rafting trips per year in the region has been volatile over the past few years, due in large part to the Covid-19 pandemic, recently there has been renewed interest in outdoor activities and exploration of our natural environment. The industry is still running between 7,000-10,000 rafting trips per year on the West Branch of the Penobscot River, and every effort should be made to preserve and enhance this important industry through this FERC relicensing process.

## Conclusion

MEPRO thanks FERC for the opportunity to provide comments in this proceeding. We look forward to working with all stakeholders to ensure that the relicensing of the Projects maintain and enhance the expectation that Project owners partner with other river users as responsible stewards, maximizing the opportunities for commercial and noncommercial use of and access to this important natural resource.

July 9, 2023

**Via Electronic Filing**

Dear Secretary Bose:

**RE: Complaints and Comments in Response to the Environmentally Diasterous McKay Station Outage and the failure of Emergency Outage Measures of July 7, 2023 (FERC No. 2572-133)**

ON July 7, 2023 at 7 PM the Brookfield Website listed a McKay Station (McKay) flow of 100 cfs (see photo below). At 9:47 this website continued to list the McKay flow as being 100 cfs and campers reported the flow remained low at 11 PM. The extent and exact reason for this catastrophic outage is unknown at this time.

While this outage may have been a result of conditions beyond the licensee's control, the response was surely within the Licensee's control. It is ridiculous for a multi-million dollar corporation not to have in place a back–up generator with an automatic switch capable of opening a gate at Ripogenus Dam "not if but when" there are problems at McKay. Seemingly every small business and many home owners in rural Maine have back-up generation fueled by propane which kicks instantaneously on when the power-line flow kicks off. These cost less than $10,000 installed for 20Kw capacity. I have no idea how many kW is needed to lift a gate a Rip Dam – 2x, 3x, maybe 10x. That would be $100,000, a small, in fact teeny price to mitigate the cost to the environment caused by draining a river. FERC must act.

Any McKay outage has major impacts of fish and aquatic communities. However, this extreme (100 cfs), extended (four plus hours) event was particularly devastating to recently emerged alvin (salmon recently exiting the redd) as well as the biologically active aquatic insect communities. Poor turbine design and maintenance as well the Licensee's gate opening response is not acceptable and FERC should act to prevent prolonged McKay outage events in the future.

Historically Great Northern Paper housed a "dam tender" at Ripogenus Dam. The operator's responsibilities included checking water levels and making gate changes at upstream impoundments. Typically, the dam tender completed his duties by early afternoon and was available for emergency Ripogenus Dam gate changes. As a cost saving measure, the Dam Tender position was abounded circa 2000 and a layer of environmental protection lost.

The outage of July 7 demonstrates two shortcoming of the Licensee's emergency flow management at McKay Station. The Licensee failed to maintain the "trip" mechanism that allows 500 cfs of flow though McKay turbines. Then to further exasperate the situation, the response time of the traveling crew was at least four hours. This long delay was also avoidable.

The October 2022 Outage Study (Appendix F, Initial Study Report) provided impacts of a 500 cfs flow. At a flow of 100 cfs, the July 7, 2023 event is much more extreme. The timing of this diasterous outage could not be worse as it occurred during the peak fish and aquatic growing season and a prime angling period and it occurred during daylight hours. Recently emerged alvin (larval salmon) are extremely vulnerable to rapid flow change and the initial dewatering and subsequent flooding of the riverbed. The Holbrook Spawning, Incubation, and Nursery Channel (Article 406) would have been completely dewatered during this four-hour plus event. Essentially the entire West Branch 2023 salmon year class was eliminated. Salmon parr, typically age I fish, are more mobile, it is likely a few ages I and older parr survived.

Aquatic insects are immobile and cannot escape or survive a four-hour period of 100 cfs flow. Beginning in July the adult and sub-adult salmon population become concentrated in the upper 1 ½ mile river reach below McKay Station. There are few, if any smelt, exiting McKay Station. The sub-adult and adult salmon surviving this event will be left without their normal summer maintenance diet of aquatic insects. Growth of surviving fish will diminish as will the survival of undernourished fish.

While anglers are not a direct component of environment disasters, fishing is a traditional part of McKay operations. The 1996 EIS referred to West Branch fishing downstream of McKay Station as high quality. Anglers will not continue to fish locations where there are no or few fish. The July 7, 2023 outage impact on angling remains to be determined. The loss of fishing opportunity and concurrent camping activities at local lodges, camps, and campgrounds as well as the Millinocket area economy are factors yet to be determined.

FERC has the ability to prevent and/or minimize future catastrophic flow interruptions caused by outages. Long-term and short-term mitigation measures are needed. Initially, FERC should order that a McKay Dam Tender position be created and staffed during the aquatic growing season, housing is readily available. Secondly, McKay Station emergency flow mechanism should be "reengineered" and maintained. Thirdly, during the ongoing licensing, the appropriate emergency outage

flow should be determined as well as methods of delivering that flow to the river. Long term mitigation is needed to rebuild salmon stocks, notable the loss of 2023 hatchlings (alvin) and aquatic insects. This can be accomplished by requiring minimum flows of 2200 cfs accompanied by requiring the Licensee to follow a Ripogenus Impoundment storage curve that guarantees storage will be available to meet the year-long minimum flow goal

The Preliminary Application Document and Notice of Intent boasts of Protection, Mitigation and Enhancement (PME) measures provided by project operations. The July 7, 2023 outage event eliminated many of the PME measures, impacts on salmonid populations will likely last for several years. FERC should hold the Licensee accountable to standards they tout so often.

I urge FERC to act and provide fish and aquatic communities of the West Branch below McKay Station with protection now and in the future, against environmentally catastrophic outages such as those witnessed and recorded on July 7, 2023.

Thank you for the opportunity to comment and make suggestions.

The Big Eddy on July 7, 2023 at 7 PM

Jeffrey Scott Murphy, Orono, ME.
National Marine Fisheries Service's Greater Atlantic Regional Fisheries Office supports the ramping study requested by the Maine Council of Trout Unlimited (TU) on July 5, 2023. Analysis of the Licensee's hourly flow data by us (which were included TU's comments) clearly demonstrates that operations have changed since the previous relicensing and that peaking is occurring. Peaking operations can negatively impact both resident and migratory fish species through stranding and direct mortality, and through declines in the macroinvertebrate community. Thus, NMFS urges the Commission to approve TU's request for a ramping study in the West Branch of the Penobscot River downstream of McKay Station.

Kimberly D. Bose,
Secretary
Federal Energy Regulatory
Commission 888 First Street,

July 20, 2023

**Via Electronic Filing**

RE; Project No 2458-247 The Historic West of the Penobscot River Channel Below Stone Dam. Staff Comments on the Initial Study Report and Initial Study Report Meeting Summary, No 5, Instream Flow and Habitat Assessment Study (Stone Dam).

Dear Secretary Bose:

FERC Staff comments of July 6, 2023 requested studies of the Historic West Branch Channel (Channel) below Stone Dam be expanded to include "f*ishability (i.e., the potential for anglers to safely wade and fish) of the reach at the range of flows modeled (0 to 2,000 cfs)."* I concur and support Staff's request and suggest that studies or plans be expanded. I would like the study to include how anglers would 1) reach the Channel and then 2) move up and down the Channel to fish. Support for my request is explained below.

The Historic West Branch Channel is wider and features run and riffles and is very much UNLIKE Millinocket Stream. The Licensee is suggesting a duplication of the failed Article 413 plan that requires Millinocket Stream May and September stocking of "3 to the pound" adult brook trout. On numerous occasions the Licensee has failed to meet time or trout size criteria required by Article 413. Source fish will remain a problem.

As a 1996 license requirement, then Great Northen Paper (GNP) surveyed anglers fishing Millinocket Stream in the late 90's (see archival GNP files). Much of Millinocket Stream is bracketed by access roads leading to Millinocket Lake. In many cases subsequent stream access is 100-200 feet from these well-traveled roads. During the initial period (Circa 1997) of this enhancement measure GNP was able to obtain source trout from a private hatchery. Despite all the favorable conditions listed above, angler activity lasted one to two weeks.

There are no available/passable roads to the historic West Branch Channel and no trails or foot paths once the Channel is reached by vehicle or boat. In areas the stream bank is covered by boulders, several areas are steep sided. From experience, it is not easy walking up and down the 2 ½ mile reach. Both the channel configuration and river bank are very much unlike Millinocket Stream.

I urge FERC Staff to include an angler access component to the Fishability Study. Additional information should include possible vehicle routes to the site area, Stone Dam, as well trails or foot paths along both sides to the West Branch Channel. Historically Millinocket Stream was stocked in five locations, the access study report should include potential trout stocking locations and discussion of how the hatchery truck will reach these locations in the absence of passable roads.

Additionally, the availability of trout raised in private hatcheries appears to be a problem. In recent years, MeDIFW has provided Millinocket Stream trout, the size and timing of these stocking has failed to meet Article 413 requirements. Is the Licensee paying MeDIFW to stock trout? The Licensee should explain the practically and costs of meetings Brook trout stocking goals.

The Licensee is attempting to reduce future License 401 Water Quality Certificate flow requirements in the historic West Branch Channel. The initial suggestion was a “Field of Dreams” stocked brook trout proposal doomed to failure. Agencies, stakeholders, and FERC Staff need a complete record of the historic West Branch Channel study results that provides information on aquatic habitat as well as fishing and boating opportunities. Angler fishability as well as angler and vehicle access information need to be included in that record.

Thank you for the opportunity to comment and make suggestions.

TROUT UNLIMITED
MAINE COUNCIL

**Via online submission to: http://www/ferc.gov**

Subject: **Comments of Maine Council of Trout Unlimited on the Flow Excursion Report Submitted on July 21, 2023 for the Ripogenus Project, Project Number P-2572**

Dear Secretary Bose:

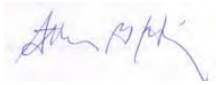
On behalf of its six chapters and over 2,000 members, Maine Council of Trout Unlimited (TU) submits these comments on the Flow Excursion Report for the Ripogenus Project (P-2572) filed for Great Lakes Hydro America, LLC by Brookfield Renewable ("Brookfield" or "Applicant") submitted on July 21, 2023. With two generators put out of commission at McKay Station, this must be considered a serious event that deserves FERC's full attention. Given the strandings and mortality documented by the Brookfield Stranding Study conducted on October 5, 2022[1] incident to the ongoing relicensing of the project that were confirmed and documented by TU volunteers,[2] consequences to the aquatic resources downstream are a serious concern to TU, its membership and Maine's public.

The outage that initiated the chain of events addressed by Brookfield's report was described by Ed Spear in his July 19, 2023 filing: "On July 7, 2023 at 7 PM the Brookfield Website listed a McKay Station (McKay) flow of 100 cfs (see photo below). At 9:47 this website continued to list the McKay flow as being 100 cfs and campers reported the flow remained low at 11 PM."[3] This filing was based on Brookfield's own data and was confirmed by observers. Rather than address this in the flow excursion report as would be expected and as Brookfield has done for trip events in the past, the report terms the event a "Whitewater Recreation Flow Excursion" in its Subject block and proceeds to describe the lesser flow excursion of 1373 cfs that occurred the following day. The report refers to the trip event of July 7 in an attached email message.

The report states that the events of July 8 were a violation of license terms and conditions but the attached email says that the events of July 7 were not. This is a determination that is the prerogative of the Commission, not the licensee - one that should be based on the best information available.

Concentrating on the whitewater recreational flow excursion that occurred on July 8, the report provides graphical generation data documenting the event. Since there is no USGS flow gage below McKay Station in the West Branch of the Penobscot, inferred flows from generation data are the best quantitative information available. The attached email concerning the July 7 event says outage flows

[1] Initial Study Report, Ripogenus Hydroelectric Project (FERC No. 2572), Penobscot Mills Hydroelectric Project (FERC No. 2458), Great Lakes Hydro America, LLC, Millinocket, Maine dated April 24, 2023, Appendix E.
[2] Maine Council of Trout Unlimited letter dated October 19, 2023, Subject: Report of Observations on Ripogenus Project Fish Stranding Study.
[3] Ed Spear Letter dated July 19, 2023, Subject: RE: Complaints and Comments in Response to the Environmentally Diasterous McKay Station Outage and the failure of Emergency Outage Measures of July 7, 2023 (FERC No. 2572-133).



occurred without providing the flow rate, duration, or graphic flow data as was provided for the July 8 flow excursion. Brookfield continues to withhold critical flow information as well as deep gate changes.

**We ask that FERC require that Brookfield submit similar generation data graphics for both July 7, 2023 and July 8, 2023 in their entirety, accompanied by a chronological narrative of the events that occurred during that timeframe.**

This is not the first time that a major malfunction has occurred at McKay Station under Brookfield ownership. A somewhat similar event occurred on June 13, 2015 that was the object of FERC scrutiny that also necessitated use of the deep gates of Ripogenus Dam to maintain flows. Brookfield reported that the problem had been corrected.[4] At the ISR Meeting held last May, Brookfield stated that the project now provided 500 cfs trip flows that exceed the 400 cfs license requirements. This calls the issue into serious question and warrants revisiting by the Commission.

TU has on multiple occasions asked for a schematic of the design of the McKay Station generation facility and reiterates that request.

Respectfully,

Stephen G. Heinz
Maine TU Council FERC Coordinator

Email copy to: Alicia Burtner, FERC Compliance

[4] Brookfield letter dated January 7, 2016, RE: Ripogenus Project 2572, Article 402 Compliance; Follow-up to June 13, 2015 Flow excursion due to McKay Station outage. FERC Document Accession #: 20160107-5108.

Kimberly D. Bose, July 28, 2023
Secretary
Federal Energy Regulatory Commission
888 First Street, NE
Washington, DC 20426

Dear Secretary Bose, Via Electronic filing

Subject: Project 2572 Response to Great Lake Hydro America filing: 20230721 Ripogenus Project P-2572; July 8, 2023 Whitewater Recreation Flow Excursion Report

On July 7, 2023 the water all but stopped flowing for 22 miles below McKay Station on the West Branch of the Penobscot River (West Branch). Brookfield's Safewaters website listed McKay Flows at 100 cfs at 7 PM. The current Licensee, Great Lakes Hydro America, is entrusted with the management of this precious public resource. Two weeks after this event, the Licensee filed a letter on July 21, 2023 that mentioned the July 7th lighting strikes but dealt with the July 8th impacts to boating that resulted from flow excursions below McKay Station on the West Branch.

The above referenced recreation flow excursion report is an attempt to obfuscate damage to fish and aquatic communities during the outage of July 7, 2023. The report dealt with a two hour impact on boaters rather than the four plus hour impact to fish and aquatic communities, ie., recently emerged landlocked salmon (salmon) and adult salmon summer food source; caddis, mayflies, and stoneflies. Photos and reports from campers along the river indicated flows remained low at 11 PM on July 7th. The impact to fish and aquatic communities will be long lasting. On the morning of July 8th a boater reported approximately 10 dead sub adult salmon in a small pool on the edge of the McKay Station. Other mortalities were likely concealed by nighttime darkness.

The Licensee's account of July 7th is rather confusing. I struggle to understand how "*all of GLHA's hydro stations on the Penobscot River tripped offline due to a lightning strike to the local utility's (Versant Power's) transmission line*." could destroy two McKay Station turbine 30 miles upstream. Bearing oil seems to be a focus of the outage. It would be helpful if a recent maintenance schedule could be provided. The Licensee fails to mention the implementation, if any, of emergency McKay turbine outflow or how that flow was provided with two disabled turbines. The Licensee has provided graphic West Branch flow details of July 8th. They should do the same for July7th beginning at 3PM.

In pleading guilty to a two hour interruption in boating flows the Licensee attempts to deflect attention away from the more environmentally disastrous, four plus hour, low flow event, that impacted the West Branch salmon fishery and aquatic communities. The Licensee's July 21, 2023 filing fails to mention the time the trip event began (an attached July 10 Email from K. Bernier states the outage began at 1759 h), when deep gates were opened, and why McKay Station energy outage flow measures appeared to fail. Rather than discuss environmental and recreational impacts, the Licensee goes into great details concerning turbine damage. Outages are an annual event. The magnitude and duration of the July 7th event is historic.

The Licensee has yet to file a July 7th outage report. The July 21, 2023 filing is a separate event and deals with <u>boating flow excursions on July 8</u> rather July 7, the day of the lighting strike(s). In addition to a July 7th outage report that includes flow over time, a second report that deals with the dewatering of the Holbrook bypass stream (article 406) needs to be filed. The loss of the 2023 (young-of-the-year) salmon age class, produced by this mitigation measure, will impact the West Branch salmon population for several years

The apparent response time of the Licensee on July 7th is inexcusable as is the failure to have auxiliary generators in the Ripogenus Dam Gate house capable of lifting a deep gate during emergency outages. Technologies such as automatic transfer switches which sense power failure in line supply and switch to back-up sources and Liquid Propane-fired back up generators are available. Beginning on June11, 2021 with the Pre-Application Document the Licensee has touted protection, mitigation, and enhancement measures (PM&E). The diasterous event of July 7th produced a trifecta of failed PM&E measures.

A complete factual accounting of flows over time and Ripogenus Dam gate changes during the July 7th outage is needed in order to assess "lighting strike" impacts. The agencies, stakeholders, and FERC need a full accounting of the events of July 7, 2023. The Licensee should make this information available in a timely manner.

The loss of West Branch flow on July 7, 2023 is an actionable event. Fish and aquatic communities were impacted. Due to low flow conditions boaters and anglers lost time on the river. The Ripogenus Impoundment, Ripogenus Dam, McKay Station and downstream West Branch make up the Licensee's Ripogenus Project. Environmental and recreational disasters are the Licensee's responsibility. The Licensee needs to be held accountable. FERC has an opportunity to prevent this going forward in the ongoing (re) licensing. In the meantime, FERC compliance staff should require fish and aquatic communities' mitigation and issue civil penalties significant enough to get the attention of the leadership of this huge multinational enterprise.

Thank you for the opportunity to comment. I urge FERC to take quick and decisive action.

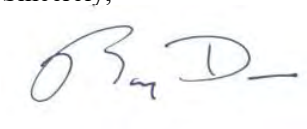
**Subject:** **Ripogenus Hydroelectric Project (FERC No. 2572-133)**
**Penobscot Mills Hydroelectric Project (FERC No. 2458-247)**
**Third Study Progress Report**

Dear Secretary Bose:

Great Lakes Hydro America, LLC (GLHA), Licensee of the Ripogenus Hydroelectric Project (FERC No. 2572) and the Penobscot Mills Hydroelectric Project (FERC No. 2458) (collectively referred to as the "Projects"), herein files with the Federal Energy Regulatory Commission ("FERC" or "Commission") the Third Study Progress Report for the relicensing of the Projects. The Projects are located on the West Branch of the Penobscot River and Millinocket Stream in Piscataquis and Penobscot counties, Maine.

The current licenses for the Projects were issued on October 22, 1996 and expire on September 30, 2026. On June 11, 2021, GLHA filed the Notices of Intent and Pre-Application Document, which initiated the formal relicensing proceeding to obtain two separate new licenses for the continued operation of the Projects through the Commission's Integrated Licensing Process (ILP). On March 23, 2022, GLHA filed a Revised Study Plan (RSP) for the Projects, and the Commission issued the Study Plan Determination (SPD) on May 13, 2022.



Pursuant to the RSP, GLHA herein submits the Third Study Progress Report for the period from May 1 through July 31, 2023 for the Projects. The enclosed table (report) provides a list of the required studies and associated status of progress, as well as any modifications to the approved methodologies.

Concurrent with this filing, GLHA is providing a copy of this letter to all parties listed in the attached distribution list. A copy of the Third Study Progress Report can be downloaded from FERC's eLibrary system at https://www.ferc.gov/docs-filing/elibrary.asp by conducting a search using the docket numbers p-2458 and/or p-2572.

# THIRD STUDY PROGRESS REPORT

| Ripogenus Hydroelectric Project (FERC No. 2572)<br>Penobscot Mills Hydroelectric Project (FERC No. 2458)<br>Third Study Progress Report<br>(May 1, 2023 through July 31, 2023) | | | |
|---|---|---|---|
| **No.** | **Study** | **Status** | **Modifications to Methodology** |
| 1a | Water Quality Study – Impoundment Lake Trophic Assessment | Study completed as required in 2022 with study results provided in the ISR. | None. |
| 1b | Water Quality Study – Downstream DO/Water Temperature Assessment | Study completed as required in 2022 with study results provided in the ISR. | • Additional water temperature data are being collected at three monitoring sites in the West Branch downstream of Stone Dam in June and July 2023 based on comments from MDIFW during the ISR Meeting.<br>• Data collected in 2023 will be provided in the USR. |
| 1c | Water Quality – Benthic Macroinvertebrate Assessment | Study completed as required in 2022 with study results provided in the ISR. | • Additional macroinvertebrate data is being collected at two locations in the West Branch downstream of Stone Dam.<br>• Data collected in 2023 will be provided in the USR. |
| 1d | Water Quality – Impoundment Aquatic Habitat Assessment | Study completed as required in 2022 with study results provided in the ISR. | None. |
| 1e | Water Quality – Riverine Aquatic Habitat Assessment | Study completed as required in 2022 with study results provided in the ISR. | None. |
| 2 | Instream Flow and Habitat Assessment of West Branch below Stone Dam | Study completed as required in 2022 with study results provided in the ISR. | None. |
| 3 | Fish Assemblage Survey Study | Study completed as required in 2022 with study results provided in the ISR. | None. |

| Ripogenus Hydroelectric Project (FERC No. 2572)<br>Penobscot Mills Hydroelectric Project (FERC No. 2458)<br>Third Study Progress Report<br>(May 1, 2023 through July 31, 2023) | | | |
|---|---|---|---|
| **No.** | **Study** | **Status** | **Modifications to Methodology** |
| 4 | Fish Stranding Study | Study completed as required in 2022 with study results provided in the ISR. | None. |
| 5 | North Twin Impoundment Tributary Access Survey | Pursuant to the RSP and SPD:<br>• Based on the consultation with MDIFW, tributary surveys were performed in mid-July 2022, but the fall 2022 survey could not be performed due to wet weather and high impoundment elevations.<br>• The fall tributary survey is anticipated to be performed in October 2023, pending suitable field conditions. | None. |
| 6 | Upstream American Eel Passage Assessment Study | Study completed as required in 2022 with study results provided in the ISR. | • Based on comments received at the ISR meeting, in consultation with USFWS, MDMR, MDIFW, and PIN, GLHA has initiated nighttime eel observations and electrofishing surveys at the Dolby, Millinocket (Stone Dam), North Twin, and Millinocket Lake Storage Developments. However, heavy precipitation experienced in June and July 2023 have resulted in high flows in the rivers and spill conditions at the dams, limiting the ability to perform the nighttime eel observations and electrofishing so far, this season. Pending reasonable flow conditions, efforts will be made to continue nighttime eel observations and electrofishing in August and September.<br>• Data collected in 2023 will be provided in the USR. |
| 7 | Desktop Downstream Eel Passage Route and Survival Study | Study completed as required in 2022 with study results provided in the ISR. | None. |

| Ripogenus Hydroelectric Project (FERC No. 2572)<br>Penobscot Mills Hydroelectric Project (FERC No. 2458)<br>Third Study Progress Report<br>(May 1, 2023 through July 31, 2023) | | | |
|---|---|---|---|
| **No.** | **Study** | **Status** | **Modifications to Methodology** |
| 8 | Recreation Study | Portions of the study were completed in 2022 with study results provided in the ISR.<br>• Because of atypical conditions at three sites in 2022, GLHA is collecting additional recreation user spot/calibration counts at the two Dolby Development recreation sites and the Green Bridge Boat Launch.<br>• Data collected in 2023 will be provided in the USR. | • Based on comments received at the ISR meeting, GLHA has redeployed the recreation user survey boxes and QR codes at most of the FERC-approved Project recreation sites throughout the Projects to collect additional survey data in 2023 and early 2024.<br>• GLHA plans to convene a recreation and access focus group to obtain additional site-specific recreation and informal access information and concerns from interested stakeholders.<br>• Data collected in 2023 will be provided in the USR. |
| 9 | Whitewater Boating Assessment Study | Study completed as required in 2022 with study results provided in the ISR. | None. |
| 10 | Aesthetic Study | Portions of the study were completed in 2022 with study results provided in the ISR.<br>• GLHA plans to coordinate an aesthetic focus group to obtain additional site-specific information and concerns regarding aesthetics from interested stakeholders.<br>• Data collected in 2023 will be provided in the USR. | None. |
| 11 | Historic Architectural Survey | Study completed as required in 2022 with study results provided in the ISR.<br>• GLHA is in the process of reviewing and addressing comments provided by the Maine Historic Preservation Commission and will provide updated information, as appropriate, in the USR. | None. |
| 12 | Historical Operations Data Assessment Study | Study completed as required in 2022 with study results provided in the ISR. | None. |

| Ripogenus Hydroelectric Project (FERC No. 2572)<br>Penobscot Mills Hydroelectric Project (FERC No. 2458)<br>Third Study Progress Report<br>(May 1, 2023 through July 31, 2023) | | | |
|---|---|---|---|
| **No.** | **Study** | **Status** | **Modifications to Methodology** |
| 13 | Operations Model Study | Study completed as required in 2022 with study results provided in the ISR.<br>• Based on comments received at the ISR meeting, GLHA is in the process of coordinating an Operations Model Study Technical Conference for interested stakeholders to further discuss the model development, model outputs, and how the model will be utilized during the relicensing proceeding.<br>• GLHA anticipates convening the technical conference in fall 2023.<br>• Subsequent to the technical conference, GLHA will provide stakeholders with a 60-day period for which to provide comments on the operations model and/or submit alternative operating scenarios to be evaluated by the model.<br>• Information presented at the technical conference, stakeholder comments, and the results of the model runs for the requested alternative operating scenarios will be provided in the USR. | None. |

Henry Mitchell, Bowdoinham, ME.
Brookfield Power has shown itself to be a poor corporate citizen, as evidenced by their poor management of the resource and disregard for the environment and the people who recreate and make a living on the West Branch of the Penobscot River.

The July 5 dewatering of the river and its decimation of a year-class of fish due to their poor maintenance, unwillingness o have a dam-keeper on site is just the most recent insult to the river, and to the people of Maine who own its waters.

Cumulatively I have spent more than a year of my life, going back to the late 70s and usually spend 2-3 weeks a year at the Big Eddy campground.

Only since Brookfield took over Ripogenus Dam that I've had to move my campsite or cut my vacation short due to their inept water management. This has happened to me twice, most recently this June. Knowing that the lakes were all full they were still only releasing 3000 cfs from Rip Dam. Then when we got torrential rains there was no buffer. We were told the water was coming up to 5000 cfs and we should move our tents. The next morning we were told it would be coming up to 9000 cfs, completely flooding our campsite as well as making the river unfishable, un-paddleable and unraftable. Another vacation cut short, another uncompensated financial blow to campgrounds, fishing guides and rafting companies.

Brookfield has shown they are not worthy of a license, I urge you not to renew it.

Respectfully, Henry Mitchell, Bowdoinham ME.

Brookfield
Renewable U.S.

August 7, 2023

***Via eFiling***

Kimberly D. Bose, Secretary
Federal Energy Regulatory Commission
888 First Street, NE
Washington, DC 20426

**Subject:** **Ripogenus Hydroelectric Project (FERC No. 2572-133)**
**Penobscot Mills Hydroelectric Project (FERC No. 2458-247)**
**Response to Comments on the Initial Study Report and Requests for New or Amended Studies**

Dear Secretary Bose:

Great Lakes Hydro America, LLC (GLHA), the Licensee of the Ripogenus Hydroelectric Project (No. 2572) and the Penobscot Mills Hydroelectric Project (No. 2458) (collectively referred to as the "Projects"), herein files with the Federal Energy Regulatory Commission (FERC) responses to comments on the Initial Study Report (ISR) and requests for new or amended studies for the Projects. The Projects are located on the West Branch of the Penobscot River and Millinocket Stream in Piscataquis and Penobscot counties, Maine.

On June 11, 2021, GLHA filed the Notices of Intent and a Pre-Application Document (PAD), which initiated the formal relicensing proceeding to obtain two separate new licenses for the continued operation of the Projects through FERC's Integrated Licensing Process (ILP). On March 23, 2022, GLHA filed the Revised Study Plan (RSP) and on May 13, 2022, FERC issued the Study Plan Determination (SPD).

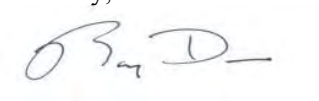
Pursuant to the RSP, and as modified and approved by FERC's SPD, GLHA performed study activities in 2022 and early 2023. Pursuant to 18 CFR §5.15(c), on April 22, 2023, GLHA filed the ISR describing the overall progress in implementing the study plan, presenting the available study results, and describing variances from the approved plan. Subsequent to filing of the ISR, GLHA held the ISR Meeting with FERC staff and other relicensing participants on May 2, 3, and 4, 2023, in Millinocket, Maine, and filed the ISR Meeting Summary on May 22, 2023.

On May 23, 2023, the National Marine Fisheries Serivce requested an extension of time to file comments on the ISR and requests for new or amended studies. Via order dated June 6, 2023, FERC granted an extension of time, until July 6, 2023, to file comments on the ISR and requests for new or amended studies. FERC's June 6, 2023 order also indicated that GLHA's responses to comments and study requests are due by August 5, 2023[1], and FERC's Study Plan Modification Determination will be issued by September 4, 2023.

[1] August 5, 2023 is a Saturday and, therefore, consistent with 18 CFR §385.2007, GLHA's responses to comments and study requests are due by Monday, August 7, 2023.

**GREAT LAKES HYDRO AMERICA, LLC**
1024 Central Street, Millinocket, ME 04462
T +1 207.723.4341 F +1 207.723.4597 brookfieldrenewableUS.com

Comments on the ISR and/or requests for new or amended studies were timely filed by the following stakeholders, copies of which are provided as an attachment to this letter:



- Federal Energy Regulatory Commission
- National Marine Fisheries Service
- Maine Department of Agriculture, Conservation & Forestry, Bureau of Parks and Lands
- Maine Department of Inland Fisheries & Wildlife
- Maine Department of Marine Resources
- Maine Professional Rafting Outfitters
- Caribou and Chesuncook Lake Camp Owners Association
- Chesuncook Dam Camp Owners Association
- American Whitewater
- Appalacian Mountain Club
- Maine Council of Trout Unlimited
- Edward Spear
- Christopher Howe

GLHA has reviewed the comments on the ISR and requests for new or amended studies as filed with FERC and herein provides responses to these comments and requests.

Concurrent with this filing, GLHA is providing a copy of this letter to all parties listed in the attached distribution list. Parties can download an electronic copy of this filing from FERC's eLibrary system at https://www.ferc.gov/ferc-online/elibrary by conducting a search using the docket numbers P-2458 and/or P-2572.

If you have any questions regarding this filing, please contact me by phone at (207) 775-5605 or by email at randy.dorman@brookfieldrenewable.com.

Sincerely,

Randall Dorman, Licensing Manager
Brookfield Renewable

Kimberly D. Bose, August 10, 2023
Secretary
Federal Energy Regulatory Commission
888 First Street, NE
Washington, DC 20426

Dear Secretary Bose, Via Electronic filing

Subject: Ripogenus Project P-2572. Comments regarding Great Lake Hydro America's April 24, 2023 filing:; Appendix C: Initial Water Quality Study Report

The Licensee proposed, and then during 2022 conducted, water quality studies they hoped would provide information necessary in meeting statutory requirements in the Licensing of the Ripogenus Project and Penobscot Mills Projects. The Report is brief in needed fisheries related details and factually flawed in site locations. The lack of any information describing impoundment planktonic communities remains a major data gap.

As in other studies, the Licensee has sampled and provided interpretations of study results that fit its goals. This strategy is well within their rights as Licensee. It is the agencies, stakeholder and FERC staff that must argue for studies that describe the current status of fish and aquatic communities. Without realistic studies, the degradation of the Ripogenus Impoundment and West Branch of the Penobscot River (West Branch) will continue and the historic West Branch landlocked salmon (salmon) fishery will be a fishery of the past.

Aquatic insects provide food for all salmon life stages and are vital as summer "maintence diet" for adult salmon. Aquatic insect hatches of their former magnitude no longer exist. The Maine Department of Inland Fisheries and Wildlife October 8, 2021 filing states *"We have received anecdotal reports from anglers on the West Branch that insect hatches are less frequent and less intense than in the past. We think it would be prudent if the Licensee repeated the macroinvertebrate studies completed in the river for the current license to determine if any changes have occurred".* We think it would be prudent if the Licensee repeated the macroinvertebrate studies completed for the current license to determine if any changes have occurred. It is difficult to see why MeDIFW's reasonable request not was incorporated into the Water Quality study.

While not part of the Water Quality Study Plans, plankton communi. es continue to be the critical component of the Ripogenus Impoundment biota. Zooplankter, such as rotifers, support rainbow smelt, the key food source of impoundment and downstream salmon populations. Without a description of the Ripogenus Impoundment plankton communities the Maine Department of Environmental Protection will not be able to meet the "as naturally occurring"

or “anti degradation standard”. The 1991 Licensee Ripogenus Project Application contains a full description of the Impoundment’s planktonic communities.

The Licensee’s initial report was disappointing. As in previous studies of project uses, the Licensee alone sampled when, where, and how it collected data. Additionally, Ambejackmockamus Falls site is either miss named or miss located on the site map. This makes comparisons problematic. As with other Licensee studies, more “data gaps” are created rather than filled. While the Licensee states in the June 11. 2021 PAD that new studies are not needed: *“Therefore, GLHA maintains that a full suite of new studies is not needed, that the vast body of information on which today’s certifications and licenses are soundly based and should be relied upon for these relicensings. In addition, consistent with the Commission’s criteria for study requests, the scope and extent of any new study be focused on addressing specific data gaps necessary to inform the development of license requirements”.* This is not supported by the change in operations to a peaking mode

The Initial Water Quality Study Report of April 24, Appendix C provided West Branch of the Penobscot River (West Branch) aquatic communities information. Aquatic insects, namely Ephemeroptera, Plecoptera, and Trichoptera (EPT) are critical to the growth and survival of all West Branch salmon life stages. Additionally, the diversity and abundance of EPT is part of meeting water quality standards. River wide comparisons to 1991 data are impossible.

The basic goals of these studies were only to determine if water quality standards are being met. Studies designed to answer Agency and stakeholder questions regarding change resulting from the shift in Project operation to a peaking mode were not included. The 1991 FERC License Application provides tables demonstrating the abundance of aquatic insects in various river reaches. Additional sampling would allow past (1991 Application) and present (Appendix C) comparison between the abundance of aquatic communities, namely EPT.

The production of diversity and species richness indices are academically interesting. However, such indices do not provide information on the availability of aquatic insects as a food source to salmonid populations. These index tables deflect attention away from the paucity of aquatic insects critical to the West Branch salmonid food chain.

In an attempt to meet Water Quality Certification standards, rather than describe current conditions, the Licensee chose areas and methods NOT comparable to data presented in the 1991 Great Northen Paper License Application. In the draft study Plan, the Licensee proposed the Upper Gorge and Mckay Station as sampling sites. Two sites were added “in the vicinity of the Holbrook Side Channel and at Ambejackmockamus Falls to address the SPD

recommendation from FERC to add two river locations in the reach between McKay Station and Nesowadnehunk Falls."

These sites can be described as:

Upper Gorge; A ledge reach with seasonal flow
McKay Station; A man-made open culvert blasted from ledge
Holbrook Pool: An area bulldozed during the log-driving era
Ambejackmockamus Falls: From the photo on page C-45 it appears the Licensee has erred. The "bullet" on the map appears to be located at or near Little Falls approximately one mile above Big Ambejackmockamus Falls.

Except for one of the confusing "Big A" sites, none of the selected reaches represent the riffle, run, pool areas of the West Branch. These areas provide much of the Spring through Fall salmonid habitat.

Initially the reach below McKay Station was selected as a sampling site. The selection of this open culvert, high velocity area is somewhat of a mystery. Planned sampling was abandoned "GLHA did not perform an initial transect evaluation across the river directly downstream of McKay Station due to unsafe access conditions created by high velocity river flows. In addition, because this river reach is frequently recreated by whitewater rafters and boaters, dataloggers deployed in the center of the river would be in the direct path of boaters, creating an obstruction and safety hazard to boaters and potentially damaging the data logger" (C-32). The excuse provided is nonsensical. Channel configuration and McKay outflows have been on record for 70 years. Boaters and rafters have been present for 30 plus years. The Licensee was fully aware, or should have been fully aware, of these conditions when the McKay Station reach was proposed. The Licensee bares full responsibility for poor site selection and the lack of information from this site.

While this filing contains many high-quality pictures, neither "Holbrook" nor the "Ambejackmockamus" sites were photographed. While GPS coordinates are provided, these site locations need to be provided in "lay terms," photographed. The Licensee is responsible for knowing where they sampled.

Depending on how the text or map is read, the Licensee summarizes aquatic insect collections from either Big Ambejackmockamus Falls or Little Ambejackmockamus Falls, two very different habitats. The Locations are a mile apart as are any comparison with data shown in Tables 34 and 37 (edited) of the 1991 Ripogenus Project Application and the Licensee 2022 data. The number of Trichoptera taxa reported in Appendix C (Table 5.2 -30) is five as opposed to eight taxa reported in the 1982 sample. EPT species consisted of 11.6% of the Licensee's 2022 sample as opposed to an average of 45% in the May, June, sampling of 1982 (Table 37, 1991 Rip Application). A reasonable conclusion is that present project peaking operations have

degraded both species composition and abundance. The Licensee states “nothing has changed” (since the change in project ownership) in Project operations and river flow management. Notwithstanding the absurdity of this claim, how does the Licensee explain the change in taxa? The burden of proof lies with the Licensee. To date, fragmental data presented in Appendices three and four suggest a degraded fish and aquatic community in both the Ripogenus Impoundment and downstream West Branch.

A sampling scheme designed to duplicate Table 35 as well as Tables 34 and 37 would determine the present abundance of aquatic insects critical to salmonid management. The results of new sampling could meet the “naturally occurring” standard met in the 401 WQC of 1991 Ripogenus Project License. The Licensee’s Appendix C filing fails to provide data comparable to historic 1981-1984 aquatic insect species composition and abundance.

Table 35 shown below and from the 1991 Application provides useful information on taxa collected in 1982. Ephemeroptera and Trichoptera (Mayflies and Caddis flies) dominated the Surber samples. These are the insect Orders that salmon and, to a lesser degree, brook trout depend on as a food source. Salmon and trout are the species of MeDIFW’s Ripogenus Project management goals that focus on growth, survival, and spawning escapement. EPT abundances determine if these goals are being met.

TABLE 35. BENTHIC MACROINVERTEBRATE DENSITY (INDIVIDUALS . $m^{-2}$) AND PERCENT COMPOSITION (%) COLLECTED WITH MID-CHANNEL SURBER SAMPLES, 25-27 JUNE 1982 IN THE WEST BRANCH OF THE PENOBSCOT RIVER, PISCATAQUIS COUNTY, MAINE.

*represents a mean of 3 replicate samples

For the reasons stated above, FERC should require that the Water Quality Study be corrected and expanded in the final study Report. Meaningful West Branch aquatic communities' data, comparable to data presented in the 1991 License Application should be collected and presented in tabular form. In addition, planktonic populations of the Ripogenus Impoundment should be described in a manner comparable to information presented in the 1991 Application.

Thank you for the opportunity to comment and suggest a path forward that will provide meaningful information for the agencies and stakeholders.

Kimberly D. Bose, August 14, 2023
Secretary
Federal Energy Regulatory Commission
888 First Street, NE
Washington, DC 20426

Dear Secretary Bose, Via Electronic filing
Subject: Ripogenus Project P-2572. Rebuttal of GREAT LAKES HYDRO AMERICA, LLC RESPONSES TO COMMENTS ON THE INITIAL STUDY REPORT AND REQUESTS FOR NEW OR AMENDED STUDIES RIPOGENUS HYDROELECTRIC PROJECT (FERC NO. 2572) PENOBSCOT MILLS HYDROELECTRIC PROJECT (FERC NO. 2458) GREAT LAKES HYDRO AMERICA, LLC, August 7, 2023

The following comments deal only with the Ripogenus Project. Comments dealing with the North Twin Project will be provided in separate filings.

The Licensee's August 7, 2023 legally crafted response to study comments and requests is an argument that misrepresents facts and information provided by the Maine Department of Inland Fisheries and Wildlife (MeDIFW). Furthermore, in citing various statutes the Licensee ignores the fact that the Maine Water Quality Certification (WQC) process includes narrative standards. The Licensee is desperately attempting to avoid any facts that would disprove claims made regarding the Ripogenus Project's current peaking operation and the concurrent impoundment drawdown. The Licensee has consistently rebuffed all attempts to collect quantitative angler use and catch (a designed use) as well as quantitative fish and aquatic communities' data. The Licensee's arguments are based on information and assumptions that are simply false.

The Licensee's discussion of a Creel Survey Study (4.1) is a classic example of the failure to understand fisheries management methods, and goals. In an attempt to circumvent the angler use and catch issue, the Licensee added "angler questions" to the Recreational Study. This will not meet the necessary WQC standard. The Licensee continues to call angler survey boxes "creel surveys." Simply put, the Licensee is attempting to revise history and turn subjective judgement into quantitative data.

Angler surveys are common fishery management tools and are used at various levels of intensity e.g., mail survey, angler boxes, aerial surveys, and on-site creel surveys with face-to-face contact occurring on a daily

schedule. In their June 30, 2023 letter MeDIFW discussed a much-needed creel survey and begged for funding.

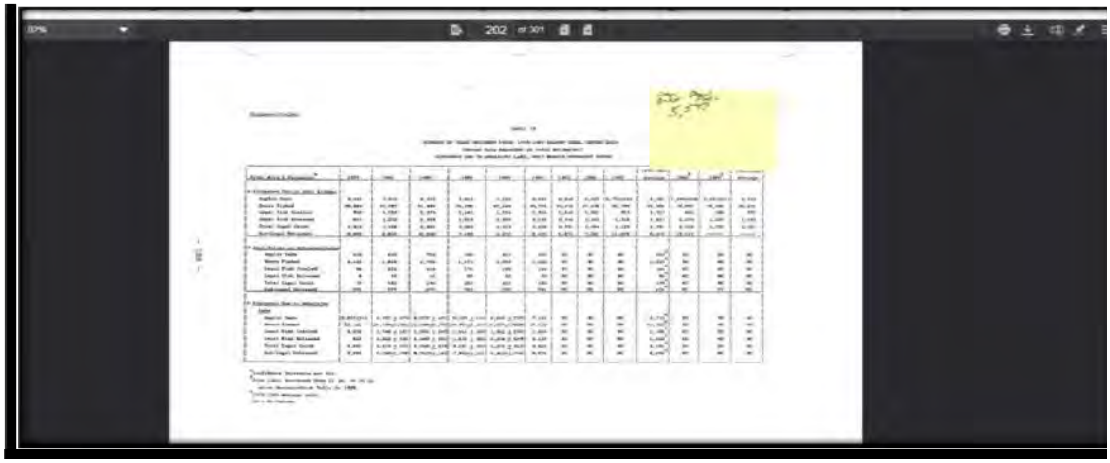
*MDIFW plans to periodically collect CPUE data on the West Branch of the Penobscot in the future. Therefore, we must rely on a repeatable survey method. While it would be desirable to have the sufficient staff to conduct full clerk surveys (emphasis added) on this large, important river (and many other locations in the Region), it just is not feasible due to current staffing levels.*

Th Licensee does not seem to understand the difference between voluntary angler survey boxes and creel surveys. The former is passive and depends entirely on angler cooperation and is subject to prestige bias (only successful anglers respond) as well as (angler) fabrications. The latter is direct angler contact where even non cooperative anglers are counted. Angler survey boxes provide "trends"; the same biases are repeated from year to year. Angler creel surveys require the angler to respond to a number of questions e.g. time fished, legal fish caught, sub-legal fish caught, size information and riverine reach fished. Anglers need not find a pencil or flashlight to respond. Creel surveys are robust, and they collect a variety of fishery parameters. Any survey method that does not collect catch per unit effort, (e.g. enumerate anglers and their effort), catch, and river reach is not an appropriate method to judge a fishery in decline or to form the basis for a thirty-year license.

In a classic miss-use of data, the Licensee uses MeDIFW angler survey box information as a description of the current West Branch fishery.

Angler Census Boxes – West Branch Downstream of McKay Station (multiple locations) 2021
-Anglers reported catching 864 Landlocked Salmon and 182 Brook Trout; Landlocked Salmon ranged from 5 to 21 inches long; Brook Trout ranged from 5 to 8 inches long
Angler Census Boxes – West Branch Downstream of McKay Station (multiple locations) 2022
Anglers reported catching 748 Landlocked Salmon and 76 Brook Trout; Landlocked Salmon ranged from 5 to 24 inches long; Brook Trout ranged from 5 to 8 inches long

It should be noted that survey box fish lengths are estimates provided by anglers.



From these MeDIFW data, it is impossible to determine if angling success has improved, declined, or remained constant since 1991. If trends are considered, angler success appears to have declined in 2022 when compared to 2021.

Worldwide, nationwide or in Maine, anglers typically fish for bigger fish, i.e. legal size or trophy size. Fishery management goals commonly focus on

the abundance/availability of legal-size fish. As they are not the target of most anglers, the abundance of sub-legal fish, salmon in this case, is of minor importance. The inclusion of sub-legal salmon in the MeDIFW's data in an attempt by the Licensee to obfuscate angler success.

Table 39 shown below is taken from the Ripogenus Project 1991 Application and provides a robust estimate of West Branch angler use (angler days), effort (hours fished) and catch (legal and sub-legal salmon). Unfortunately, there are no current data available for comparison purposes.

Table 39. Creel Survey Data found in the 1991 Ripogenus Project License Application Vol IX, Landlocked salmon, Angler effort and Catch

From the above table, the average 1979-1987 use was an estimated 6,254 angler days, and the estimated catch was 2,954 legal size salmon (the length limit changed in 1986). An addition 8,245 sub-legal salmon were released. The best year in total catch was 1984 where 6,546 anglers caught 3,628 legal sized salmon and 8,450 sub legal salmon were released. The MeDIFW angler survey boxes that I observed along the river were in prime locations. MeDIFW site selection was reasonable but adds additional bias. Tabular angler use and catch material is presented by riverine reach in IX of the 1991 Application, but 2021-22 catch by survey **box locations are not presented by the Licensee, no direct comparison can be made.** Still when historic data are compared to the 2021-22 MeDIFW results, the West Branch Fishery has been seriously degraded by the change in Project operations.

MeDIFW is “comfortable” with their knowledge of the West Branch fishery. This is a term of art. Management (catch and size limits) of a fishery can be adjusted based on the reported survey box catch. This is appropriate for some trout ponds but not major fisheries. For the West Branch, “a large Important River” (MeDIFW), “comfortable” is not based on the salmon population size, survival, or age and growth data as none exist. MeDIFW is truly underfunded, and they clearly emphasized their desire to conduct a West Branch creel survey in their June 30, 20023 filing should funds become available. Despite MeDIFW’s comfort level, not to be confused with knowledge of population structure, age and growth and food habits, licensing standards are not being met. Existing West Branch salmon (and aquatic community) information fails to meet the level of detail required in issuing a 30 year license.

On July 7, 2023 a McKay station outage produced disastrous environmental impact on fish and aquatic communities, and anglers. Impacts of the outage flows e.g., loss of young-of-the-year salmon, may last three to five years. This outage event combined with the total lack of current quantitative data on West Branch angler use and catch information begs for on-site creel survey data.

The Licensee has proved their lack of ability in conducting West Branch surveys e.g. the failure to collect scale samples during the fish assemblage studies, selection of the McKay Station water quality study site, and mass confusion between the Little Ambejackmockamus and Big Ambejackmockamus Falls Water Quality sampling site. The Licensee is conflicted and should not be entrusted to conduct a creel survey, a survey that might further damage its legal positions. Clearly, this is a task that is best suited for MeDIFW. FERC should require that the Licensee fund an entry level (Moosehead Region) fishery position dedicated to the Ripogenus Project with the primary obligations to a West Branch creel survey (and smelt drift net collections).

For over two years the Licensee has told the agencies and stakeholder that nothing has changed and that all impoundments are riverine reaches exist as they did 35 years ago. This pipe dream is simply posturing. The Licensee has filed its pages of response with legal standards. New studies that would provide, in this case, fisheries information, have been fought at every opportunity. In the interim, the Ripogenus Project fish and aquatic communities suffer. The burden of proof lies with the Licensee.

For the reasons stated above, FERC should reject the Licensee's RESPONSES TO COMMENTS ON THE INITIAL STUDY REPORT dated August 7, 2023. FERC should reject the often repeated arguments that opposed robust West Branch creel surveys. There is a clear need to define recreational anger use (days fished), effort (hours fished) and catch (legal and sub-legal salmon and brook trout caught) and river reach fished.

Thank you for the opportunity to comment.

RE; Ripogenus Project, FERC No. 2572; Response to Allegations of Flow Deviations filed August 11, 2023

Great Lakes Hydro America's (Licensee) response to FERC's August 4th letter concerning the Jully 7th McKay Station outage and subsequent low flow violation. This filing of events during that outage flow provides some useful information but fails to deal with serious environmental issues. The Licensee doesn't provide evidence that outage flow of 400 cfs were met. The Licensee also failed to provide a detailed time line and methods that dealt with restoration of river flow. More importantly, FERC requested details of environmental impacts are ignored.

The referenced lighting strike outage of July 7 was ill-timed and an unfortunate event. The Licensee lost the ability to generate from two turbines and had to stunt water downstream to meet North Twin impoundment elevation requirements. The fish and aquatic communities were devastated. In short, both an energy production and environmental disaster. A lose-lose situation.

As noted in earlier filings, impact from this outage event could have been prevented/reduced had Ripogenus Dam gates been fitted with back-up emergency generators. A few dollars were needed to protect environmental resources. Environmental concerns were ignored.

The Licensee's August response to FERC contains the often-repeated license requirements but is short in critical details. Licensee maintains that West Branch River flow never dropped below 400 cfs. They say that while noting the station was both unmanned and off-line. Pictures of the river, dead fish, and angler/camper observation suggest this was not the case. As explained below, the licensee needs to provide critical July 7th information.

The Licensee has provided hourly average flows for the five-hour outage period and flows immediately before and after this event. While "hourly

averages" meet license reporting standards, low flows can be obscured by averaging. From my past experience, there is a transition period between McKay Station outage and start-up emergency flows. Additionally, the 610 cfs flow appeared to calculated from gate settings. This is concerning given that the station was unmanned and "off-line" during the first hours of the outage event. The requested chronology and manning of the License's july7th response was not provided. This information is cri. cal. How was the 13% Wicket Gate flow(s) confirmed? When I last entered the scroll case, there was much debris. There is always some variation in flows, if only from the Ripogenus log sluice gate setting of 100 cfs. How can an exact flow average of 610 cfs over a four hour period be possible?

From tabular flow information provided by the Licensee in their August 11th, outage report reply state flows remained at 610 cfs for five hours. No reason is provided for the five hour delay in opening a Ripogenus Dam deep gate. This inexcusable delay exasperated the impacts on fish and aquatic communities. The Licensee's October 2022 Outage Study demonstrated severe impacts to fish and aquatic communities. The July 7th outage was even more diasterous, recently emerged Landlocked salmon (salmon) fry (alevin) are extremely vulnerable to dewatering and the rapid rise of river flow.

The licensee failed to respond to or even note, the apparent violation of Article 406, the Holbrook Bypass Channel spawning and nursey area. Low flows for the duration of the five hours reported by the Licensee, dewatered this critical salmon nursey area. While FERC may conclude that this event was not a license violation, the fact remains that a year class of recently emerged landlock salmon was lost. The impact of the July 7 flow on newly emerged salmon occurred in all river reaches. The loss of a salmon age class impact could last for three to five years.

The FERC letter inquired about environmental impacts "*Please describe the methods used to check for environmental effects, including the areas surveyed*". The Licensee failed to respond to this reasonable request. To date, the reported incident of fish kills is from boaters and anglers. The impacts of a 5:59 PM outage would be delayed, evidence of fish kills would generally appear later in the evening. Ripogenus Dam gate flows that were increases at 11PM would normally wash downstream fish and insect caraccas and obscure much of the dewatering impacts. It is clear the July 7th outage produced fish and aquatic insect kills. FERC should err on the side of the resource when considering adjudicating damages.

As has been the case in these (re) Licensing proceeding the Licensee answers and provides data that suits its needs. FERC asked for additional data, information concerning environmental damage. Rather than admit that they were not on-site, and have no information to report, the licensee ignores the request. Environmental damage resulting from the July 7th "lighting strike" (somewhere in the Grid) is evident, I encourage FERC to purse requested information.

Thank you for the opportunity to comment. Please continue to purse this matter in an aggressive manner.

RE; Ripogenus Project, FERC No. 2458-136; Great Lakes Hydro America's Response to Requested Studies: **4.3 North Twin Tributary Access Study using Radio Telemetry**

**Dear Secretary Bose,**

**One of the Maine Department of Inland Fisheries and Wildlife's (MeDIFW) initial study requests was for the study of North Twin Impoundment landlocked salmon (salmon) pre-spawning behavior through the use of radio tags. The questions were: movement of North Twin Impoundment salmon, locations of spawning tributaries, the impact of water level management on salmon passage into tributary streams, and possible shoreline spawning. Only one phase of this study was approved. The Licensee has repeatedly sought to prevent collection of meaningful salmon spawning behavior though the use of radio telemetry.**

**In a July 4, 2023 filing, I commented on the Licensee's refusal to conduct this reasonable radio tagging study. Other than the Licensee seems focused on salmon shore spawning, little has changed.**

**As presented, the Licensee's proposal is a salmon spawning study without salmon!!! It is guesswork to determine where (and when) salmon that created redds originated. Redds in Nahmakanta stream could be from Nahmakanta or Jo-Mary Lakes, the West Branch, or from the North Twin Impoundment salmon (or even brook trout). Direct or indirect (data loggers') observations of radio tagged salmon spawning or about to spawn in tributary locations will confirm "access" questions.**

**Consistent with the Licensee's denial of other requested studies, interpretations of legal statutes are used rather than science-based**

**facts. The 1991 License Application provides search results from possible tributary spawning locations as well as potential barriers resulting from impoundment fluctuations. Boulders, ledges, and rocks in tributary streams remain as they were during earlier studies. The Licensee was aware of the results of the "access" component of MeDIFW's request and knew there were no physical barriers. However, the Licensee accepted MeDIFW's Tributary Study request with major modifications. Realistically, as the study is now presented, the Licensee should simply reference the 1991 Application, as no new information will be provided. Without telemetry, salmon shore spawning will be inconclusive.**

**The key to the MeDIFW tributary access request was more about behavior rather than the salmon's ability to access certain spawning areas and possible shore spawning. These two questions require radio telemetry. A salmon response to lake level management under a variety of scenarios could alter traditional spawning staging locations. Such areas might be too shallow or alternately too deep. Predation could be increased; fish could wander off. Shore spawning is much less likely. As noted by Boucher 2012, . Maine Landlocked Salmon: Life History, Ecology, and Managemen**t, "Salmon prefer lake outlets or large inlets for spawning, but where these are lacking, they may utilize lake shoals or small inlets, though production from these areas is generally very low". The Licensee failed to provided peer reviewed information: physical, thermal, or chemical data that describe possible shore spawning search criteria. The Licensee's suggestion that possible shore spawning areas can be visibly identified is both labor intensive and absurd.

The Licensee argues that "Pursuant to the July 26, 2012 Order Amending Ar. cle 408, from August 22 to October 15,"(PAD 4-48), "the fall drawdown has generally been limited to 2-3 feet in magnitude, limiting the potential impact to spawning areas". This is yet another attempt to obfuscate the issue. Salmon spawn in November and spawn in stream habitats not subject to impoundment elevation. Additionally, the legislature's charter flow requirement of 2000 cfs "by Millinocket" appears to supersede drawdown restrictions.

With the exception of the historic West Branch Channel where the Licensee attempted to change fisheries management goals to Brook trout, the Licensee has fought all studies that would provide information on current operations. The thought of radio tagged salmon swimming around the

North Twin impoundment terrorizes the Licensee as it may limit its free hand to sell the public water for its generation value. So be it. Radio tagging of North Twin impoundment salmon source fish will identify spawning staging areas, and any behavioral changes brought on by water level management and the presence or absence of shore spawning. Should (tagged) North Twin salmon move into the West Branch, then McKay Station spawning flows could be considered an additional Ripogenus Project enhancement.

Additionally in the early 2000s, the licensee (Normandeau Associates) used radio tagged salmon and Brook trout to study movement when Licensing the Moose River of the Brassua Project (P 2615). The North Twin Impoundment study goals are similar Moose River Salmon movement and spawning questions.

Should FERC staff decide that radio telemetry is not needed, the study is meaningless as it provides no new information. If this is the case, I urge MeDIFW to withdraw its study request. As presented the Licensee's proposed tributary study is a sham. Any study that produces no new information is a waste of time and resources resolving the issues. I urge FERC to respond accordingly.

Thank you for the opportunity to respond.

**Re: MDIFW Clarification on GLHA Response to Comments on the Initial Study Report and Requests for New or Amended Studies for the Ripogenus Hydroelectric Project (FERC No. 2572) and Penobscot Mills Hydroelectric Project (FERC No. 2458)**

Dear Secretary Bose:

On August 7, 2023, Great Lakes Hydro America, LLC (GLHA), a subsidiary of Brookfield Renewable, submitted their Response to Comments on the Initial Study Report and Requests for New or Amended Studies for the Ripogenus Hydroelectric Project (FERC No. 2572-133) and Penobscot Mills Hydroelectric Project (FERC No. 2458-247).

The Maine Department of Inland Fisheries and Wildlife (MDIFW) appreciates that GLHA has adopted our Umbazooksus Lake Mitigation Evaluation Study Plan. However, it was "Adopted as Requested or with Modification" for the following reason:

> *"GLHA notes that the current mitigation measure implemented at Umbazooksus Lake consisted of permanently opening the discharge gate to lower the lake level and increase the wetland habitat at Umbazooksus Lake. If the water surface elevation of Umbazooksus Lake was raised, it would decrease the wetland habitat. Therefore, GLHA did not adopt MDIFW's request to evaluate the change in habitat resulting from a potential increase in water surface elevation at Umbazooksus Lake."*

GLHA did not provide information to support the claim that by adding water on this impoundment it would decrease the total acres of wetlands, and MDIFW does not agree with this statement. Our limited analysis of aerial imagery indicates that by adding water on the impoundment there would be an increase in the level of *interspersion* in these areas at a minimum, if not *increase* the total acres of wetlands. We believe that by increasing the interspersion of these fringe wetlands through higher lake levels, wetland function will improve in these areas and, over time, increase the acres of emergent and aquatic bed. These are important wetland types that are found in higher quality wetlands and would support a diversity of wildlife including waterfowl, wading birds, and aquatic furbearers. In addition, they are the wetland types that seem to be noticeably absent, or are of very low quality, in larger hydroelectric impoundments in projects managed similar to the Ripogenus Project.

Please feel free to contact my office if you have any questions regarding this information, or if I can be of any further assistance.

Best regards,

John Perry

**Subject:** **Ripogenus Hydroelectric Project (FERC No. 2572-133)**
**Penobscot Mills Hydroelectric Project (FERC No. 2458-247)**
**Response to MDIFW Comments on Requested Umbazooksus Lake Mitigation Evaluation Study Plan**

Dear Secretary Bose:

Great Lakes Hydro America, LLC (GLHA), the Licensee of the Ripogenus Hydroelectric Project (No. 2572) and the Penobscot Mills Hydroelectric Project (No. 2458) (collectively referred to as the "Projects"), herein files with the Federal Energy Regulatory Commission (FERC) responses to comments filed by the Maine Department of Inland Fisheries and Wildlife (MDIFW) on August 25, 2023 related to the Umbazooksus Lake Mitigation Evaluation Study Plan. The Projects are located on the West Branch of the Penobscot River and Millinocket Stream in Piscataquis and Penobscot counties, Maine.

In their August 25, 2023 letter, MDIFW indicated that GLHA did not provide information to support the claim that adding water to Umbazooksus Lake would decrease the total acres of wetlands. As such, GLHA reviewed the Wetland Enhancement Plan (filed with FERC on October 21, 1997) and the Umbazooksus Lake Wetlands Enhancement Final Report (filed with FERC on May 31, 2005) pursuant to Article 408 and 410 of the licenses for the Ripogenus and Penobscot Mills Projects, respectively.

As indicated in the 1997 Plan, "The objective of wetland enhancement at Umbazooksus Lake will be to substantially increase the extent, density, and species diversity of wetland vegetation cover within the zone from the former full pond elevation down to approximately six feet below ordinary low water. This will be achieved by lowering the average water level of the impoundment, establishing a more consistent hydrologic regime from year-to-year, and reducing the variability of water levels during the growing season of any given year. These changes are expected to enhance the ability of the existing wetlands to perform wetland functions such as wildlife habitat, production export, water quality enhancement, and shoreline protection, and are also expected to lead to the establishment of emergent and aquatic bed wetlands in previously unvegetated areas." Also as indicated in the 1997 Plan, the wetlands that existed at Umbazooksus Lake under the prior water management and higher water levels were limited to fringe emergent and shrub wetland types around the shore of the impoundment. Due to the lake's bathymetry, including a lake bottom that is largely flat or gently sloping, a lowered water level was agreed upon through agency consultation to enhance the fringe wetland types that existed at the time and to establish new emergent and aquatic bed wetlands within the lake.

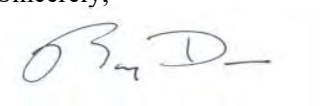
T +1 207.723.4341 F +1 207.723.4597 brookfieldrenewableUS.com

As indicated in the 2004 Final Report, "The 320 acres of wetlands that had been degraded by the former operational regime are now well on their way to recovery. Vegetation cover (density) has increased in all vegetation zones, including a substantial increase in the E/F zone since 1998. Overall, vegetation cover (i.e., density) has increased over 350 percent. The conversion of many areas from E to SS/E cover, and the overall increase in the species richness and density of trees and shrubs, indicate that plant community succession is occurring in the areas formerly affected by flooding, and an inward/downward shift of cover type zones is underway. In addition, the total extent of vegetated wetlands surrounding Umbazooksus Lake has so far increased by approximately 117 acres since 1998. This is the result of emergent and floating-leaved vegetation expanding into newly available shallows created by maintaining the gate in a permanently open position." The final report, which was based on wetlands monitoring from 1998-2004, demonstrated the considerable increase in shallow areas in Umbazooksus Lake (less than 6 feet deep, and estimated to be 280 acres) that resulted by lowering the water level and which were expected to eventually support wetland vegetation. FERC approved this final report on December 20, 3005.



GLHA believes MDIFW's request to evaluate higher water levels at Umbazooksus Lake are in conflict with the original intent and design of this mitigation measure that was determined through extensive consultation with resource agencies and subsequent monitoring that verified the intended results.

Alternatively, GLHA is proposing a study to collect contemporary data at Umbazooksus Lake to evaluate the current conditions in relation to the intended mitigation measure and the current relicensing of the Projects.

Concurrent with this filing, GLHA is providing a copy of this letter to all parties listed in the attached distribution list. Parties can download an electronic copy of this filing from FERC's eLibrary system at https://www.ferc.gov/ferc-online/elibrary by conducting a search using the docket numbers P-2458 and/or P-2572.

If you have any questions regarding this filing, please contact me by phone at (207) 775-5605 or by email at randy.dorman@brookfieldrenewable.com.

Sincerely,

Randall Dorman, Licensing Manager

OFFICE OF ENERGY PROJECTS

Project Nos. 2572-133 & 2458-247 –
Maine
Ripogenus Hydroelectric Project
Penobscot Mills Hydroelectric Project
Great Lakes Hydro America, LLC

VIA FERC SERVICE

Mr. Randy Dorman, Relicensing Manager
Brookfield Renewable
150 Main Street
Lewiston, Maine 04240

**Subject: Determination on Requests for Study Modifications and New Studies for the Ripogenus and Penobscot Mills Hydroelectric Projects**

Dear Mr. Dorman:

Pursuant to 18 C.F.R. § 5.15 of the Commission's regulations, this letter contains the determination on requests for modifications to the approved study plan and new studies for the proposed relicensing of Great Lakes Hydro America, LLC's (GLHA) Ripogenus and Penobscot Mills Hydroelectric Projects (collectively, the "Projects"). The Projects are located on the West Branch of the Penobscot River and on Millinocket Stream in Piscataquis and Penobscot Counties, Maine. The determination is based on the study criteria set forth in sections 5.9(b), 5.15(d), and 5.15(e) of the Commission's regulations, applicable law, Commission policy and practice, and Commission staff's review of the record of information.

Background

The study plan determination (SPD) for the project was issued on May 13, 2022, and required GLHA to conduct 24 studies, including a *Water Quality Study* comprising five components, and file an initial study report (ISR) on those studies by May 13, 2023.

GLHA filed the ISR on April 24, 2023,[1] and held study report meetings on May 2-4, 2023, to present the ISR results, and filed a summary of the meeting on May 22, 2023.

Comments

Comments on the ISR and meeting summary, including requests for new studies, were filed by: the National Marine Fisheries Service on July 10, 2023; the Maine Department of Inland Fisheries and Wildlife (Maine DIFW) on June 29, 2023; the Maine Department of Marine Resources on July 6, 2023; the Maine Bureau of Parks and Lands on July 6, 2023; the Maine Council of Trout Unlimited (Maine TU) on July 5, 2023; American Whitewater and Appalachian Mountain Club on July 6, 2023; Maine Professional Rafting Outfitters on July 6, 2023; the Caribou and Chesuncook Lake Camp Association, Chesuncook Village Association, and the Chesuncook Dam Camp Association on June 20, 2023; Christopher Howe on July 6, 2023; Jeff Kaine on June 8, 2023; and Edward Spear on June 5, 2023, June 30, 2023, July 5, 2023, July 6, 2023, and July 7, 2023. GLHA filed reply comments on August 7, 2023. On August 15, 2023, and August 18, 2023, Edward Spear filed responses to GLHA's August 7, 2023 filing. On August 25, 2023, Maine DIFW filed a response to GLHA's August 7 filing.

A number of the comments do not specifically request modifications to the approved studies or additional studies, and, therefore, are not addressed herein. For example, some of the comments provide additional information; recommend protection, mitigation, and enhancement measures; address potential effects on environmental resources; address ongoing and future consultation; express disagreement with the results of the studies, or how the data and results were presented; or request additional information that is contingent upon the results of incomplete studies. GLHA has subsequently provided some of the requested information in its reply comments and some will be provided in future filings. This determination only addresses new comments or requests to modify the study plan. This determination does not address requests for modifications to studies that were previously requested, but not required by the study plan determination (e.g., Maine DIFW's, Maine TU's, and Edward Spear's requests for an Atlantic salmon radio-tagging study).

Study Plan Determination

Pursuant to section 5.15(d) of the Commission's regulations, any proposal to modify a required study must be accompanied by a showing of good cause, and must include a demonstration that: (1) the approved study was not conducted as provided for in the approved study plan; or (2) the study was conducted under anomalous

[1] On February 17, 2023, Commission staff approved GLHA's request to modify the schedule for filing the ISR by moving the date up from May 13, 2023 to April 22, 2023. Because April 22 fell on a Saturday, GLHA timely filed the ISR on the next business day, which was April 24, 2023.

environmental conditions or that environmental conditions have changed in a material way. As specified in section 5.15(e), requests for new information gathering or studies must include a statement explaining: (1) any material change in law or regulations applicable to the information request; (2) why the goals and objectives of the approved study could not be met with the approved study methodology; (3) why the request was not made earlier; (4) significant changes in the project proposal or that significant new information material to the study objectives has become available; and (5) why the new study request satisfies the study criteria in section 5.9(b).

Appendix A summarizes the determination on the requested modifications to the approved study plan for 10 studies. Specific modifications to the studies and the basis for modifying them are explained in Appendix B. Appendix C provides the determination on the requests for eight new studies. Commission staff considered all study plan criteria in accordance with sections 5.9(b) and 5.15(d) and (e) of the Commission's regulations.[2] However, only the specific study criteria relevant to the determination are referenced in Appendices B and C.

Please note that nothing in this determination is intended, in any way, to limit any agency's proper exercise of its independent statutory authority to require additional studies. If you have any questions, please contact Allan Creamer at (202) 502-8365, or via email at allan.creamer@ferc.gov.

Sincerely,

JOHN WOOD

Director
Office of Energy Projects

[2] Additional time was needed to review and respond to filings that, among other things, requested eight new studies; therefore, pursuant to section 5.29(f)(2) of the Commission's regulations, section 5.15(c)(6) is waived to provide the additional time needed to address the required modifications to the approved study plan.

Enclosures: Appendix A – Summary of Determinations on Proposals and Requests to Modify Study Plan

Appendix B – Staff Recommendation on Requested Study Modifications

Appendix C – Staff Recommendations on Requested New Studies

Appendix D – Literature Cited

## APPENDIX A

## SUMMARY OF DETERMINATION ON PROPOSALS AND REQUESTS TO MODIFY STUDY PLAN

**Requested Study Modifications (*see* Appendix B for Discussion)**

## APPENDIX B

## STAFF RECOMMENDATIONS ON REQUESTED STUDY MODIFICATIONS

### 4. Water Quality Study

Background

The May 13, 2022, Study Plan Determination (SPD) required GLHA to conduct a *Water Quality Study* for the Ripogenus and Penobscot Mills Projects. The goals of the study were to: (1) collect current water quality data at the projects; (2) determine the composition of the projects' benthic macroinvertebrate[13] community; (3) determine the composition of the Ripogenus Project's fisheries community; and (4) collect aquatic habitat data at the projects. The specific objectives were to:

- determine the trophic state of the Ripogenus impoundment and the Penobscot Mills Project's five impoundments;[14];
- evaluate whether water temperature, dissolved oxygen (DO), and other water quality parameters (e.g., total phosphorus, chlorophyll-a) are meeting Maine water quality standards in: (1) the Ripogenus impoundment, the Upper Gorge (Ripogenus Dam to McKay Station), and McKay Station tailrace to 1,000 feet downstream; and (2) the Penobscot Mills Project area, including the impoundments, the project tailraces, the West Branch downstream from Stone Dam, and Millinocket Stream downstream from Millinocket Lake Storage Dam;
- demonstrate that the structure and function of the aquatic community within the Ripogenus impoundment, as determined from the composition of the benthic macroinvertebrate and indigenous fish communities, are maintained;
- determine whether 75 percent of the littoral zone of the North Twin impoundment and Millinocket Lake Storage impoundment remain watered during normal operations;
- demonstrate that existing minimum flows downstream from Stone Dam and Millinocket Lake Dam achieve applicable aquatic life standards;
- determine the composition of the benthic macroinvertebrate community within the

[13] Macroinvertebrates are animals lacking a backbone that are large enough to see without the aid of a microscope. They may be aquatic or terrestrial; the aquatic organisms often being larval or nymph forms of terrestrial species. Aquatic macroinvertebrates include annelids (segmented worms), mollusks (e.g., freshwater mussels), arthropods/crustaceans (e.g., crayfish), dragonflies and damselflies, stoneflies, mayflies, caddisflies, true bugs, beetles, true flies, and others.

[14] Millinocket Lake Storage, North Twin, Millinocket (Quakish Lake and Ferguson Pond), Dolby Pond, and East Millinocket impoundments.

Upper Gorge and the West Branch within 1,000 feet downstream from McKay Station, within the tailrace of each Penobscot Mills Developments, downstream from Stone Dam, and downstream from Millinocket Lake Storage Dam, and evaluate whether aquatic life criteria are attained; and

- determine if existing baseline minimum flow conditions in the Upper Gorge and in the West Branch immediately downstream from McKay Station provide aquatic habitat that meets the Maine Department of Environmental Protection (Maine DEP) hydropower guidance for riverine habitats.

The study area for the Ripogenus Project included the Ripogenus impoundment (and associated sub-basins), the Upper Gorge, and the McKay Station tailrace and river extending about 1,000 feet downstream. The study area for the Penobscot Mills Project included the North Twin impoundment and tailrace; the Millinocket impoundment and tailrace, as well as the West Branch downstream from Stone Dam; the Dolby impoundment and tailrace; the East Millinocket impoundment and tailrace; and the Millinocket Lake Storage impoundment and Millinocket Stream (to about 1,000 feet downstream from Millinocket Lake Storage Dam).

GLHA conducted the *Water Quality Study* in accordance with the SPD.[15] However, in the *Water Quality Study Report*, GLHA states that the macroinvertebrate sampling in the West Branch downstream from Stone Dam in 2022 did not yield sufficient data (numbers of macroinvertebrates) to document compliance with Maine's water quality standards.

Proposed Study Modifications

In response to comments received at the Initial Study Report (ISR) Meeting from the Maine Department of Inland Fisheries and Wildlife (Maine DIFW), GLHA, in 2023, installed water temperature loggers at three locations on the West Branch (about 0.1, 1.1, and 2.5 river miles) downstream from Stone Dam. The purpose of this monitoring is to determine the seasonality of ambient water temperatures adequate to support a managed fishery for cold water salmonids in the reach. Data were collected on an hourly basis during the monitoring period (June 8 to July 27) at the three locations. The results of the water temperature monitoring are to be provided in the Updated Study Report (USR).

As noted above, macroinvertebrate sampling in the West Branch downstream from Stone Dam did not collect enough macroinvertebrates for Maine DEP to run its macroinvertebrate model. Thus, GLHA is repeating the macroinvertebrate sampling in

[15] The details of the methodology used for the individual components of the study are provided in section 4.0 of the *Water Quality Study Report* [Appendix C of the Initial Study Report filed April 24, 2023].

the West Branch downstream from Stone Dam in 2023, per the methods in the approved *Water Quality Study*.[16]

Requested Study Modifications

In his comments on the *Water Quality Study*,[17] Edward Spear suggests that the information obtained from the study will not be sufficient to document compliance with Maine DEP's water quality standards. Mr. Spear asserts that the lack of information describing the Ripogenus impoundment plankton communities remains a data gap. Mr. Spear cites the following deficiencies in the study: (1) rather than describe current conditions, sampling areas and methods were chosen that do not allow for a comparison with data presented in the 1991 Great Northern Paper license application; (2) reaches selected for sampling do not represent the riffle, run, and pool areas of the West Branch; and (3) the *Water Quality Study* does not provide information to answer questions regarding changes resulting from a shift in project operation from the historical store-and-release mode to one of a peaking mode. To correct the alleged deficiencies, Mr. Spear requests that the *Water Quality Study* be modified to collect West Branch aquatic community data and sample plankton communities in the Ripogenus impoundment, presumably for the purpose of obtaining data comparable to that included in the 1991 license application.

In its comments, the Maine Council of Trout Unlimited (Maine TU) states that the study's objective to collect information sufficient to document compliance with Maine DEP's standards for aquatic life was not met,[18] and asserts that fresh data is needed to confirm the presence of native fish. In their comments, American Whitewater and Appalachian Mountain Club (AW/AMC) state that the study failed to: (1) achieve the study goal to determine if existing baseline minimum flow conditions in the Upper Gorge provide aquatic habitat that meets Maine DEP's hydropower guidance; and (2) show that the existing minimum flow provides sufficient wetted width in Millinocket Stream. However, neither entity provided details regarding modifications to the study plan.

Comments on Requested Study Modifications

In its reply comments, GLHA asserts that the *Water Quality Study* generally demonstrates that project waters meet Maine DEP's applicable water quality standards.

[16] GLHA conducted standard macroinvertebrate sampling in all project tailwater areas and reaches downstream from the project dams. All sampling was conducted using the same standard "bug-basket" methodology in accordance with Maine DEP protocols.

[17] *See* Edward Spear's August 10, 2023, Filing.

[18] Maine TU specifically identifies the following reaches: Upper Gorge, West Branch downstream from Stone Dam, and Ripogenus impoundment).

Regarding the Upper Gorge and Millinocket Stream, GLHA asserts that the studies completed in 2022 and other information in the ISR, achieved the study goal to determine if existing baseline minimum flow conditions [e.g., leakage from Ripogenus Dam (12 cubic feet per second (cfs)), as well as 100 cfs and 60 cfs from releases in the Upper Gorge and Millinocket Stream, respectively] provide aquatic habitat that meets applicable standards. For the West Branch downstream from Stone Dam, GLHA states that there is no evidence that the reach is "stagnant," nor are pools "disconnected" at any flow. Because aspects of the *Water Quality Study* are incomplete for the reach downstream from Stone Dam (e.g., macro-invertebrate sampling and flow modeling), GLHA states that it is premature to review conditions in the reach. Finally, GLHA commented on the attainment status of the Ripogenus impoundment only as it concerns the request for a *Smelt Study* in the impoundment (*see* discussion in Appendix C).

Discussion and Recommendation

The approved *Water Quality Study* is a comprehensive study designed to collect information on the impoundment's trophic state and aquatic habitat, riverine water quality and aquatic habitat, and benthic macroinvertebrate community. The study followed Maine DEP guidelines for collecting information needed to assess water quality relative to standards established by the state (e.g., wetted width standard) [section 5.9(b)6)]. In the Upper Gorge, transects were placed primarily in riffle/shallow run areas, which are more responsive to changes in flow than deep pools or deep runs. Transect locations were selected to represent limiting conditions at low flow for fish that may volitionally move in and out of the reach; thus, addressing zone-of-passage conditions. Transect habitat data[19] (collected in wadable areas of the reach) and drone footage show that adequate water depth and zone-of-passage conditions exist for resident fish species that inhabit the reach. For Millinocket Stream, data collected in 2022 show that the 60-cfs minimum flow provides adequate water depths and zone-of-passage conditions for resident fish inhabiting the reach.[20] Finally, there were 13 transects located within the two study reaches on the West Branch downstream from Stone Dam.

[19] Average water depth across the three transects at the leakage flow ranged from 0.7 to 1.4 feet (8.4 to 16.8 inches), and maximum depths ranged from 2.5 to 3.6 feet. Moreover, the Hilsenhoff Biotic Index value calculated for the macroinvertebrate community in the Upper Gorge was 3.46, which supports a finding of "Excellent" water quality and degree of organic pollution (Hilsenhoff, 1987).

[20] The existing 60-cfs minimum flow provides 90% to 91% of the streams wetted width, compared to bank-full conditions. Based on the cross-sectional plots of the stream bed and banks, the 60-cfs minimum flow provides a maximum depth of 1.6 feet (19 inches) and average depths of 0.6 feet and 0.7 feet (7.2 inches to 8.4 inches) at the two study transects. The Hilsenhoff Biotic Index value was 4.59, supporting a finding of "Good" water quality and degree of organic pollution (Hilsenhoff, 1987).

Overall, the portion of the study completed by GLHA in 2022 met the study goal of assessing the extent to which existing baseline minimum flow conditions provide adequate aquatic habitat relative to applicable standards [section 5.9(b)(1)]. Moreover, the study was conducted as required by the SPD, and the study was not conducted under anomalous environmental conditions, nor have the environmental conditions changed in a material way [section 5.15(d)(2).

Regarding Mr. Spear's request for a Ripogenus impoundment plankton study, this was not a goal of the approved *Water Quality Study*, nor was collecting comparable information to the data collected for the 1991 license application part of the approved study [section 5.9(b)(1)]. As to the plankton study, we stated in the SPD that there was no reason to suspect that any adverse effects on zooplankton[21] are specifically and directly related to lake level management in the Ripogenus impoundment. The studies completed in 2022 do not provide any information to establish such a connection [section 5.15(c)(4)]. Moreover, the limited information obtained from one season of zooplankton sampling would not be sufficient to answer the questions posed by Mr. Spear [section 5.9(b)(5)]. For these reasons, we do not recommend Mr. Spear's recommended modifications to the *Water Quality Study*.

With respect to Maine TU's request for additional information to confirm the presence of native fish, we address this request below, finding it unnecessary, as part of our discussion of the *Fish Assemblage Study*.

Finally, the approved macroinvertebrate data collection efforts were not completed in the West Branch downstream from Stone Dam in 2022. Moreover, the adequacy of the reach (i.e., seasonal water temperature) to support a seasonal salmonid fishery is a question that still needs to be addressed. GLHA's proposals to complete the required macroinvertebrate sampling downstream from Stone Dam and to collect water temperature data in the reach would provide important data to inform development of license requirements [section 5.9(b)(6)], and the additional temperature monitoring would not add significantly to the cost of the study [section 5.9(b)(7). Therefore, we recommend the required macroinvertebrate sampling be completed in 2023, and the approved *Water Quality Study* be modified to include the additional West Branch temperature monitoring proposed by GLHA.

[21] Zooplankton are small, aquatic microorganisms in the water column that include crustaceans, rotifers, open water insect larvae, and aquatic mites.

## 5. Fish Assemblage Study

Background

The SPD required GLHA to conduct a *Fish Assemblage Study* for the Ripogenus and Penobscot Mills Projects to fill certain data gaps. The study included both desktop (review of existing information) and field sampling components. The specific goals and objectives of the study were to: (1) provide contemporary data to assess the potential effects of the proposed relicensing of the projects on the fish assemblage in the project areas; and (2) use the information to determine if the Ripogenus impoundment maintains an indigenous fish assemblage. For the Ripogenus Project, field sampling was determined to be necessary. Sampling areas included: (1) the six sub-basins of the Ripogenus impoundment,[22] the Upper Gorge, and the West Branch from McKay Station downstream to Nesowaduehunk Falls. For the Penobscot Mills Project, available fisheries data were assembled. Areas from which existing fisheries data were assembled included all the project impoundments, as well as the West Branch downstream from Stone Dam, the West Branch downstream from Dolby and East Mill Dams, and Millinocket Stream downstream from Millinocket Lake Storage Dam.

GLHA conducted the *Fish Assemblage Study* in accordance with the SPD, with one significant exception: no spring sampling occurred at the Ripogenus Project. Otherwise, methodology employed as part of the study varied with sampling location.[23] Sampling techniques used during the summer and fall of 2022 for the Ripogenus impoundment included boat electrofishing and trap netting. Boat electrofishing was conducted during the evening or nighttime hours in nearshore and shallow water habitats. Trap netting was conducted to supplement the boat electrofishing within the Ripogenus impoundment. During each sampling season, trap nets were deployed at a total of five tributary confluence locations throughout the impoundment. Species richness and composition, relative abundance, and, for selected fish species, size distributions were calculated. The condition of landlocked salmon was also assessed. Sampling in the Upper Gorge included minnow traps, angling, and backpack electrofishing, with the condition for all captured salmonids being calculated. In the West Branch downstream from McKay Station, sampling methodology followed that described in Yoder *et al*.

[22] Ripogenus Lake, Caribou Lake, Chesuncook Lake, Moose Pond, Brandy Pond, and Black Pond.

[23] The details of the methodology used for sampling within the different project areas are described in section 4.1, *Ripogenus Project*, of the *Fish Assemblage Study Report* [Appendix D of the ISR].

(2015),[24] including raft electrofishing, which was completed at four sites within the reach.[25]

As required by the SPD, GLHA compiled information from all fish assemblage studies previously conducted in the Penobscot Mills Project area and assessed gaps in the fisheries information.[26] Fish assemblage data were also obtained from boat electrofishing surveys conducted as a part of the upstream American eel study conducted between June and October 2022 at the East Millinocket Development, which included bycatch data for other species.

Information collected in 2022 demonstrates project waters support a diverse fisheries community. A total of 23 fish species were collected from Ripogenus Project waters and 25 species were confirmed to occur in Penobscot Mills Project waters. The fish assemblage included a variety of game and non-game species, many of which are indigenous to the area,[27] including native minnows and sunfishes. Landlocked salmon, the principal sport fish species managed by Maine DIFW, were found to be throughout the Ripogenus and Penobscot Mills Project waters. The salmon population in the North Twin impoundment was found to be self-supporting.

As part of the study, GLHA compared historical fish species data for the Ripogenus impoundment with the 2022 survey results. Historical sampling identified a total of 20 fish species, 13 of which were collected during the 2022 sampling. Fish species historically detected in the Ripogenus Project area but absent from the 2022 Ripogenus impoundment catch included lake trout, lake whitefish, American eel, longnose sucker, blacknose dace, creek chub, and ninespine stickleback.

---

[24] Yoder *et al*. (2015) describes methods and designs for assessing fish assemblages in non-wadable rivers in New England.

[25] The sites included: within and downstream from Big Eddy, a previous Index of Biotic Integrity (IBI) site; immediately downstream from Little A Falls; the upper section of the Nesowadnehunk "deadwater;" and immediately downstream from Nesowadnehunk Falls, a previous IBI site.

[26] Historical, unpublished fish species inventory data were compiled from water bodies within the project area. Data from catches summarized in Midwest Biodiversity Institute (2005) were reviewed and summarized. Historical stocking data were summarized by year, waterbody, and species to describe game fish stocking patterns.

[27] Indigenous fish species known from the region include brook trout, American eel, yellow perch, white sucker, rainbow smelt, longnose sucker, lake whitefish, lake chub, golden shiner, fall fish, creek chub, common shiner, slimy sculpin, burbot, brown bullhead, and blacknose dace.

Requested Study Modifications

In his comments, Edward Spear claims that the *Fish Assemblage Study* does not accomplish agency and stakeholder goals. Mr. Spear also claims that there are major omissions in the study report, which he asserts are the result of a flawed study design or limitation of sampling gear. The major omissions cited by Mr. Spear include: (1) scale samples; (2) spring sampling; (3) smelt abundance data; (4) salmon or smelt length distributions;[28] (5) redd[29] surveys or dietary information collected for landlocked salmon; and (6) sampling in the West Branch downstream from North Twin Dam. In addition, Mr. Spear states that both boat electrofishing and trap netting are "shallow" water sampling methods and, thus are "biased." According to Mr. Spear, sampling with these methods cannot be used to describe or quantify the Ripogenus impoundment's fish community. Mr. Spear requests that GLHA revise the *Fish Assemblage Study Report* to address his concerns.

In its comments, Maine TU states that the study uses data collected in 2003, which is 20 years old, and asserts that new data is needed to confirm the presence of native fish. Maine TU also states that scale samples and fish metrics were not obtained. Maine TU, however, does not request specific modifications to the approved *Fish Assemblage Study*.

In its comments, Maine DIFW states that the results of the *Fish Assemblage Study* were as expected. The fish species identified by GLHA in the Ripogenus impoundment and the West Branch downstream from Ripogenus Dam are consistent with Maine DIFW's species inventory for these waters and are typical of waters in the region. Maine DIFW indicates that, based on its understanding, the study was intended to only identify species and not provide any indices of abundance, as this would be impossible given the size of the lake, and the various species and life histories involved.

Comments on Requested Study Modifications

In its reply comments, GLHA asserts that the study's design was not flawed. GLHA states that fish assemblage data were collected in 2022 for the Ripogenus impoundment and the West Branch downstream from McKay Station, and that the data were compared to data collected by the Midwest Biodiversity Institute in 2004 and 2009 to determine if any major changes in the fish assemblage had occurred during that 20-year period. GLHA states that the results of the sampling provide updated information on the fish assemblage at the Ripogenus Project, which GLHA asserts was the primary purpose of the study at the project. GLHA also states that the fish sampling relied on

[28] GLHA provided length distribution graphs for landlocked salmon collected during the Ripogenus Project sampling. *See* ISR, Appendix B-Attachment 3.

[29] A redd is a depression created by the female salmon for laying eggs.

traditional fisheries sampling techniques (e.g., electrofishing methods used in the West Branch followed that described in Yoder *et al*. (2015)). Moreover, GLHA states that sampling methods and locations were selected in consultation with Maine DIFW, the U.S. Fish and Wildlife Service (FWS), and Maine TU. Finally, GLHA asserts that the intent of the *Fish Assemblage Study* for the Ripogenus Project was to document the current fish community in the project area, not to collect: (1) information on the West Branch fisheries, landlocked salmon spawning, or salmon diets; or (2) data to derive age and growth statistics on fish populations (i.e., collecting scale samples), estimate smelt abundance, or estimate biomass and population numbers within the study area. GLHA concludes that the goals of the study for the Ripogenus Project were met.

Regarding spring sampling, GLHA states that based on the timing of when the SPD was issued, spring surveys could not be completed. GLHA notes that "the need for spring or late fall sampling is driven primarily by the spring migration of adult anadromous[[30]] species, such as river herring, and the outmigration of young-of-the-year anadromous fish in the fall." GLHA asserts that, since anadromous fish are not present in the West Branch, summer and early-fall sampling is sufficient to characterize the fish assemblage in the West Branch, and claims that a spring survey would not provide new or unique information.

Discussion and Recommendation

A goal of the *Fish Assemblage Study* was to characterize the fish community within the Ripogenus Project area. The *Fish Assemblage Study Report* provides a desktop review of historical fishery information from the project area (including unpublished data collected by Maine DIFW; e.g., smelt drift data), as well as information based on data collected during 2022 fish surveys.

The *Fish Assemblage Study Report* (*see* section 5.0, *Results*, in Appendix D of the ISR) provides Ripogenus Project area fish community information on: (1) the fish community (presence, absence, and distribution) in the Ripogenus impoundment and the West Branch downstream from Ripogenus Dam; (2) habitat and water quality at the sampling locations; (3) species richness, by season, sampling gear type, and sampling location; (4) species composition (number and percent), by season, sampling gear type, and sampling location; (5) relative abundance (catch per unit effort), by season and sampling gear type; (6) biometrics information (length and weight) for fish species

[30] The term "anadromous" refers to a life history strategy of fishes where fish migrate between fresh- and salt-water. Reproduction occurs in freshwater and rearing to the adult stage occurs in the ocean.

captured; (7) the condition of landlocked salmon (as measured by Fulton's K Factor[31]) and brook trout; (8) length frequency distributions for several fish species;[32] and (9) fish assemblage condition metrics, as measured by Index of Biotic Integrity and Diadromous Index of Biotic Integrity scores, for the West Branch downstream from McKay Station. Thus, the information in the *Fish Assemblage Study Report* provides updated information on the fish community at the Ripogenus Project, which meets the goal of characterizing the fish community within the Ripogenus Project area [section 5.9(b)(1)].

The SPD required fish sampling in the spring, summer, and fall. The intent of sampling in the spring was not to collect information on migrating anadromous fish, but rather collect information on resident species in the system during one of the most biologically active times of the year. While sampling in the summer and early fall provides useful information to characterize the fish assemblage within the Ripogenus impoundment and the West Branch downstream from Ripogenus Dam, it is not sufficient to determine the fish community structure in the spring and to fully characterize the fish assemblage at the project [section 5.9(b)(6)]. Sampling in the summer and fall, only, does not provide data for the spring spawning period and misses sampling the species active at that time (e.g., smelt).[33] Without fish assemblage information for the spring season, Commission staff will be unable to complete a full NEPA review of potential project effects and make recommendations regarding license requirements [section 5.9(b)(5)]. For these reasons, we recommend GLHA complete the *Fish Assemblage Study* as required in the SPD and conducted spring sampling in 2024. This includes sampling in the Ripogenus impoundment, Upper Gorge, and the West Branch downstream from McKay Station, at sampling locations determined in consultation with Maine DIFW and Maine TU.

Mr. Spear and Maine TU assert that the study design is flawed because various types of information are missing from the report, and that the report is biased as a result and cannot be relied upon for making decisions in the current relicensing proceeding. The approved *Fish Assemblage Study* was not designed to collect the types of information that Mr. Spear and Maine TU state is missing. For example, the approved

[31] Fultin's K Factor is a measure of a fish's condition. It is the weight of a fish divided by the length cubed, then multiplied by 100. The higher the number, the better a fish's condition. The number 1 indicates a "normal" fish in "ok" condition.

[32] Length distribution data for landlocked salmon collected, as well as captured by anglers, downstream from McKay Station in 2021 and 2022 is provided in the ISR (*see* Appendix B, Attachment 3).

[33] Other spring/early summer spawners that occur in project waters include white and yellow perch, brown bullhead, white and longnose sucker, blacknose dace, and slimy sculpin.

study did not require: (1) smelt surveys;[34] (2) the collection of scales for age and growth analysis;[35] (3) salmon dietary information;[36] (4) calculation of proportional stock densities; (5) salmon redd surveys; or (6) an assessment of the status of the sport fishery in the area. Thus, the report is not flawed due to omissions. The information in the *Fish Assemblage Study Report*, once completed (with spring sampling at the Ripogenus Project), will be sufficient to inform a licensing decision for the projects [section 5.9(b)(5)]. Moreover, no new information has come to light that supports the need to collect the requested information [section 5.15(e)(4)]. Therefore, we do not recommend, apart from the spring sampling, that GLHA collect the requested information.

With respect to Maine TU's request for new, fresh information to confirm the presence of native fish, the approved *Fish Assemblage Study* included fish and aquatic surveys in the Ripogenus impoundment and in the West Branch downstream from McKay Station. For the Ripogenus Project, the *Fish Assemblage Study Report* documented this sampling effort, including noting the presence of a mix of 23 native and non-native species at the project. The report also included a comparison between 2022 and 2004/2009 surveys, which showed that: (1) the fish assemblage in the Ripogenus Project area has changed little over the 20 year period; and (2) the ecological health of the river scores (derived from the New England Large Rivers IBI model) are consistent between the two surveys. As stated above, the information in the *Fish Assemblage Study Report*, along with the additional sampling required in this determination, will be sufficient to characterize the fish community in the project area [section 5.9(b)(4)]. Therefore, updated information to confirm the presence of native fish is not needed.

For the Penobscot Mills Project area, the SPD did not require surveys. Instead, it anticipated that, if existing information proved insufficient for achieving the goal of describing the current fishery, and important data gaps in the fisheries information remained, additional studies to obtain that information could be considered after filing of the ISR. Based on our review of the ISR (described above), the information in the *Fish Assemblage Study* is sufficient to describe the existing fishery in the Penobscot Mills

[34] Maine DIFW conducted a smelt drift survey in the West Branch downstream from McKay Station in 2021, and this information was included in the *Fish Assemblage Study Report*. Maine DIFW also conducted smelt drift work in 2022. While the 2022 data may be currently unavailable, it should be included in an updated *Fish Assemblage Study Report* filed as part of the USR. Available smelt drift data were provided in table 5, page D-45 of the ISR (Appendix D).

[35] Biometric age and growth information for salmonids in the Ripogenus impoundment was provided by Maine DIFW and is included in the ISR (Appendix D, page D-43).

[36] Maine DIFW provided stomach content analysis to GLHA, which is provided on page D-43 (Appendix D) of the ISR.

Project area [section 5.9(b)(4)]. Therefore, we do not recommend modifying the approved *Fish Assemblage Study* to require field sampling within the Penobscot Mills Project area.

**6. Instream Flow and Habitat Assessment of the West Branch Downstream from Stone Dam Study**

Background

The SPD required GLHA to conduct an *Instream Flow and Habitat Assessment of the West Branch Downstream from Stone Dam Study*. The goal of the study was to assess the relationship between flow and aquatic habitat in the West Branch downstream from Stone Dam using a previously developed Physical Habitat Simulation (PHABSIM) model. The specific objectives were to: (1) assess the relationship between flow and aquatic habitat for brook trout, landlocked salmon, and aquatic macroinvertebrates in the study reach; (2) assess the potential of the current project operating regime and minimum flows to support a coldwater fishery between Stone Dam and Grand Falls, which is a natural falls located about 2.7 miles downstream from the dam; and (3) evaluate the potential for alternative minimum flows in the reach to support a seasonal, coldwater sport fishery.[37]

The study applied updated habitat suitability criteria (HSC)[38] reflecting contemporary resource management objectives.[39] Modeling was conducted using standard procedures described by Bovee (1982) and Bovee, *et al*. (1998).[40] The basic inputs to PHABSIM are the hydraulic and habitat suitability simulations of stream reaches using hydraulic parameters and habitat suitability criteria. The result is a quantitative habitat suitability index (summarized as weighted usable area, or WUA) that is derived by rating the hydraulics using HSC for the variables of depth, velocity, and substrate/cover specific to each species of interest. The flows modeled ranged from 3 cfs to 2,000 cfs. GLHA conducted site visits in August 2022 with personnel from Maine

[37] Habitat upstream of Grand Falls is dominated by riffles and runs with scattered braided channels, with predominantly boulder substrate.

[38] Habitat suitability criteria are selected prior to conducting modeling.

[39] GLHA consulted with Maine DIFW and Maine DEP staff to finalize the HSC for adult brook trout and macroinvertebrates prior to conducting modeling. Maine DIFW concluded that the HSC for landlocked salmon used in the original model were still valid for use in the 2022 study.

[40] Additional details regarding the IFIM modeling approach are described in section 4.0, *Methodology*, of the *Instream Flow and Habitat Assessment of the West Branch Downstream from Stone Dam Study Report* (Appendix F of the ISR).

DIFW, Maine DEP, FWS, the National Marine Fisheries Service, the Maine Department of Marine Resources (Maine DMR) and the Penobscot Indian Nation. The group examined the study area, discussed the existing PHABSIM model, and confirmed that the previous Instream Flow Incremental Methodology (IFIM) study sites were suitable for purposes of this updated study.

The results and conclusions of the 2022 flow study are:

(1) Based on brook trout temperature tolerances, flows with water temperatures that support a put-and-take coldwater fisheries (especially for brook trout) would likely occur from April into July. Flow during the remainder of the year would support habitat for macroinvertebrates.

(2) A leakage[41] flow of 50 cfs provides 34%, 40%, and 57% of the maximum potential habitat suitability[42] for macroinvertebrates, adult brook trout, and juvenile brook trout, respectively; and 59% and 15% of the maximum habitat suitability for juvenile and adult landlocked salmon, respectively.

(3) A leakage flow of 100 cfs provides 45%, 49%, and 64% of the maximum potential habitat suitability for macroinvertebrates, adult brook trout, and juvenile brook trout, respectively; and 70% and 28% of the maximum habitat suitability for juvenile and adult landlocked salmon, respectively.

(4) The range of existing operational flows, when accounting for spill flows at Stone Dam,[43] provides at least 40% to 64% of the maximum suitable habitat for brook trout, and 15% to 70% of the maximum suitable habitat for salmon, with periodically higher suitability due to spill flows.

(5) The modeling estimates that the best habitat suitability for adult brook trout and landlocked salmon occurs with minimum flows between 700 cfs and 1,000 cfs.

---

[41] Leakage from Stone Dam can vary depending on the seasonal impact of flows and ice on the flashboards, as well as short-term wind/wave action, and has been estimated to vary from 3 cfs to 100 cfs.

[42] The term "maximum habitat suitability" is used here merely as a reference point to relate how various flows effect habitat and not as a metric. Fishability (i.e., the ability for anglers to be able to safely wade and reach game fish lies within casting distance) may be more relevant than maximizing habitat suitability.

[43] GLHA does not define in the study report what is meant by operational flows in the context of Stone Dam operations. Based on the operations data filed by GLHA on May 22, 2023, the range of flows spilled at Stone Dam (defined as non-operational flows), from 2000 to 2022, was 17 cfs to 24,235 cfs.

Requested Study Modifications

In his comments, Edward Spear argues that the flow study fails to meet the study goal of assessing the relationship between flow and aquatic habitat in the West Branch downstream from Stone Dam. Mr. Spear asserts that the HSC for brook trout need to be revisited and either empirically derived or taken from peer reviewed literature. Mr. Spear states that the HSC for adult brook trout used in the flow study are unsuitable for a large, wide riverine environment like the West Branch downstream from Stone Dam. Mr. Spear recommends the use of HSC developed for the Dead River (Flagstaff Storage Project No. 2615). Mr. Spear also asserts that the study report fails to address where and how anglers would locate a place to fish and recommends that the study (and associated report) be updated to include pools and deep runs where anglers would choose to fish.

In its comments, Maine TU references a "persistent habitat analysis" conducted by FirstLight for the Turners Falls Project No. 1889 on the Connecticut River in Massachusetts. Maine TU states that a similar analysis would be reasonable for the West Branch downstream from Stone Dam.

Comments on Requested Study Modifications

In its reply comments, GLHA states that the HSC used in the study were developed according to IFIM study protocols, and Maine DIFW and Maine DEP were consulted for input on the HSC used, prior to the model being finalized. GLHA indicates that Maine DIFW biologists applied professional judgment, relying on department brook trout experts, to arrive at the HSC used in the study, and that the curves were recommended by Maine DIFW biologists.

Regarding Maine TU's request for a "persistent habitat analysis," GLHA states that such analysis is not appropriate for the river reach downstream from the Millinocket Development. GLHA indicates that such an analysis is done for river reaches downstream from peaking facilities, rather than run-of-river facilities like the Millinocket Development.[44] GLHA further explains that the method evaluates generation flows versus base flows, with the intent of altering peaking operations to optimize habitat suitability.

Discussion and Recommendation

The goal of the 2022 flow study was to assess the relationship between flow and aquatic habitat in the West Branch downstream from Stone Dam using an updated

[44] Typical impoundment elevation fluctuations are limited to 1 foot or less from top of flashboards when installed or crest of dam without flashboards.

version of the 1989 IFIM model. As part of the approved study, GLHA was to consult with Maine DIFW, Maine DEP, and other interested stakeholders for input on HSC criteria. GLHA carried out this consultation. Candidate curves obtained and reviewed by a team of stakeholder biologists were gathered from large river IFIM studies, including those conducted on the Allagash and Magalloway Rivers. The study report includes the results of the modeling, including: (1) descriptions of the reach hydraulics (e.g., depth, velocity, and wetted area) under different flows; and (2) data in graphic and tabular form depicting flow/habitat relationships for the species and life stages of brook trout and landlocked salmon, and for macroinvertebrates. The study report also includes a discussion of: (1) seasonal suitability of the reach for a managed (put-and-take) salmonid fishery; (2) the effects of existing, year-round project operation on fish and macroinvertebrates; and (3) potential for alternative minimum flows in the reach. Thus, the flow study conducted in 2022 meets the study's goals and objectives described in the SPD [section 5.9(b)(1)].

Regarding Mr. Spear's assertion concerning the origin and appropriateness of the HSC rating curves used for brook trout, GLHA consulted with Maine DIFW and Maine DEP to finalize the HSC for brook trout and macroinvertebrates prior to conducting the modeling. HSC from IFIM studies conducted in Maine, Connecticut, Massachusetts, New York, Pennsylvania, and Michigan were considered. Moreover, through consultation with the agencies, it was determined that the study area on the West Branch is composed of riffles, runs, and pocket pools with poor cover, and dominated by boulder and some large cobble substrates. Therefore, the HSC used in the modeling for the West Branch were appropriate. Using the HSC from the Dead River (a tributary to the Kennebec River in Maine), as suggested by Mr. Spear, is unnecessary and would not likely alter the results of the flow study which used appropriate HSC [section 5.9(b)(6)]. Therefore, we do not recommend modifying the study design to use the HSC from the Dead River.

As to Mr. Spear's recommendation to include, as part of the assessment, pools and deep runs where anglers would choose to fish, the 2022 IFIM study used the model developed in 1989 and included two study sites with 13 transects. The two study sites were chosen to represent the dominant habitat types in the upper and lower sections of the 2.7-mile-long study reach. Habitat types in this reach are dominated by riffles and runs with scattered braided channels, with predominantly boulder substrates.[45] The 2022

[45] The upper portion of the West Branch downstream from Stone Dam (location of study site 2) is wider and of lower gradient than the lower portion (location of study site 1) and occupies 10,692 liner feet of the channel (Normandeau Associates, 1989). The geomorphology in this portion of the West Branch is chiefly alluvial with a few scattered bedrock-controlled areas. The lower reach is narrower, steeper and has a better-

study built upon those widely accepted protocols (e.g., Bovee, 1982; Bovee et al., 1998) [section 5.9(b)(6)]. Because pools and deep runs are not the dominant habitat types in the reach and using non-dominant habitat types would run counter to the accepted protocols, we do not recommend that GLHA modify the study design to include pools and deep runs where anglers would choose to fish.

Finally, regarding Maine TU's request for a "persistent habitat analysis," or habitat duration analysis, such an analysis is typically done in reaches downstream from peaking projects to evaluate how long a given amount of habitat is available for use by aquatic organisms at particular flows. Stone Dam is not operated in this fashion. Instead, flows exceeding the project's generation capacity are spilled to maintain impoundment elevations at a relatively constant level. These are not controlled generation releases, as would be the case with a peaking project. Even if this reach of the West Branch had an established minimum flow, flows in excess of the Millinocket powerhouse's capacity would continue to spill over the Stone Dam spillway and GLHA would continue to have no control over frequency or magnitude of these spill flows [section 5.9(b)(5)]. For this reason, we do not recommend modifying the flow study to include a "persistent habitat analysis."

**7. North Twin Impoundment Tributary Access Survey Study**

Background

The SPD required GLHA to conduct a *North Twin Impoundment Tributary Access Survey*. The goals of the survey were to assess connectivity and spawning conditions for landlocked salmon in tributaries to the North Twin impoundment, as well as determine if there are barriers to fish movement into the tributaries during drawdowns of the North Twin impoundment. The specific objectives were to: (1) identify tributaries to the North Twin impoundment that are used by landlocked salmon for spawning or that have habitat suitable for spawning; (2) survey the identified tributary streams and identify potential fish passage barriers both natural and project-related near their confluence with the North Twin impoundment; (3) document evidence of spawning (e.g., spawning behavior and redd formation); and (4) evaluate the effects of the typical seasonal impoundment fluctuation on tributary access by landlocked salmon during critical life stage(s). The study area included eight tributaries to the North Twin impoundment.

Reconnaissance surveys of the West Branch upstream of Ambajejus Lake, Nahmakanta Stream, Partridge Brook, Jo Mary Stream, Twitchell Brook, Wadleigh Stream, Ragged Brook, and an unnamed brook on the southern shoreline of North Twin

---

defined channel and occupies 3,564 linear feet of the channel (Normandeau Associates, 1989). The substrate in both reaches is predominantly large boulders.

Lake (a sub-basin of the North Twin impoundment) were made in July 2022, when North Twin impoundment water levels were at a typical summer level. Photographs of each tributary were taken to characterize each site. Points of interest were georeferenced with a hand-held Global Positioning System (GPS) unit. The mouths of the tributaries were: (1) assessed for potential barriers to adult landlocked salmon movement (e.g., ledge drops, debris jams, and wide shallow channel reaches); and (2) surveyed (by optical transit level) to obtain channel slope and width.

Based on consultation with Maine DIFW, the West Branch at Ambajejus Falls,[46] Nahmakanta Stream, and Jo Mary Stream were identified for further survey work. These three tributaries were to be assessed and re-surveyed during the fall spawning period under seasonal drawdown conditions. GLHA was to examine the area immediately above the high-water mark in each tributary[47] and the shoal area for potential spawning habitat and/or evidence of redd construction in 2022.[48]

Requested Study Modifications

In its comments, Maine DIFW states that field conditions were unsuitable in fall 2022 for completing the tributary surveys, as planned, due to extended rainfall in October and November 2022, and that GLHA anticipates completing fieldwork in the fall of 2023.[49]

Comments on Requested Study Modifications

In its reply comments, GLHA states that it is intending to complete the approved *North Twin Tributary Access Survey* in 2023. Regarding the scope of the partially completed *North Twin Tributary Access Survey*, GLHA clarifies that, in addition to evaluating potential tributary barriers, GLHA intends to survey bed elevations in coves

[46] Ambajejus Falls is a riffle/rapid complex located at the confluence of the West Branch. Ambajejus Lake is a sub-basin of the North Twin impoundment.

[47] The SPD required that GLHA examine the tributaries immediately above the North Twin impoundment's high-water elevation for a horizontal distance upstream in the tributary of 100 meters (i.e., 328 feet).

[48] Efforts were made to schedule the fall surveys for the three identified tributaries during October and early November of 2022. Due to high inflows, typical fall drawdown levels for the North Twin impoundment were not achieved and it was not possible to conduct the additional stream channel survey work during the fall 2022.

[49] Maine DIFW, Maine TU, and Mr. Spear also repeated requests for an alternative methodology utilizing radio tagging, which we addressed in the May 13, 2022, SPD. As noted in the cover letter, we do not repeat that analysis here.

adjacent to the targeted tributaries to determine if they could become dewatered under the potential range of seasonal drawdowns. GLHA would attempt to identify potential shoal areas in coves in the North Twin impoundment that have substrates suitable for redd formation (e.g., gravel) adjacent to Nahmakanta and Jo-Mary streams, as well as the West Branch through soundings or other means. GLHA would consult with Maine DIFW concerning the location of specific offshore spawning shoals that should be targeted. GLHA would then determine the elevation of these beds to determine if the identified areas become unsuitably shallow during fall drawdowns, over the salmon spawning and incubation period, as a function of project operation.

Discussion and Recommendation

The *North Twin Impoundment Tributary Access Survey Study* was conducted as provided for in the SPD; though the study occurred during anomalous environmental conditions [section 5.15(d)(2)]. The combination of atypical, high impoundment levels and high stream discharges created circumstances that prevented potential instream barriers from being adequately detected or surveyed. The protracted period of unseasonably warm weather also delayed and/or altered spawning behavior of salmon to the extent that it was not feasible to document evidence of spawning. Therefore, we recommend GLHA complete the *North Twin Tributary Access Survey* approved in the SPD in 2023, with GLHA's proposal, as described above, to evaluate shoal habitat in the North Twin impoundment. We also recommend GLHA consult with Maine DIFW in the final design and implementation on this study.

**8. Upstream American Eel Passage Assessment**

Background

In accordance with the SPD, GLHA conducted an *Upstream American Eel Passage Assessment* at the East Millinocket Development. The goals of the study were to: (1) assess whether eels are found in or near the East Millinocket tailwater area, congregate at or near the base of East Millinocket Dam, or attempt to migrate upstream over East Millinocket Dam; and (2) collect information about the timing of movements, behavior, and the approximate size of juvenile eels observed at the dam. GLHA also completed a pilot study, using eDNA techniques described by Chin *et al*. (2021),[50] to determine if it is feasible to use eDNA to assess the presence and relative distribution of eels in the West Branch. The study area for the assessment included East Millinocket

[50] Environmental DNA (eDNA) is organismal DNA that can be found in the environment. Environmental DNA originates from cellular material shed by organisms (via skin, excrement, etc.) into aquatic or terrestrial environments that can be sampled and monitored using new, molecular methods.

Dam and the tailwater area. For the eDNA study, the study area included select reaches of the West Branch (downstream from the East Millinocket Development), the lower East Branch of the Penobscot River, and the mainstem Penobscot River.

The survey methodology approved in the SPD included nighttime visual surveys (20 surveys from June 1 to October 17, 2022),[51] boat electrofishing surveys,[52] eel traps,[53] and eDNA techniques.[54] A total of 556 eels were observed during the nighttime visual surveys at East Millinocket Dam, and most (96 percent) were seen immediately downstream from an existing large, steel gate on the river left side (looking downstream) of the dam in July and August. Juvenile eels were able to ascend the dam face but appeared unable to readily pass through or under the steel gate. Data from monthly boat electrofishing surveys demonstrated that most small (4- to 8-inch) juvenile eels were present at the base of the dam, with the highest densities (95 percent) in June and July. No eels were collected in the eel traps. Finally, laboratory analysis of water samples for the eDNA study also showed that eels were present at all sampling locations, including at East Millinocket Dam, but no meaningful relationship between eDNA concentrations and eel density could be established.

In its comments on the ISR and the ISR Meeting Summary, Maine DMR commented on the study methodology and requested that additional information be provided in the study report. GLHA provided much of this information in its reply comments. In its comments, Maine TU commented on the significance of the number of juvenile eels observed and collected downstream from East Millinocket Dam. Neither

[51] Survey techniques included repeated visual, nighttime observations using binoculars and spotlights with infrared lighting to observe eels during non-spill conditions. Each survey lasted approximately 1 to 2 hours and took place after sunset between 6:30 p.m. and 11 p.m. Survey areas at East Millinocket Dam included the dam face, spill gates, wooden flashboard section of the spillway, and concrete piers, as well as the dam's right abutment area.

[52] Nightly boat electrofishing was completed immediately downstream from East Millinocket Dam, mostly in a large riverine pool downstream from the toe of the dam. Surveys were completed on June 29, July 20, August 24, September 21, and October 10, and occurred along shallow areas less than 6 feet deep, along the shoreline and near the base of the dam. Electrofishing survey time range from 27 to 52 minutes.

[53] Two eel traps were installed downstream from East Millinocket Dam on the left side of the river (looking downstream). The traps were deployed from June 28 through July 28, 2022, for 48 to 96 hours per week. Each trap consisted of a covered eel ramp with eel substrates, a collection trap, batteries, solar panels, and water pumps.

[54] Details of the survey methodology are provided in Appendix H of the ISR.

Maine DMR, nor Maine TU, however, requested specific modifications to the approved study.

Proposed Study Modifications

Based on the upstream eel monitoring results at the East Millinocket Development and discussions with Maine DMR, GLHA, in its reply comments, proposes to monitor juvenile eels at Dolby Dam, Millinocket Lake Storage Dam, Stone Dam, and North Twin Dam in 2023.[55] The goals of the modified study would be to: (1) obtain information about the presence of juvenile eels at the project dams; (2) observe and record if and where eels congregate, and if they attempt to migrate upstream at project features (e.g., face of dam, gates, etc.); (3) collect information on the size of the eels observed; and (4) use the data collected, in combination with that collected in 2022 at East Millinocket Dam, to consider potential measures to be included in a license application.

GLHA's proposed methodology would include nighttime visual surveys once a week, by foot, at each of the four dams, from July through the last week of September. The nighttime surveys would last about 1 to 2 hours at each site, starting just before or after sunset. Areas would be visually searched with binoculars and red spotlights. Survey time, weather conditions, general river flow conditions, presence and location of eels, size classes of eels, and observable migratory behavior (e.g., congregating or attempting to ascend structures) would be recorded. Surveys would be completed during non-spill conditions. In addition to the nighttime visual surveys, GLHA also proposes two nighttime backpack or boat electrofishing surveys downstream from each of the four dams in July, August, or September, if conditions are safe and sampling is feasible. Each survey would last about 20-30 minutes.

Comments on Proposed Study Modifications

In its comments, Maine TU states that it supports GLHA's proposal to conduct nighttime eel studies at the upstream Penobscot Mills dams in 2023.

Discussion and Recommendation

GLHA's *Upstream American Eel Passage Study* documented the presence of juvenile eels in the West Branch downstream from East Millinocket Dam. A total of 556

[55] GLHA developed a draft plan for monitoring juvenile eels at Dolby Dam, Millinocket Lake Storage Dam, Stone Dam, and North Twin Dam in 2023. This draft plan was sent to FWS, Maine DMR, and the Penobscot Indian Nation via email on June 2, 2023. FWS commented on the draft plan via email on June 15, 2023. GLHA addressed FWS's comments in the proposed plan.

eels were observed during the nighttime visual surveys;[56] 98% (545) of which were counted during the months of July (371), August (162), and September (12).[57] The remaining 11 eels were observed in June.

The results of the study indicated that considerably more eels are present in this part of the West Branch than previously documented [section 5.9(b)(4)]. More juvenile eels were observed during this study at East Millinocket Dam than have been documented passing the downstream Medway Dam. These results confirm that juvenile eels can pass in-river obstructions such as dams under the right conditions. Given the large number of eels observed ascending East Millinocket Dam, it seems likely that eels occur in the system upstream of the East Millinocket Development. Thus, monitoring eels at the remaining four dams that compose the Penobscot Mills Project is warranted. The outcome of such monitoring would help GLHA identify appropriate measures to enhance upstream eel passage at the project, as well as eel movement in the West Branch [section 5.9(b)(5)].

During the study, GLHA used boat electrofishing, trapping, and eDNA sampling, in addition to repeated nighttime visual surveys. As described in the ISR, trapping and eDNA sampling provided little, if any, additional information about the presence and behavior of eels at the East Millinocket Development [section 5.9(b)(7)]. For these reasons, GLHA is proposing to use nighttime visual surveys for the study, with some backpack/boat electrofishing (if conditions allow). Repeated nighttime surveys have been successful at several hydropower projects in Maine to document the presence and behavior of juvenile eels.[58] Moreover, Haro and Gephard (2023) state that the primary technique for observing eels at dams is nighttime observational surveys by foot. Thus, GLHA's proposed methodology is scientifically acceptable in the region, and is a locally demonstrated method of observing eels and should be sufficient to address the goals of the study without further need of trapping and eDNA sampling [section 5.9(b)(6)].

GLHA proposes to monitor eels during the months of July, August, and September 2023. For the 2022 study at East Millinocket Dam, nearly all the juvenile eels observed during the nighttime visual surveys (98%) and caught during the boat electrofishing

---

[56] A total of 153 eels (nearly 45% of the total species caught) were caught during the boat electrofishing surveys.

[57] Though required by the SPD, May was not sampled due to high flows and unsafe conditions at the East Millinocket Dam site.

[58] Nighttime visual surveys have been successfully used at the Williams, West Enfield, Stillwater, Orono, Milford, Lowell Tannery, Lower Barker, and American Tissue Hydropower Projects in recent years to provide information about the occurrence and behavior of juvenile eels in Maine rivers. *See* GLHA's August 7, 2023 Filing at Appendix F-1.

efforts (99%) were in the months of July (including a June 29 sampling event), August, and September. It is reasonable to expect that upstream passage timing would be similar at the upstream dams. Therefore, the sampling season proposed by GHLA would likely capture the majority of upstream juvenile eel movement in the West Branch, without the expense of requiring GLHA to sample in the months when upstream eel migration is less likely [section 5.9(b)(7)].

For the above reasons, we recommend that the *Upstream American Eel Passage Assessment* be modified to include a second study season of eel monitoring in 2023, as proposed by GLHA, at Dolby Dam, Millinocket Lake Storage Dam, Stone Dam, and North Twin Dam. We specifically recommend that GLHA add sampling at the four dams upstream of East Millinocket Dam, follow the methods discussed above, and consult with FWS, Maine DMR, and the Penobscot Indian Nation in implementing the study. The results of this eel monitoring should be included in a final *Upstream American Eel Passage Assessment Report* provided with the USR.

**15. Common Loon Management Plan Assessment**

Background

The SPD required GLHA to evaluate information collected over the term of the current license related to common loons at the Ripogenus impoundment, including information on how the loon management plan for the project has been implemented. The assessment considered: (1) the results of the 1998 and 1999 spring and summer loon survey; (2) the results of the 2000-2010 annual loon artificial nest and natural nest monitoring, including, to the extent the information was available, where the artificial rafts were deployed; (3) procedures used to deploy and maintain the artificial nests from 2011 to 2021; and (4) an evaluation of the artificial nest locations in relation to bathymetry maps and historic impoundment elevation data. Information from the study would be used to inform a decision on the need for measures for common loons at the Ripogenus Project.

Requested Study Modification

In his comments, Edward Spear asserts that GLHA did not conduct loon surveys on the West Branch downstream from McKay Station. Mr. Spear states that a pair of loons is currently nesting in Neoowadnehunk Deadwater, although the location of the nest is unknown. He requests no specific modifications to the approved loon study, but states that GLHA should include the West Branch reaches downstream from McKay Station in all future loon surveys and evaluate the effects of up and down peaking flows on nesting success.

Comments on Requested Study Modifications

GLHA did not comment on Mr. Spear's recommendation regarding future loon surveys.

Discussion and Recommendation

The results from GLHA's *Common Loon Management Plan Assessment* indicate that the nest platforms were either not used, or loons using the platforms had limited or no reproductive success over the duration of the monitoring from 2000 to 2010. GLHA indicates that numerous factors contributed to failed nesting and lack of chick success, including fluctuations in the impoundment elevation (both increases and decreases in water levels), predation of eggs or chicks, and abandonment of the nest for unknown reasons. The Caribou and Chesuncook Lake Camp Association, Chesuncook Village Association, and the Chesuncook Dam Camp Association (collectively, Camp Associations) commented that that the results of the loon assessment study are a clear example of the effects of littoral zone exposure and severe drawdowns.

GLHA's *Common Loon Management Plan Assessment* met the SPD's goals and objectives [section 5.9(b)(1)]. The management area encompasses the Ripogenus impoundment, which is subjected to impoundment level fluctuations from project operation that can vary from year to year and are dependent upon the timing of the spring freshet, as well as the release of flows to meet downstream flow requirements. The assessment report also provided information on how the current loon management program at the project is being implemented. As noted above, information from this report will be used to assess and make recommendations for loon management at the Ripogenus Project over the term of a new license [section 5.9(b)(5)]. Thus, we do not recommend Mr. Spear's requested modifications to the approved *Common Loon Management Plan Assessment*.

**16. Recreation Study**

Background

The SPD required GLHA to conduct a *Recreation Study*, under which GLHA was to: (1) inventory and map existing Commission-approved project recreation sites, including locations, facilities and amenities, general site conditions, ownership, and management responsibilities; (2) evaluate recreation use at project recreation sites, including both an assessment of the amount of recreation use that each site receives and the recreation activities that occur at the site for both the summer and winter recreation seasons; (3) conduct user surveys at the project recreation sites, and online, to assess activities (including angling), site conditions, satisfaction with existing facilities, and recommendations regarding the sites and facilities; (4) conduct qualitative interviews or focus groups to obtain information on the informal and formal recreation sites; and (5)

assess the accessibility and useability of select project boat launching facilities provided at the project recreation sites (i.e., Chesuncook Dam Point Boat Launch, Caribou Lake Put-In, Millinocket Lake Boat Launch, Ambajejus Lake Boat Launch, and South Twin Lake Boat Launch) over the range of drawdown conditions experienced under existing project operations, and report on any changes that would be needed at the boat launching facilities to make them useable under the range of expected recreation season water levels.

Requested Study Modifications

In its comments, AW/AMC states that neither the user interviews nor the focus groups were conducted and were not reported as a variance from the approved *Recreation Study Plan*. AW/AMC also states that there are issues with access to certain informal recreation areas, such as trails leading to the water downstream from Ripogenus Dam, and requests that the *Recreation Study* include informal recreation access areas identified by stakeholders. Finally, AW/AMC indicates that a low number (34) of surveys were completed at the Penobscot Mills Project recreation sites and requests an additional study season to collect additional surveys.

The Camp Associations request that the *Recreation Study* include interviews with a variety of organizations, to possibly include the Camp Associations, commercial interests, and commercial river guides. The Camp Associations are also concerned about data discrepancies, which they state could be due to the use of the QR-code enabled Recreation Survey questionnaires, and request that alternative data, such as pictures and spot counts from people on site be accepted. Finally, the Camp Associations request that recreation use on Chesuncook, Caribou and Ripogenus Lakes be documented through the winter recreation season (January through March).

The Maine Bureau of Parks and Lands (Maine BPL) comments on the low number of surveys collected for the projects, and requests that: (1) GLHA conduct a fall and winter study during the second study season; and (2) in-person surveying replace or supplement the use of kiosks and online surveying to obtain more representative data. Maine BPL recommends that interviews or focus groups, as required in the SPD be part of the year two recreation studies. Finally, Maine BPL requests that the *Recreation Study* be modified to include an evaluation of recreation access to the West Branch downstream from Stone Dam, and a potential portage around Great Falls.

In his comments, Christopher Howe requests that the *Recreation Study* be amended to include all formal and informal access sites from Ripogenus Dam to the Grant Brook Road Bridge.[59] In its comments, Maine TU comments on the low numbers

[59] A distance of approximately 20 river miles downstream from the dam.

of completed survey forms for the projects and that there is a need for interviewers in the field. Maine TU also comments that the study needs to reflect the recreation season, which extends through September, and that the fishing survey numbers are inadequate to assess use. Finally, in its comments, the Maine Professional Rafting Outfitters (Maine PRO) recommends a *Recreation Access Study* only if the *Whitewater Study* is not amended.

Comments on Requested Study Modifications

In its reply comments, GLHA proposes to conduct a year two recreation study in 2023 to address stakeholder comments and to complete remaining tasks from the year one study. The study would include: (1) the completion of the planned inventory, use counts, and user surveys at the Green Bridge Boat Launch; (2) the completion of the inventory at the Dolby Pond and Dead Man's Curve Boat Launches; and (3) the collection of additional spot and calibration count data at the Dolby Pond and Dead Man's Curve Boat Launches. Also, GLHA would redeploy the user survey boxes at all project recreation sites in late July 2023 and leave them in place through March 2024. Further, GLHA proposes to convene a recreation focus group to: (1) review the information collected as part of the 2022 study; (2) obtain additional information on the project recreation sites; and (3) identify and evaluate key informal non-project recreation sites that provide important public access to project waters.

Discussion and Recommendation

GLHA's proposal to convene a focus group would provide a mechanism to collect additional information on formal and informal recreation sites at the projects [section 5.9(b)(4)]. While one focus group session would be helpful, we recommend that GLHA, as part of the 2023 *Recreation Study*, convene two focus group sessions, in order to both present data to the focus group participants and collect sufficient information from them [section 5.9(b)(6)]. The focus groups would be able to consider and comment on data discrepancies in the kiosk data. Addressing recreation access issues would be part of this process.

Regarding the requests for additional recreation surveys and in-person surveys, GLHA has redeployed their survey kiosks, allowing them to capture recreation data from the summer and winter recreation seasons. This should allow for more recreationists to be surveyed than in-person surveying, due to the remote and large nature of the projects [section 5.9(b)(7). Moreover, the combination of focus group sessions and the redeployment of the survey kiosks would provide for thorough locational and topical coverage of regarding recreation use input [section 5.9(b)(6)]. Because of the cost involved with in-person surveys at such remote and large-scale projects, the proposal for focus group sessions and the redeployment of the survey kiosks with more defined

instructions seems to be a reasonable compromise. Therefore, we do not recommend that the *Recreation Study* be modified to include additional in-person surveys.

**17. Whitewater Boating Assessment**

Background

The SPD required that GLHA conduct a *Whitewater Boating Assessment*, equivalent to a Whittaker Level 1 study,[60] using a combination of a literature review, a survey of whitewater boaters, and hydrologic analyses for four study reaches associated with the projects: (1) West Branch downstream from McKay Station to Debsconeag Falls; (2) West Branch downstream from Ripogenus Dam to McKay Station ("Upper Gorge" or "dryway"); (3) West Branch downstream from Stone Dam to Shad Pond; and (4) Millinocket Stream downstream from Millinocket Lake Storage Dam. The SPD also indicated that, depending on the findings of the first study season, a Level 2 or Level 3 study may be needed. GLHA conducted the *Whitewater Boating Assessment* on each of the four study reaches, in 2022.

Requested Study Modifications

TU comments that Level 2/3 studies may be needed in the Upper Gorge and that Level 2/3 studies are needed on the West Branch downstream from Stone Dam. Maine TU suggests that the studies be combined with wadability/fishability studies. Maine TU notes that access to the river on the West Branch downstream from Stone Dam is blocked by a locked gate and that boaters must paddle or row about 1 mile to reach Stone Dam.

In its comments, Maine BPL recommends a Level 2 or Level 3 study in the West Branch downstream from Stone Dam, conducted in consultation with American Whitewater and other paddling interests. Maine PRO recommends either amending the existing *Whitewater Study* (to evaluate the need for additional whitewater boating opportunities at the projects) or a *Supplemental Access Study* (to explore ways to improve and expand access to the West Branch and Millinocket Stream), but not to both. Cristopher Howe requested Level 2/3 whitewater boating studies for Millinocket Stream, the Upper Gorge, and the West Branch downstream from Stone Dam, as well as study of access issues to the West Branch downstream from Stone Dam. Finally, in its comments, AW/AMC requests that GLHA conduct Whittaker Level 2/3 studies, of the Upper Gorge

[60] Whittaker, *et al*. (2005) provides a generally accepted whitewater boating methodology that involves a phased approach consisting of three progressive levels: (1) a Level 1 desktop analysis; (2) a Level 2 on-land feasibility assessment and/or on-water single-flow feasibility assessment; and (3) a Level 3 intensive study, including multiple flows.

and West Branch downstream from Stone Dam reaches, and analyze how to improve access on these reaches, due to insufficient information gained from the Level 1 studies.

Comments on Requested Study Modifications

In its reply comments, GLHA states that it does not propose a Level 2/3 study of whitewater boating in either the Upper Gorge or the West Branch downstream from Stone Dam because there is sufficient information about the boatability of these two reaches to assess the effects of project operations and inform any need for license conditions.

Discussion and Recommendation

*Upper Gorge*

The Upper Gorge boating reach is a short, 0.75-mile-long section and boating within this reach is at an advanced or expert level with limited opportunity for egress or emergency rescue. Access to the put-in is gained by walking or driving across Ripogenus Dam. No commercially guided trips are offered on this section.

GLHA obtained ten interviews for this reach, which included experienced paddlers and professional guides [section 5.9(b)(6)]. Two of the interviewees self-reported paddling the reach hundreds of times and two other interviewees reported paddling the reach more than ten times. These interviewees shared their experiences with multiple flows and based on their experiences were able to provide context as to how these flows compared to one another. Eight of the ten interviewees reported that this reach of river provided a better whitewater experience than other reaches in the region. However, multiple interviewees noted that portaging would be very difficult and infeasible based on the steep-sided nature of the gorge.

The interviewees described flows in the 2,000-3,500 cfs range as 'really good' or 'just right.' Additionally, GLHA obtained and reviewed several videos documenting the entire reach at multiple flow conditions. These videos, in combination with the number and quality of interviews performed for this reach provide ample information regarding the suitability of various flows for whitewater boating [section 5.9(b)(7)]. The interviews and videos also make clear that the Upper Gorge provides a Class III-V boating experience at most flows, and that it is best suited for experienced, expert paddlers.

Based on the reach's existing information, short length (when compared to other nearby reaches on the West Branch), safety concerns, limited access, and remote setting, we do not recommend that GLHA conduct a Whittaker Level 2 or Level 3 Study for this reach.

*West Branch Below Stone Dam*

Currently, there is no formal put-in for this reach, and interviewees reported paddling across Quakish Lake for about 2 miles and portaging Stone Dam to gain access. Releases from Stone Dam are typically made by deflating the dam, which could provide an opportunity for whitewater recreation. GLHA obtained only two interviews for this reach.

A Whittaker Level 2 study would identify the reach's flow-dependent attributes, assess the feasibility and potential quality of boating opportunities there, and estimate flow ranges by boating the river. Due to the location of this reach near Millinocket and the lack of a sufficient number of interviews to determine potential boating opportunities, we recommend that GLHA: (1) proceed to a Whittaker Level 2 study for this reach; and (2) explore ways to increase access to this reach with stakeholders and study participants. This information should be included in an updated *Whitewater Boating Assessment Report* and filed with the USR. We are not recommending a Level 3 study for this reach due to the configuration of Stone Dam, which, having an inflatable, rubber dam, is not designed to provide consistent and predictable flow releases.

*Millinocket Stream*

GLHA completed 26 interviews for this reach and received general consensus that the minimum boatable flow is in the 400 to 500 cfs range, which is generally consistent with the findings on the whitewater boating study conducted during the previous relicensing [section 5.9(b)(4)]. The majority of interviewees reported an excellent experience boating this reach. Therefore, we do not recommend a Level 2/3 Study for this reach.

**18. Aesthetics Study**

Background

The SPD required GLHA to conduct a study of aesthetics at the projects. The first-year study, based on the Bureau of Land Management's Visual Resource Management methodology, documented the scenic views, vistas, riverscapes, and other noteworthy features of the Ripogenus and Penobscot Mills Projects from Key Observation Points (KOPs) where the projects are frequently viewed by the public. The first-year study was designed to augment and update existing information on the scenic and visual resources provided at the projects from various KOPs. GLHA identified KOP locations (which were described in the Revised Study Plan filed with the Commission on March 23, 2023) and conducted an initial field inventory and photo documentation of aesthetic resources from the KOP locations. The SPD also required the *Aesthetics Study* to be conducted in consultation with Maine BPL, AW/AMC, the Camp Associations, and

other interested stakeholders. The ISR indicated that this was not done in 2022. Instead, GLHA collected baseline photo documentation of noteworthy features and is now proposing to assemble a focus group to participate in supplementing the existing information on aesthetics at the projects.

Proposed Study Modifications

In its comments, AW/AMC and the Camp Associations request that GLHA complete the *Aesthetics Study* consistent with the methodology required by the SPD. Specifically, AW/AMC request that the study be conducted in consultation with Maine BPL, AW/AMC, the Camp Associations, and other interested stakeholders.

In its comments, Maine BPL requests that GLHA undertake an aesthetic evaluation of the views of the Upper Gorge from Ripogenus Dam and the Upper Gorge trail under various spill or scheduled whitewater flows, using the existing KOP evaluation form.

Comments on Requested Study Modifications

In its reply comments, GLHA proposed to convene a focus group of interested stakeholders to review the information gathered from the 2022 *Aesthetics Study* and identify potential additional KOPs for land and water that should be evaluated in the 2023 study.[61] GLHA proposes to work with the focus group to develop a plan to visit the selected KOPs for in-person evaluation. During this site visit, stakeholder focus group participants would evaluate the aesthetic value of the selected KOPs using the Bureau of Land Management (BLM) Visual Resource Management (VRM) methodology. The site visits would also be used to further discuss the aesthetics of project lands and waters. The results of this evaluation would supplement the existing aesthetics information provided in the *Aesthetics Study Report* filed with the ISR.

Discussion and Recommendation

GLHA's proposal would allow stakeholders to participate in identification of KOPs [section 5.9(b)(4)] and assigning weight to individual KOPs. Thus, we recommend that GLHA continue the *Aesthetics Study* with its proposed modifications, as the new proposal appears to capture the requested modifications and be consistent with the requirements of the SPD.

[61] GLHA anticipates holding the initial virtual focus group meeting in September, and the in-person meeting and site visit in October.

**20. Socioeconomics and Environmental Justice**

Background

In the SPD, staff stated that a description of socioeconomic conditions would be required in the final license application, and that information, along with the *Environmental Justice Study* results, would be sufficient to address existing information gaps regarding the effect of continuing to operate the Ripogenus Project and Penobscot Mills Project on socioeconomics and environmental justice communities. The SPD required that the *Environmental Justice Study* be conducted in consultation with the Penobscot Indian Nation and other relicensing stakeholders. In 2022, GLHA conducted an *Environmental Justice Study* to assess the projects' potential to impact minority and low-income populations in the project vicinity but the information in the ISR does not contain any consultation record with the Penobscot Indian Nation or other relicensing stakeholders. At the ISR Meeting, GLHA stated that it is approaching the study in two phases and that the second phase will include additional outreach, including with the Penobscot Indian Nation.

Requested Study Modifications

In its comments, Maine PRO expresses concern with the exclusion of the *Socioeconomic Study* proposed by the Penobscot Indian Nation and comments on the importance of preserving and enhancing outdoor industries.

In its comments, AW/AMC states that the 1-mile study area is overly narrow, and that the *Environmental Justice Study* should address project effects on the Penobscot Indian Nation, other indigenous groups, and individuals. AW/AMC also comments that the study failed to conduct outreach to the Penobscot Indian Nation or engage other stakeholder groups, and that project-related effects associated with current operation were not examined.

In its comments, Maine TU describes how the 1-mile study area is narrow and does not encompass the impacted communities. Maine TU requests a modified study with language clarifying the inclusion of the Penobscot Indian Nation. and the effects of mill closures on the tribe in terms of environmental justice.

Comments on Requested Study Modifications

In its third Study Progress Report,[62] GLHA indicates that it is the process of consulting with the Penobscot Indian Nation. GLHA also indicates that it is planning

[62] *See* GLHA's August 1, 2023, Filing.

additional outreach to members of identified Environmental Justice communities, and that data collected in 2023 will be provided in the USR.

Discussion and Recommendation

GLHA's *Environmental Justice Study* identified low-income environmental justice communities in five of the eight census block groups within the study area. However, the SPD required that the study be conducted in consultation with the Penobscot Indian Nation and other relicensing stakeholders. Therefore, the study must be conducted in consultation with the Penobscot Indian Nation and other relicensing stakeholders.

Regarding the scope of the study area, expanding the buffer may allow for more of the impacted communities to be included. Therefore, we recommend expanding the study to include a 5-mile buffer instead of the 1-mile buffer [section 5.9(b)(4)]. In addition, we recommend updating the analysis with the most current 2021 ACS data.

# APPENDIX C

## STAFF RECOMMENDATION ON REQUESTED NEW STUDIES

### McKay Station Fish Stranding Mitigation Study and McKay Station Ramping Rate Study

Background

The May 13, 2022, Study Plan Determination (SPD) required Great Lakes Hydro American (GLHA) to conduct a *Fish Stranding Study* in the West Branch of the Penobscot River (West Branch) downstream from McKay Station. The study was designed to evaluate the amount of stranding and mortality associated with a station trip[63] at McKay Station, when flows would drop quickly from generation releases (about 2,000 cubic feet per second; cfs) to 510 cfs.[64] The specific goals of the study were to assess the frequency and duration of unplanned outages at the Ripogenus Project, and to determine whether the outage flow strands fish in the West Branch of the Penobscot River (West Branch) between McKay Station and Nesowadnehunk Falls. The study area was divided into seven reaches within an approximately 5.2-mile stretch of river downstream from McKay Station.[65]

### McKay Station Fish Stranding Mitigation Study

Background (Cont.)

The *Fish Stranding Study*, which lasted about 4.5 hours (from 9:30 am to 2:00 pm), was conducted on October 5, 2022, by simulating an outage at McKay Station and observing the seven study reaches to document instances of fish or macroinvertebrate stranding. GLHA installed temporary staff gages in four of the study reaches (Holbrook

[63] Station trip, as defined herein, refers to an event where the generating units at the hydro station trip offline due to an unplanned outage.

[64] The SPD required that a minimum flow of 400 cfs be passed in simulating a station trip. However, due to the installation of a new breaker system for the generating units at McKay Station, the minimum flow now passed through the unit(s) during a station trip is 510 cfs.

[65] The areas included the Holbrook Side Channel (0.8 miles downstream), West Branch at the Holbrook Side Channel (0.8 miles downstream), West Branch at Telos Bridge (1.1 miles downstream), West Branch at Big Eddy (1.6 miles downstream), West Branch at Little Ambejackmockamus Falls (Little A Falls; 2.6 miles downstream) and Big Ambejackmockamus Falls (Big A Falls; 3.6 miles downstream), and West Branch at Nesowadnehunk Deadwater (5.2 miles downstream).

Side Channel, Telos Bridge, Little A Falls, and Nesowadnehunk Deadwater) to assess the effect of the simulated station trip on the duration and magnitude of changes to river levels.

During the simulated station trip event, fish and macroinvertebrate strandings in the designated study reaches were observed and recorded. Field teams were composed of two or more individuals, one of whom was a biologist or experienced angler. Study personnel waded and walked the perimeter of each study reach on foot, or navigated by boat, to document any stranded fish or macroinvertebrates observed. The field teams took photographs or videos of stranded fish and aquatic habitat during the simulated event. In addition, a drone was used at the Telos Bridge and Big Eddy reaches to provide wide-area coverage and observations in areas that were challenging to access by foot or boat. The drone provided geo-referenced high-resolution video and still photo images. Observations of each species at each site were categorized by relative abundance.

GLHA's *Fish Stranding Study* documented changes (drops) in water elevation at the time of the simulated station trip ranging from 1.4 feet at the Nesowadnehunk Deadwater site to 3.4 feet at the Telos Bridge site. Water levels in the Holbrook Side Channel were not affected by the drop in flow. The rate of change in water surface elevations and reductions in water depth was greatest at the upper sites in the study area (Telos Bridge, Big Eddy, Little A Falls, and Big A Falls). GLHA's report, as well as a fish stranding report of the same event filed by the Maine Council of Trout Unlimited (Maine TU) on October 19, 2022,[66] show that dropping flow at McKay Station from generation releases to 510 cfs resulted in fish and macroinvertebrate stranding and mortality, especially for juvenile landlocked salmon, blacknose dace, and brook trout.

Requested Study

During the Initial Study Report (ISR) Meeting, Commission staff observed that, while the methodologies and geographic scope of GLHA's and Maine TU's studies varied somewhat, the results of both studies show that stranding and mortality of aquatic organisms is occurring during unplanned outages at McKay Station. In our July 6, 2023, comments on the ISR, we noted that a next step would be to determine the frequency and significance of the fish stranding/mortality events, and if the events warrant mitigative measures.

[66] *See* https://elibrary.ferc.gov/eLibrary/filedownload?fileid=086DE661-0456-C845-A09B-83F0C9000000.

Comments on the Requested Study

In its comments, Maine TU states that the fish stranding studies show that station trip events result in "significant" stranding and mortality of fish and macroinvertebrates, and comments that if such flows occurred during the hot summer months or the cold winter months, additional mortality is expected. In its comments, the Maine Department of Fisheries & Wildlife (Maine DIFW) comments on the need to minimize low-flow events caused by unplanned outages at McKay Station. Neither Maine TU, nor Maine DIFW, however, requested specific modifications to the *Fish Stranding Study*.[67]

Discussion and Recommendation

GLHA's *Fish Stranding Study* documented fish and macroinvertebrates that were completely out of the water due to the rapid decrease in water levels, as well as fish and macroinvertebrates that were trapped in isolated pools or shallow, wetted areas. Areas of boulder and cobble bars, bedrock ledges, and fine substrates (e.g., sand and silt) were exposed through much of the area observed at the low flow of 510 cfs; though, much of the main river channel remained wetted. Juvenile landlocked Atlantic salmon and blacknose dace represented the majority of fish strandings; 55% and 31%, respectively, of the total 446 fish counted. Of the 247 juvenile salmon counted as stranded, 105 were observed to be dead (43%). For blacknose dace, 75% of the observed stranded fish were dead.

Given that this study occurred in October, it could represent a best-case scenario. It is reasonable to expect that the effect would likely be greater if the event were to occur in the (a) summer when air and water temperature are warmer and dissolved oxygen (DO) concentrations are lower, or (b) in the winter when the air and water temperature are colder. The observed level of mortality associated with station trips has a negative effect on landlocked salmon in the West Branch downstream from McKay Station [section 5.9(b)(5)].

The first study season findings of the *Fish Stranding Study* highlight the potential need to mitigate the fish and invertebrate stranding and mortality described above [section 5.15(e)(2)]. Therefore, we recommend that GLHA conduct a second study season *McKay Station Fish Stranding Mitigation Study* to identify and assess measures to minimize the level of fish and macroinvertebrate stranding and mortality that occurs when McKay Station trips offline. GLHA would consult with the U.S. Fish and Wildlife Service (FWS), Maine DIFW, and Maine TU to determine: (1) what effect the unplanned outages at McKay Station have on the fish and macroinvertebrate populations in the West

[67] Maine TU requested a *Ramping Rate Study* for the West Branch downstream from McKay Station, which also is discussed herein.

Branch downstream from McKay Station; and (2) if appropriate, identify potential ways to address fish and macroinvertebrate stranding and mortality downstream from McKay Station.[68] The results of this effort would be added to the first season findings in a final *Fish Stranding Study Report* provided with the Updated Study Report (USR).

**McKay Station Ramping Rate Study**

Requested Study

Also, based on the results of the *Fish Stranding Study*, Maine TU recommends that GLHA conduct a *McKay Station Ramping Rate Study* at, and downstream from, the Ripogenus Project to explore protocols for changing flows at McKay Station that could reduce or eliminate stranding and mortality of fish in the West Branch.[69] Maine TU's recommended study would follow the methodology used to determine ramping rates for the Magpie River in Quebec, Canada. The study would be conducted in early October; and whitewater flows of 2,000 to 2,400 cfs would be discharged for a week prior to the study commencing. Maine TU recommends the evaluation include a range of flows from the station's hydraulic capacity to 500 cfs (close to the station outage event flow). If stranding occurs at the initial ramping rate chosen for the study, the ramping protocol would be repeated on subsequent days at slower ramping rates until the safest ramping rate is identified. No other details regarding the study's methodology are provided by Maine TU.

Comments on the Requested Study

In their comments, the National Marine Fisheries Service and the Maine Department of Marine Resources recommend approval of Maine TU's request for a ramping rate study for the West Branch downstream from McKay Station. In its comments, Maine DIFW expresses concern with how Ripogenus Project operations may have changed since the Millinocket paper mills closed. Maine DIFW perceives that the

[68] Examples of measures that could be considered include: (1) a minimum flow that reduces the amount of stranding that is occurring; (2) a battery back-up system that supplies power to a unit or units at McKay Station when the main power source is unavailable, which would reduce the amount of time at the low flow; (3) automating a gate at Ripogenus Dam so that when McKay Station trips offline a gate opens to release a preset minimum flow to the West Branch downstream from Ripogenus Dam; etc.

[69] Though both the first season *Fish Stranding Study* and the recommended second season *McKay Station Ramping Rate Study* are concerned with stranding and mortality of aquatic organisms downstream of McKay Station, the studies differ in that the former addresses system shutdowns and the latter addresses normal changes in turbine operations.

frequency and rate of change in discharge to the West Branch downstream from McKay Station may have increased in the modern, "post-mill" era.

Reply Comments

In its reply comments, GLHA proposes to conduct a *McKay Station Ramping Rate Study* at the Ripogenus Project. The study would evaluate two change-in-flow scenarios. The first scenario would entail going from 3-unit operation (~3,500 cfs) to 1-unit operation (~1,100 cfs) by simultaneously shutting down two units.[70] The second scenario would entail going from 3-unit operation (~3,500 cfs) to 2-unit operation (~2,300 cfs) to 1-unit operation (~1,100 cfs); holding at 2-unit operation for an hour before going to 1-unit operation. In addition, the study would include a review of the "post-mill" operational data (2014 through 2022) to identify the frequency of hourly changes in operations when changing from three units to two units, three units to one unit, and two units to one unit.

The study area for the *McKay Station Ramping Rate Study* would include the West Branch between McKay Station and Little A Falls. Within the study area, GLHA would focus on three of the seven study reaches that were part of the *Fish Stranding Study*: (1) the main stem of the West Branch (upstream of the Holbrook Side Channel); (2) riffle habitat immediately downstream from the Big Eddy pool; and (3) riffle habitat in the upper section of Little A Falls. The study would be conducted in the fall (prior to October 15, 2023), and GLHA would conduct the field study evaluation immediately after whitewater flows, ranging from 2,000 cfs to 2,400 cfs, have occurred for at least 1 week, if possible.

Field crews[71] would observe and measure changes in river conditions and aquatic habitat within the three study reaches during changes in unit operations for the two scenarios. Changes in river stage within the study reaches would be measured with water level loggers programmed to collect data at 5-minute intervals. Changes in wetted width also would be collected at two to four cross sections within each of the three study reaches using a range finder or comparable method. The data collected would be used to evaluate the effects of the rate of change of flow on water depth and wetted area habitat

[70] Based on historical operations (see hourly operations data filed with the Initial Study Report Meeting Summary), the units vibrate significantly at gate positions less than 70% to 80% of maximum hydraulic capacity, depending on reservoir level. Therefore, under typical project operations, compared to an extended ramping of the units during startup or shutdown, the units are operated to rapidly move through the vibration zones to avoid damage to the units.

[71] Field crews would consist of representatives of GLHA, Maine DIFW, and Maine TU.

conditions, as well as to compare the differences in flow rate change effects on habitat conditions under the two scenarios to determine if there would be a beneficial "ramping" rate effect associate with the three-to-two-to-one unit operation scenario.

Field crews also would perform reconnaissance surveys in the three study reaches, employing methodology like that used for the *Fish Stranding Study*, to determine the extent to which fish and macroinvertebrate stranding occur under different in ramping operations.

Discussion and Recommendation

The *Fish Stranding Study* documented that fish and macroinvertebrate stranding occurs with an abrupt change in flows from 2,000 cfs to 500 cfs (i.e., station trip event) [section 5.15(e)(4) and sections 5.9(b)(4)]. Juvenile landlocked salmon are particularly susceptible to such abrupt flow changes. However, neither the *Fish Stranding Study*, nor any other study required by the SPD, provide information on flow levels or alternative means of project operations (e.g., ramping) to prevent mortality of aquatic organisms resulting from rapid flow changes [section 5.9(b)(4)]. Thus, the results of a ramping rate study would provide information important to evaluating the effects of changes in unit operations on aquatic resources and habitat across the range of project discharges and could inform the development of license conditions [section 5.9(b)(6)]. For these reasons, we recommend: (1) GLHA conduct its proposed *McKay Station Ramping Rate Study*, after consulting on final details of the study and its implementation with Maine DIFW and Maine TU; and (2) the *McKay Station Ramping Rate Study Report* be filed with the USR

Regarding Maine TU's request to evaluate a flow of 500 cfs, there is no need to include such a low flow as part of the ramping rate study. The discharge only drops that low when there is a system trip, the effects of which were documented in the first season *Fish Standing Study*. Above, we have also recommended a *McKay Station Fish Stranding Mitigation Study* in a second season to supplement the *Fish Stranding Study Report* with potential strategies to reduce effects of system trips, if feasible.

**Smelt Study**

Background

The SPD included a *Fish Assemblage Study* of the Ripogenus impoundment and the West Branch downstream from Ripogenus Dam. GLHA conducted the study and documented the presence of smelt in the Ripogenus Impoundment, as well as the occurrence of smelt "drift" through McKay Station downstream to the West Branch.

Requested Study

Edward Spear states that the smelt information included in the ISR shows a population of larger-sized smelt that are too big to serve as prey for adult landlocked salmon. Mr. Spear claims that, in addition to cannibalism; reduced abundance of zooplankton; reduced, fluctuating, or lost littoral areas; a reduced volume of water between surface- and deep-water layers in the impoundment (or metalimnion); and turbidity are known factors affecting smelt populations. Mr. Spear recommends that GLHA conduct a smelt study of the Ripogenus impoundment that focuses on spawning, egg survival, fry escapement, zooplankton availability (with an emphasis on rotifers), and survival of smelt through their first year. The goal of this study would be to assess the status of the Ripogenus smelt population by following an age class from egg to Age 1, as well as to determine the contribution, if any, of this cohort to the prey base in the West Branch downstream from McKay Station and the salmonid fishery.

Mr. Spear recommends that the study involve documenting smelt spawning escapement in a Ripogenus impoundment tributary (e.g., Ragged Stream). Spawning success would be measured following methods described in a Maine DIFW report, "Developing Catch Indices for Rainbow Smelt Fry Outmigration on North Brook, Lily Bay Moosehead Lake." The distribution and timing of larval juvenile smelt outmigration would be determined using: (1) bi-weekly (vertical) plankton tows; and (2) horizontal larval smelt sampling with oblique plankton trawls, beginning in the shoreline littoral area and continuing into the pelagic (open water) zone. Lake sampling would extend from the spring into October. Smelt "drift" through McKay Station would also be sampled, but appropriate methods have not been described.

Reply Comments

In its reply comments, GLHA does not propose the smelt study requested by Mr. Spear.

Discussion and Recommendation

Edward Spear, in a letter filed on January 27, 2022, requested a study to determine the status of the zooplankton population in the Ripogenus impoundment, and its relationship to larval and juvenile smelt. In requesting the study, Mr. Spear cited to the current quality of the landlocked Atlantic salmon fishery in the Ripogenus impoundment, which he argued at the time was in decline. Mr. Spear provides similar reasoning on the need here for the smelt study, with little additional support or explanation as to how such a study would inform a licensing decision [sections 5.9(b)(4) and (b)(5)].

The results of the *Fish Assemblage Study*, as presented in section 5.0, *Results*, of Appendix D to the ISR, along with Great Northern Paper's historical sampling data and

Maine DIFW's past and on-going smelt "drift" studies are sufficient for an analysis of the effects of project operation on the smelt population in the Ripogenus impoundment and the amount of smelt drift downstream into the West Branch [section 5.9(b)(5)]. There has been no material change(s) in the law or regulations applicable to the information request [section 5.15(e)(1)], nor has there been a significant change in the project proposal or significant new information material to the study objectives that has become available [section 5.15(e)(4)]. Based on these factors, coupled with the adequacy of the information in the record, we do not recommend that GLHA conduct the *Smelt Study*.

**West Branch Creel Survey**

Background

In his comments on the Proposed Study Plan, Edward Spear requested that GLHA conduct a creel survey on the West Branch employing the methods used in the 1978 creel surveys that were conducted in support of the previous relicensing. The SPD did not approve Mr. Spear's requested Creel Survey. Instead, staff stated that during the ILP's study period, Maine DIFW would conduct periodic creel surveys on the West Branch, which GLHA would then compile and synthesize. Further, the SPD required GLHA to modify the *Recreation Study*, to include questions about fishing activities on the survey of recreation users. GLHA added these questions to the Recreation Survey.

Requested Study

In their comments, Maine TU and Mr. Edward Spear request that GLHA be required to fund a Maine DIFW-designed, managed, and staffed creel survey of the West Branch between Ripogenus Dam and Abol Bridge.

Comments on the Requested Study

In its comments, Maine DIFW provides its rationale for not requesting clerk angler surveys as part of the relicensing.[72] The reasons include: (1) the need for consistency and repeatability in survey methodology; (2) the availability of ample, recent angler survey data from summer and winter 2021 collected by Maine DIFW; (3) the fact that Maine DIFW has the information currently needed to assess the fishery and respond with management changes, as necessary; and (4) plans by Maine DIFW to survey the Ripogenus Project and the West Branch in 2025.

[72] In creel surveys, a clerk is the person that administers the survey.

Reply Comments

In its reply comments, GLHA states that it included creel survey information collected by Maine DIFW in 2021 and 2022 for the West Branch downstream from McKay Station in the *Fish Assemblage Study Report*. Also, in the ISR, GLHA included responses to the fishing-related questions that were added to the recreational survey questionnaire.[73] In response to GLHA's reply comments, Mr. Spear discusses additional issues from the first year study efforts and results and states that, despite existing information, there is still a need for West Branch creel surveys to define recreational angler use (days fished), effort (hours fished), catch (legal and sub-legal salmon and brook trout catches), and river reach fished.

Discussion and Recommendation

Several commenters noted the low number of surveys and near absence of data on winter use from the first-year study. To collect additional recreational user surveys, GLHA reinstalled survey kiosks in July 2023, which will be available through March 2024 to obtain more data on the recreational fishery. This approach would require less effort than conducting a separate creel survey [section 5.9(b)(7)] and would assist in more accurately describing the fishery in the environmental document for the projects. Moreover, Maine DIFW's existing data, as well as information from the upcoming 2025 surveys, along with GLHA's survey efforts would provide sufficient information to inform a licensing decision [section 5.9(b)(5)]. For these reasons, we do not recommend that GLHA conduct the *Creel Survey*.

**USGS Gage Feasibility Study**

Background

There are no streamflow gages installed on the West Branch to determine flow in the river. Rather, GLHA currently determines flows in the river, throughout the Ripogenus and Penobscot Mills Project areas using generation records from the projects.

[73] Survey respondents were asked to provide information on the species targeted, length of time fishing, species caught, and the size of fish caught. For the Ripogenus Project recreation sites, 48 respondents answered the question of what species of fish were targeted. Respondents indicated that they were targeting 11 different species, including landlocked salmon, brook trout, white perch, lake trout, brown trout, yellow perch, splake, cusk, chub, lake whitefish, and white sucker. The dominant species caught were landlocked salmon, brook trout, white perch, and chub. The average and median amount of time respondents spent fishing were 7.8 hours and 4 hours, respectively, with a range of 0.5 to 72 hours.

Requested Study

Maine DIFW recommends that GLHA work with the U.S. Geological Survey (USGS) to determine the feasibility and cost for a new USGS gage on the West Branch at a location downstream from McKay Station and upstream of the Big Eddy Campground.

Comments on the Requested Study

In its reply comments, GLHA does not propose the *USGS Gage Feasibility Study* requested by Maine DIFW.

Discussion and Recommendation

The Preliminary Application Document indicates, in section 4.0, *Outflow Records*, on page 4-51, that there are no flow gages immediately upstream of, within, or immediately downstream from, the Ripogenus and the Penobscot Mills Projects. The lack of streamflow gaging has raised concerns regarding flow monitoring at the projects, especially the Ripogenus Project, and the need for streamflow gaging was raised at the ISR meeting and in comments on the ISR. Given these concerns, we intend to evaluate alternatives for streamflow monitoring as part of our environmental review of the proposed projects. Having information on alternatives for monitoring streamflow, including the feasibility and costs of the alternatives, would be necessary for our analysis. Maine DIFW's requested study would provide information on the feasibility and cost of installing a USGS streamflow gage(s) that would be connected to the internet, on the West Branch [section 5.9(b)(4)]. For these reasons, we recommend that GLHA evaluate alternatives for monitoring streamflow at the projects, including the installation of a USGS streamflow gage on the West Branch downstream from McKay Station. We also recommend that the specific study details be development in consultation with USGS and Maine DIFW, and the resulting report be filed with the USR.

**Penobscot Mills Bypass Channel Fishability/Wadability Study**

Background

Under the current license, minimum flows are not required in the West Branch of the Penobscot River downstream from Stone Dam (which is part of the Millinocket Development). This reach is about 4.5 miles long and flows into Shad Pond. The results of the *Instream Flow and Habitat Assessment Study for the West Branch of the Penobscot River downstream from Stone Dam* show that a flow of about 700 cfs appears to be optimal for landlocked Atlantic salmon. However, flows that may be optimal for fish are not always optimal for wading anglers. Anticipating a potential future minimum flow release requirement for Stone Dam, Maine DIFW plans to assess the viability of a limited salmonid stocking program for this stretch of the West Branch of the Penobscot River.

Maine DIFW states that, given the rugged nature of this reach, lack of previous flow data, and site-specific information, a fishability/wadability study is necessary to evaluate safe angler access to, and within, this reach.

Requested Study

Maine DIFW requests that GLHA conduct a fishability/wadability study in the West Branch downstream from Stone Dam. The goal of this study would be to identify the range of flows that allow for safe wading and fishability. Maine DIFW states that the study is needed to ensure that any agreed upon flow releases for salmonid habitat are wadable and fishable. Maine DIFW also states that the study would be a collaborative effort (selecting survey locations and test flows, etc.) between Maine DIFW, GLHA, and other interested stakeholders. Maine DIFW's recommended study would consist of anglers assessing river wading conditions and fishability across an agreed-upon range of flows[74] at locations within the West Branch of the Penobscot River downstream from Stone Dam.

Comments on the Requested Study

In its comments, Maine TU supports a wadability study in the river reach downstream from Stone Dam to determine how best to optimize the area for fishing, as well as additional whitewater boating opportunities. In his comments, Edward Spear requests adding a component that would address wading in the reach, or "how anglers would move up and down this river segment to reach the fish."

Reply Comments

In its reply comments, GLHA proposes to conduct a *Penobscot Mills Bypass Channel Fishability/Wadability Study*. As with Maine DIFW, the goal of the study would be to evaluate conditions that allow safe wading and fishability under a range of flows suitable for improving salmonid habitat. The study area would be the West Branch between Stone Dam and Grand Falls.[75] As described in detail in Appendix D of its August 7, 2023, reply comments, GLHA's proposed methodology involves a phased approach that includes an angler assessment component and use of the existing Instream

[74] The actual test flows would be selected through a collaborative process involving Maine DIFW, GLHA, and other interested stakeholders (e.g., area guides, local anglers, and Maine TU).

[75] Inflow from Quakish Lake enters the study area over the spillway at Stone Dam whenever inflow exceeds the hydraulic capacity of operating units at the Millinocket Development and/or wind fetch and waves introduce uncontrolled spillage.

Flow Incremental Methodology model to simulate conditions that affect wading conditions and fishability in the reach.

GLHA proposes to assemble a study team of about 10 experienced anglers familiar with this type of fishing, potentially composed of Maine DIFW personnel, area guides, local anglers, Maine TU, and other interested stakeholders. The angling team would conduct a site visit to the study area for orientation and to provide input on preferred angling sites. The initial site visit would also be used to evaluate wading conditions and fishability at existing leakage flow (estimated to vary between 17 cfs and 100 cfs). Each angler would be encouraged to wade, cast, and otherwise fish the water, and would be provided with a questionnaire soliciting rating input on the parameters above (*see*, e.g., Attachment 1 of Appendix D to GLHA's reply comments). The goal of this exercise is to generate site-specific input on suitable wading depths and ability to cast to fish holding areas. This effort would be followed by a discussion to determine if it would be feasible, or necessary, to reconvene the angling team on another day when GLHA would attempt to provide a higher flow in the range of 400-700 cfs. Flow would be measured throughout the day, during this event, and the angling team would repeat their field evaluation of angling conditions at that flow.

GLHA would apply the existing Physical Habitat Simulation (PHABSIM) model to evaluate angling suitability at flow increments not feasible to evaluate empirically. GLHA would use the 3-D spatial analysis heat map tool within PHABSIM to show specific patches of highly suitable brook trout habitat at each designated flow of interest. Patches of habitat that were considered as good to optimal would be identified and highlighted. These areas would have a high probability of holding adult brook trout at the evaluated flow, and, thus, would be considered as 'fish lies,' or desirable angling areas.[76] The casting distance relative to the desirable fish lie would be calculated to determine fishability at each flow, and from this the relative fishability of each flow of interest would be determined.

Discussion and Recommendation

The *Instream Flow and Habitat Assessment Study for the West Branch of the Penobscot River downstream from Stone Dam Study* shows that a flow of 300 to 400 cfs would increase wetted area and substantially improve the availability and suitability of habitat for brook trout (juveniles and adults), land-locked salmon juveniles, and

[76] The exact range of suitability to be considered fish lies would be developed in consultation with Maine DIFW brook trout experts.

macroinvertebrates in the reach.[77] The model estimated that habitat suitability for juvenile and adult brook trout, as well as juvenile land-locked salmon would increase with flow up to 500 cfs (juvenile trout and salmon) and 700 cfs (adult trout), before declining at higher flows. Habitat suitability for land-locked salmon adults would increase with flow up to the maximum flow of 2,000 cfs, and habitat for macroinvertebrates would increase with flow up to 1,000 cfs before declining. According to the study report, the predominate substrate in this reach is boulder (above Great Falls) and boulder and bedrock ledge in the lower reach (below Great Falls). Thus, flows necessary to establish suitable aquatic habitat for salmonids in the reach may create unsafe conditions for wading and fishing in the reach (i.e., the ability for anglers to safely wade and fish).

The SPD required GLHA to assess flows and aquatic habitat needs in the West Branch downstream from Stone Dam but did not require GLHA to assess the wading conditions and fishability of the range of flows studied [section 5.9(b)(4)]. Such an evaluation is necessary to determine suitable and safe wading and fishing flows, while also maintaining adequate salmonid habitat in the river reach [section 5.9(b)(5)]. However, the study, as requested by Maine DIFW may not work at Stone Dam. Maine DIFW's requested study envisions a visual assessment at different flows. As noted by GLHA, however, Stone Dam is not equipped with gates that can be opened to provide specific flows. Moreover, the approximate 4-mile length of the study reach could require a day for conditions to stabilize at each potential assessment flow. GLHA's proposed study methodology is a reasonable alternative to Maine DIFW's recommended methodology that would require a multi-day effort [section 5.9(b)(6)] and is sufficient to evaluate wading conditions and fishability at different flows in the West Branch downstream from Stone Dam [section 5.9(b)(5)].

In our comments on the ISR, we requested that GLHA: (1) address the suitability of the reach for angling under the range of flows studied; and (2) identify the flow (or flow range) where the reach is no longer suitable for wading, in the *final Instream Flow and Habitat Assessment Study (Stone Dam) Report*. Consistent with our comments, we recommend GLHA conduct its proposed *Penobscot Mills Bypass Channel Fishability/ Wadability Study*, which would make use of the PHABSIM model at higher flows. We also recommend the study be designed to: (1) address the suitability of the reach for angling under the range of flows studied for brook trout and landlocked salmon; and

[77] The actual suitability of habitat gained with increased flow, however, would be limited by water temperatures in the reach during the summer months. Water temperatures in 2022 averaged about 23 °C (73 °F), with a range from around 18 to 28 °C (64 to 82 °F). These temperatures would be more conducive to the year-round survival of land-locked Atlantic salmon than to brook trout. *See* GLHA's *Downstream Water Temperature and Dissolved Oxygen Study Report*.

(2) because the proposed study plan is not clear on how flows would be rated as to their suitability for angling, identify the flows at which conditions are and are not suitable for wading and fishing. The results would be included in the final *Instream Flow and Habitat Assessment Study (Stone Dam) Report*. We also recommend that the study be designed and implemented in consultation with Maine DIFW, FWS, the Maine Department of Environmental Protection, Maine TU, and any other interested entity.

**Umbazooksus Lake Mitigation Evaluation Study**

Background

The SPD required GLHA to conduct a *Riparian and Littoral Habitat Assessment Study* for the Ripogenus Project and the Penobscot Mills Project. The goals of the study were to: (1) identify and characterize riparian and littoral habitat and quantify the exposed area within the historical fluctuation zones of the projects' storage impoundments (i.e., Ripogenus, North Twin, and Millinocket Lake Storage); (2) identify and characterize the existing wetlands within 200 feet of the three storage impoundments' normal full pond elevations; and (3) document observations of wildlife and invasive aquatic plant species within the projects' boundaries. The *Riparian and Littoral Habitat Assessment Study Report* provides information on: (1) impoundment water surface elevations and an assessment of exposed areas during drawdowns; (2) an assessment of wetland, riparian, and littoral habitat, including wetland mapping and characterization of the vegetation communities; (3) aquatic invasive plant species within the projects' boundaries; and (4) observed wildlife in the study areas. As pointed out by Maine DIFW, the effects of project operations on: (1) the downstream West Branch from the Ripogenus Project to the Penobscot Mills Project; (2) the West Branch downstream from Stone Dam; (3) Millinocket Stream; and (4) associated riverine wetland habitats was not considered as part of the *Riparian and Littoral Habitat Assessment Study*.[78]

Requested Study

In its comments, Maine DIFW states that it is concerned with the effects of project operation on riparian and littoral habitat along the flowing reaches of the West Branch and Millinocket Stream, and the species that occupy these areas. Maine DIFW states that its goal in this process is to consider ways to minimize and mitigate effects on lacustrine, palustrine, and riverine habitats and the species that use those habitats, including State

[78] Maine DIFW indicates that many State Species of Greatest Conservation Need, including state threatened aquatic or aquatic-associated invertebrate species in the project areas, require specialized experience, specific survey protocols, and proper seasonality to detect, and most of these species, if present, would not be documented through general wildlife surveys, as was done during the 2022 wildlife surveys.

Species of Greatest Conservation Need. To address these needs, Maine DIFW is interested in exploring whether the existing Umbazooksus Lake wetlands mitigation area, alone, is adequate to account for potential future effects of the projects' operations on riparian resources.

Maine DIFW requests a study to evaluate the Umbazooksus Lake wetlands mitigation area to determine whether it can be further enhanced as part of a new Ripogenus Project license. Maine DIFW proposes a Geographic Information System (GIS)-based study to evaluate wetlands at Umbazooksus Lake, with an increase in water levels at 1-foot increments, up to 4 feet, using the existing regime as the baseline. Maine DIFW requests that the study include: (1) the acreages and composition of modeled wetland types released at each level evaluated; (2) available aerial imagery or existing photographs; and (3) a narrative of wildlife resources expected to use each wetland type.

Comments on the Requested Study

In its reply comments, GLHA proposes to conduct Maine DIFW's requested *Umbazooksus Lake Mitigation Evaluation Study*, with modifications. The objectives of the proposed new study would be to: (1) perform a desktop characterization using FWS (2022) National Wetlands Inventory and other resources such as GIS-based topographic maps, hydrography, aerial imagery, and soil surveys to identify, describe, and classify wetlands and waterbodies (e.g., streams) within the study area (including littoral and riparian zones); (2) perform field verification surveys to confirm the location, dominant vegetative communities, and vegetation classifications identified in the desktop survey; (3) identify the dominant wetland vegetation in the study area to characterize the availability of wetland habitat; (4) document invasive plant species observed; (5) describe principal wetland functions and values; (6) document wildlife sightings during field surveys; and (7) develop a GIS-based map identifying wetlands and riparian and littoral vegetative community composition.

GLHA notes that the current mitigation and management strategy for Umbazooksus Lake consists of permanently opening the discharge gate to lower water levels and increase the wetland habitat at the lake. GLHA states that if the water surface elevation of Umbazooksus Lake was raised, it would decrease wetland habitat. Therefore, GLHA has not adopted Maine DIFW's request to evaluate the change in habitat resulting from a potential increase in the water surface elevation at Umbazooksus Lake.

Reply Comments

In comments filed on August 25, 2023, Maine DIFW states that GLHA did not provide information to support its claim that by raising the water level in the lake it would decrease the total acres of wetlands. Based on a preliminary analysis of aerial

imagery, Maine DIFW asserts that there would be, at a minimum, an increase in the level of interspersion in these areas, if not an increase in the total acres of wetlands. Maine DIFW also asserts that by increasing the interspersion of the fringe wetlands, wetland functions would improve, and acreage would increase. Maine DIFW states that these are important wetland types that are characteristic of high-quality wetlands and would support a diversity of wildlife, including waterfowl, wading birds, and aquatic furbearers.

In comments filed on August 30, 2023, GLHA states that the objective of the 1997 Wetland Enhancement Plan for Umbazooksus Lake was to increase the extent, density, and species diversity of wetland vegetation cover within the zone from the former full pond elevation down to about 6 feet below ordinary low water by: (1) lowering the average water level of the lake; (2) establishing a more consistent hydrologic regime from year-to-year; and (3) reducing the variability of water levels during the growing season. GLHA states that the wetlands at Umbazooksus Lake prior to implementation of the 1997 plan were limited to fringe emergent and shrub wetland types around the lake's shoreline. GLHA states that lowered lake levels were agreed to, based on extensive consultation with the agencies, to enhance the fringe wetland types that existed at the time and to establish new emergent and aquatic bed wetlands within the lake.

GLHA states that Maine DIFW's request to evaluate higher water levels at Umbazooksus Lake conflicts with the original intent and design of this mitigation measure. GLHA points out that monitoring has verified the intended results. GLHA proposes to collect contemporary data at Umbazooksus Lake to evaluate the current conditions in relation to the intended mitigation measure and the current relicensing of the projects.

Discussion and Recommendation

During the previous relicensing, the Commission determined that the ongoing operation of the projects resulted in diminished function of shoreline fringe wetlands due to dewatering during impoundment drawdowns.[79] The existing Ripogenus Project license required the development of the 1997 Wetland Enhancement Plan. The approved plan established the Umbazooksus Lake Mitigation Area. As noted above, the goal of plan was to increase the extent, density, and species diversity of wetland vegetation in Umbazooksus Lake, as well as establish a more consistent hydrologic regime and reduced the variability of water levels during the growing season. The 2005 Umbazooksus Lake Wetland Enhancement Final Report demonstrated that 320 acres of degraded wetland habitat were starting to recover by discontinuing the historic storage

[79] *See* Section 4.5 of Commission's 1996 Final Environmental Impact Statement for the Upper Penobscot River Basin, Maine FERC Project Nos: 2572 and 2548 (Volume 1).

and release operation. This was achieved by maintaining the outlet gate in a permanently open position and allowing water levels in the lake to fluctuate naturally from the inflow from the surrounding watershed and uncontrolled outflow through the gate. The total extent of vegetated wetlands surrounding Umbazooksus Lake increased by approximately 117 acres from 1998 to 2004. Overall, vegetative cover (i.e., density) increased over 350% in the areas formerly affected by project operation.

GLHA proposes to use available information, as well as information collected during studies in 2022 and 2023 to evaluate effects on riverine wetland habitats from project operations. However, Maine DIFW's proposed GIS-based study to evaluate wetlands at the Umbazooksus Lake mitigation area, including evaluating incremental increases in water levels in Umbazooksus Lake, would provide a quantitative means for Maine DIFW and GLHA to predict if the Umbazooksus Lake Mitigation Area can be further enhanced and to assess appropriate measures to address the effects of operating the projects on the downstream West Branch and its associated riverine wetland habitats [sections 5.9(b)(5) and 5.9(b)(6)].

GLHA states that Maine DIFW's request to evaluate higher water levels within Umbazooksus Lake conflicts with the original intent and design of 1997 Wetland Enhancement Plan. The 2005 final monitoring report indicates that there was a conversion of many areas from emergent to scrub-shrub emergent cover. A total of 320 acres of degraded wetlands associated with the former store-and-release operations showed signs of recovery, and the total extent of vegetated wetlands surrounding the lake increased by 117 acres after lowering the lake level. However, the plan estimated that an additional 280 acres of new shallows (i.e., area less than 6 feet in depth) would be created that had the potential to support the establishment of emergent and aquatic wetlands. Thus, the increase of 117 acres of new wetlands falls short of the 280-acre target. This suggests that there could be potential for further enhancement of wetlands around Umbazooksus Lake [section 5.9(b)(4)].

Based on the 2005 Umbazooksus Lake Wetland Enhancement Final Report, opening the outlet gate at Umbazooksus Lake, which can impound up to 6.5 feet of water behind the dam, lowered the level of the lake and allowed wetland habitat around the lake to recover. A study that includes a GIS-based assessment would help verify whether increasing the Umbazooksus Lake level would increase or decrease wetland habitat. Maine DIFW states that in its preliminary GIS-based assessment of increasing water levels at Umbazooksus Lake indicates that wetlands around the lake, as well as the function and diversity of the wetlands, could increase, whereas GLHA states that higher levels would conflict with the wetland enhancement plan currently being implemented. A study would help determine the best course of action.

Because riverine wetland habitats were not considered as part of the *Riparian and Littoral Habitat Assessment Study* [section 5.15(e)(2)] and for the reasons discussed

above, we recommend that GLHA conduct its proposed *Umbazooksus Lake Mitigation Evaluation Study* with modifications to include: (1) the GIS-based evaluation of wetland habitat requested by Maine DIFW, with increases in water surface elevations in the lake at 1-foot increments, up to 4 feet (existing regime would be the baseline); and (2) a description of wildlife resources expected to use each wetland type to supplement the data collected on species observed during the field surveys.

**Winter Recreation Access Study**

Background

The SPD required GLHA to evaluate recreation use during both the summer and winter recreation seasons as part of its *Recreation Study*. Thin ice conditions in winter 2022-2023 likely under-represented use.

Requested Study

In its comments, Maine DIFW requests an updated evaluation of winter angling access at the Ripogenus impoundment in the form of a *Winter Recreation Access Study*. Maine DIFW states that winter angling and snowmobile access is limited at the Chesuncook Point access site, which is the primary access site to the Ripogenus impoundment in the winter. Maine DIFW also states that it is important to maintain and promote winter angling and access on the impoundment. It is currently Maine DIFW's goal to increase harvest of salmon in the impoundment, and most of the annual salmon harvest occurs in the winter months.

In addition to its responsibilities regarding inland fisheries management, Maine DIFW indicates that it is charged with improving and securing public access to waters of the State of Maine. Maine DIFW requests the *Winter Recreation Access Study* because of concerns that use was under-represented in data collected this past winter as the ice formed very late, making it unsafe for travel and use through all of January. As a result, winter use was reduced in 2023 and, therefore, atypical during GLHA's *Recreation Study* period. Maine DIFW describes how its requested study should collect information on all recreation access points, including evaluating the capacity at the Chesuncook Point access site parking area and ease of access/conditions from the Golden Road, and determine overall use by area and by type. Maine DIFW recommends that the methodology include site visits on each Saturday between 10:00 am and 1:00 pm from January 15 through March 31.

Comments on the Requested Study

In its reply comments, GLHA indicates that it plans to convene a recreation and access focus group to obtain additional site-specific recreation and informal access

information, as well as concerns from interested stakeholders. Additionally, GLHA states that it redeployed the user survey kiosks at all project recreation sites in late July 2023 and plans to leave them in place through March 2024.

Discussion and Recommendation

Through GLHA's proposal to establish a recreation focus group, additional information on the project recreation sites would be collected, as well as information on informal, non-project recreation sites that provide important public access to project waters [sections 5.9(b)(4) and (b)(6)]. The information gathered would apply to all seasons, including winter. In addition, GLHA would be collecting winter use and access information through the redeployment of the survey kiosks at the project recreation sites, which would provide needed winter recreation use data. For these reasons, the effort of this separate survey would not provide additional insight into winter access and use at the Ripogenus Project [section 5.9(b)(7)]. Therefore, we do not recommend GLHA conduct the *Winter Recreation Access Study* requested by Maine DIFW.

Washington, DC 20426

Dear Secretary Bose, Via Electronic filing

Project Nos. 2572-133 & 2458-247, Determina. on on Requests for Study Modifications and New Studies for the Ripogenus and Penobscot Mills Hydroelectric Projects. 7. North Twin Impoundment Tributary Access Survey Study.

The above reference filing continues to reject MeDIFW logical and reasonable request for radio tagging of North Twin Impoundment adult Landlocked salmon, and to accept the Licensee's ill-founded logic while ignoring basic scientific facts. As proposed, the current study duplicates information found in the 1992 Application, albeit with "bells and whistles", i.e., photos and transects. The rocks, boulders, and tributary channels have not changed. Without radio telemetry, no new information will be provided.

,

FERC staff filing failed to discuss telemetry study requests; rather they referenced their decision made in a May 13, 2022 filing. (Study Plan Determination for the Ripogenus Hydroelectric Project and the Penobscot Mills Hydroelectric Project May 13, 2022 Study Plan Determination.) In summarily dismissing MeDIFW's request in the May 13, 2022 filing, they state "*radio telemetry study could track movement of salmon and potentially detect spawning behavior in these areas. However, such a study would have a significantly higher cost than that proposed by GLHA"* B17. This statement in not based on any cost information, and thus irrelevant. Surely the Licensee's consultants and/or MeDIFW have both telemetry equipment and expertise. When compared to the search for shore spawning locations, the cost of 40-50 radio tags would be de minimis.

The chance of locating salmon spawning in a large impoundment is extremely unlikely. MeDIFW included shore spawning as a possible secondary benefit of radio telemetry. FERC staff has now become focused on possible salmon shore spawning. While references to salmon shore spawning appear in the references,

the Licensee has failed to provide documentation of wild salmon spawning in a large lakes system with two major spawning tributaries. Furthermore, the success (eggs surviving to young-of-the-year) of such shore spawning events is unknown. It is difficult to imagine salmon spawned along a shoreline surviving an impoundment filled with chain pickerel, smallmouth bass, and yellow and white perch. The study plan as currently presented is unlikely to find spawning activity. The search for shore spawning appears an attempt to "prove a negative".

In rebuffing the use of radio tags, FERC staff ignores one of the primary study goals: (3) document evidence of spawning, e.g., spawning behavior and redd formation. Additionally, FERC staff fails to explain how behavioral aspects of pre-spawning salmon will be described. Impoundment elevation as well as water temperatures may inhabit movement into spawning areas; salmon may stage some distance from the spawning tributary, or move into another basin. Only radio tagging will demonstrate lacustrine behavior, which is the key goal of the initial study proposal.

As the study is now presented, it is simply "window dressing". Nineteen nineties information will be confirmed, and no new information will be provided. The Licensee and MeDIFW will be wasting their resources, resources that could be directed to studies relevant to Licensing issues.

I appeal to FERC staff and ask that they reconsidered the North Twin Tributary access study. Without the inclusion of radio telemetry further study is a waste of resources.

Thank you for the opportunity to comment

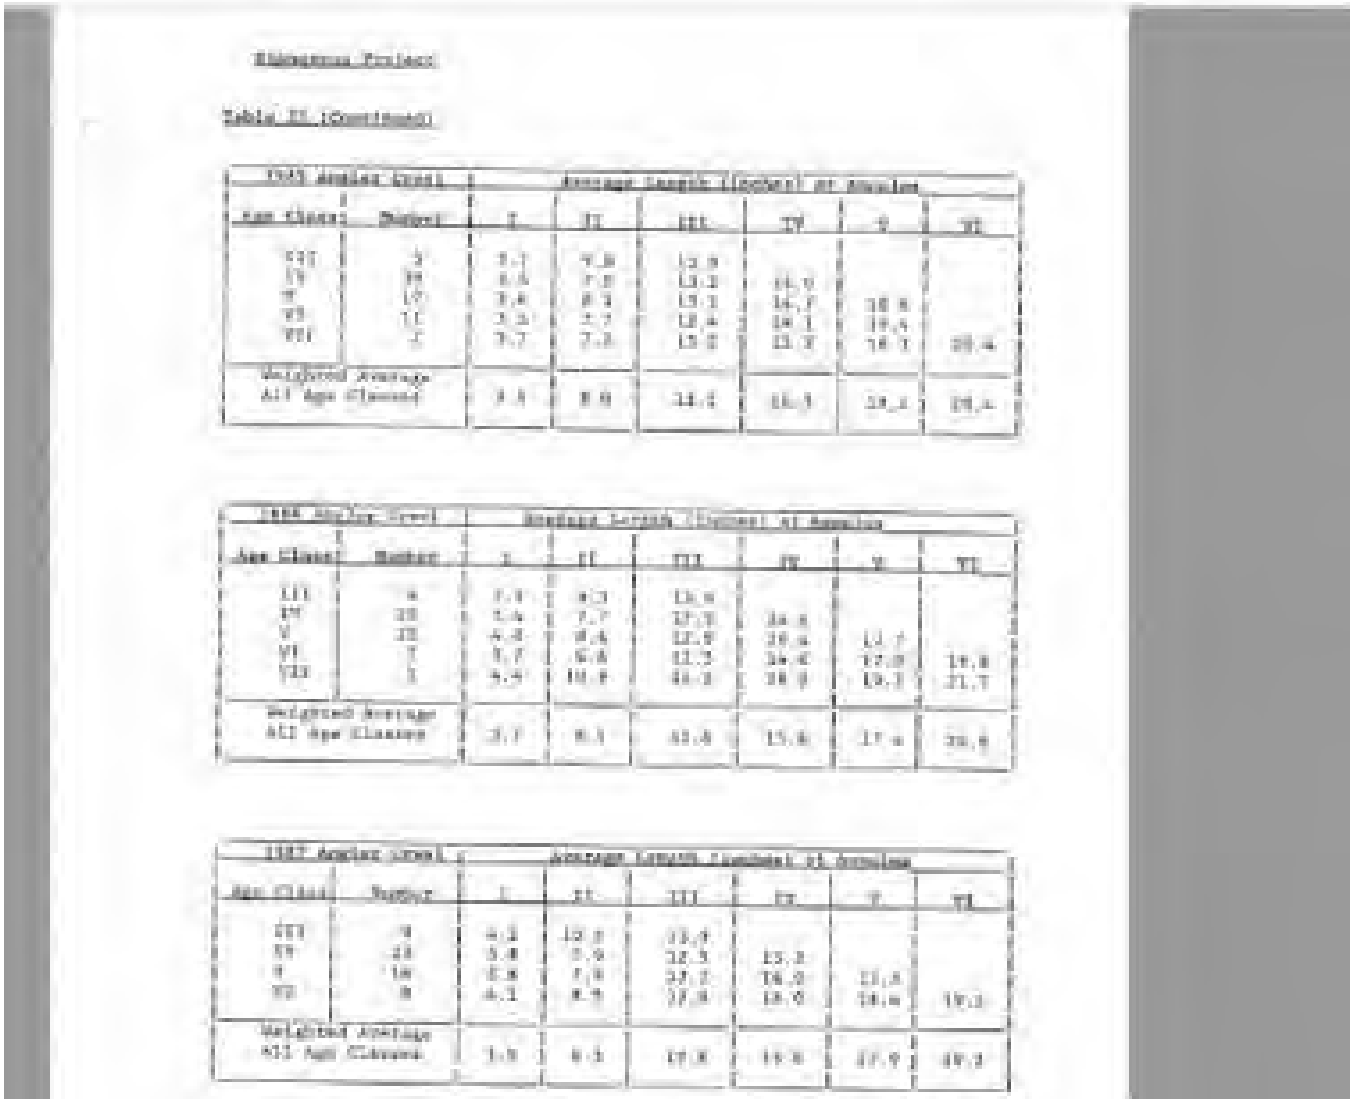
Ms. Kimberly D. Bose September 29, 2023
Secretary
Federal Energy Regulatory Commission
888 First Street, NE
Washington, DC 20426

Dear Secretary Bose, Via Electronic filing

Subject: Ripogenus Project P2572. Submission of Age and Growth Data from Scale Samples Removed from Landlocked Salmon of West Branch of the Penobscot River Angled in Spring of 2022.

The Age and growth data presented below, represents the current (2022) landlocked salmon (salmon) age and growth distribution of West Branch of the Penobscot River (West Branch) in the river reaches downstream of McKay Station. These data were collected from pools just above Nesowadenhunk Deadwater, the major salmon overwintering area. This reach was popular with anglers in the 1980s and 1990s. Sampling location and methods (angling) are comparable to 1980's West Branch angler catch data filed in the 1991 FERC Application shown in the tables below.



Salmon were collected over a four-week period that included nine sampling events (fishing trips) that typically lasted six hours. Salmon were caught by fly and landed using a rubber net, measured and a scale removed from the peduncle area near the lateral line. When obvious, spawning history was noted. The Maine Department of Inland Fisheries and Wildlife read the scales in September. Included in the 2022 sample were a number of salmon less than 14" (the historic legal-size limit), these fish were not included in the table shown below.

| | Landlocked Salmon Great Than 14 inches Angled from the Nesowadenhunk Deadwater Area Spring 2022. Lengths are in inches at the time of annulus formation. | | | | | | | | | |
|---|---|---|---|---|---|---|---|---|---|---|
| | | Number | AGE ! | AGE II | AGE III | AGE IV | AGE V | AGE VI | AGE VII | |
| | IV | 5 | 3.5 | 8.1 | 11.4 | 14.0 | | | | |
| | V | 3 | 3.6 | 7.0 | 10.6 | 12.6 | 14.1 | | | |
| | VI | 6 | 3.2 | 6.4 | 10.7 | 13.5 | 15.0 | 16.4 | | |
| | VII | 1 | 2.7 | 7.5 | 10.0 | 11.5 | 13.2 | 15.6 | 16.9 | |
| | | | | | | | | | | |
| | Average N weighted | | 3.3 | 6.7 | 10.6 | 13.2 | 14.5 | 16.3 | 16.9 | |
| | | | | | | | | | | |

When compared to 1980's salmon growth data (see table shown below), the current (2022) West Branch salmon population has undergone a precipitous decline. Salmon collected in 2022 were typically a year or more behind in growth (rate) when compared to the historic (1985-

1987, Ripogenus Project Application, 1991, Vol. IX) tabular data shown below. This slow salmon growth is most obvious as fish reach their third or fourth growing season and when the absence of suitable food sources, rainbow smelt (smelt) in this case, becomes apparent.

*Ripogenus Application, 1991 Vol IX  Table 37*

Intellectual integrity requires that I note that salmon in reaches e.g., the Lit le  Eddy and Big Eddy, closer to McKay Station are typically  larger (in length) as they are closer to any McKay Station tailwater effects. The upstream tailwater effect is most noticeable on sub adult salmon. However, these “upriver” fish would only have been a small component of the historical data set. The Licensee has, or should have, archival fisheries data sheets and can make statistical comparisons.

The comparison between 2022 and 1995-1997 data demonstrates the diasterous reduction in salmon growth rates brought on by the Licensee’s change in project operations. Smelt, the

primary food source of adult salmon, abundance has declined if not disappeared in recent years. The West Branch is no longer the fisheries FERC described in the Environmental Impact Statement of 1996.

The Licensee has constantly repeated the idea that nothing has changed with the shift to McKay Station peaking operations and earlier impoundment drawdowns. The Licensee has fought all study requests that would provide current fish and aquatic communities data that could be compared to information in the 1991 FERC Ripogenus Project Application. Information presented in this filing demonstrate the fallacy of this pipe dream/negotiating position. Clearly the Ripogenus Project is not meeting MeDIFW fisheries management goals or Maine Department of Evironmental Protection water quality standards.

The licensee's June 2021 Pre-Application Document referenced "data gaps", actually voids, this position remains unchallenged and unchanged. I urge FERC staff to ignore the Licnesee's posturing and require the Licensee to collect information e.g., plankton, smelt spawning success, food requirements, habitat availability (lit oral areas), and downstream smelt drift. This information would provide a description of the existing fish and aquatic communities as well as a course to action that could require modifications of future project operations.

Thank you for the opportunity to present these data.

COVER SHEET FOR FERC EFILING

In Regard to:

Docket # P 2572-133

Dam Relicensing, Great Lakes Hydro America

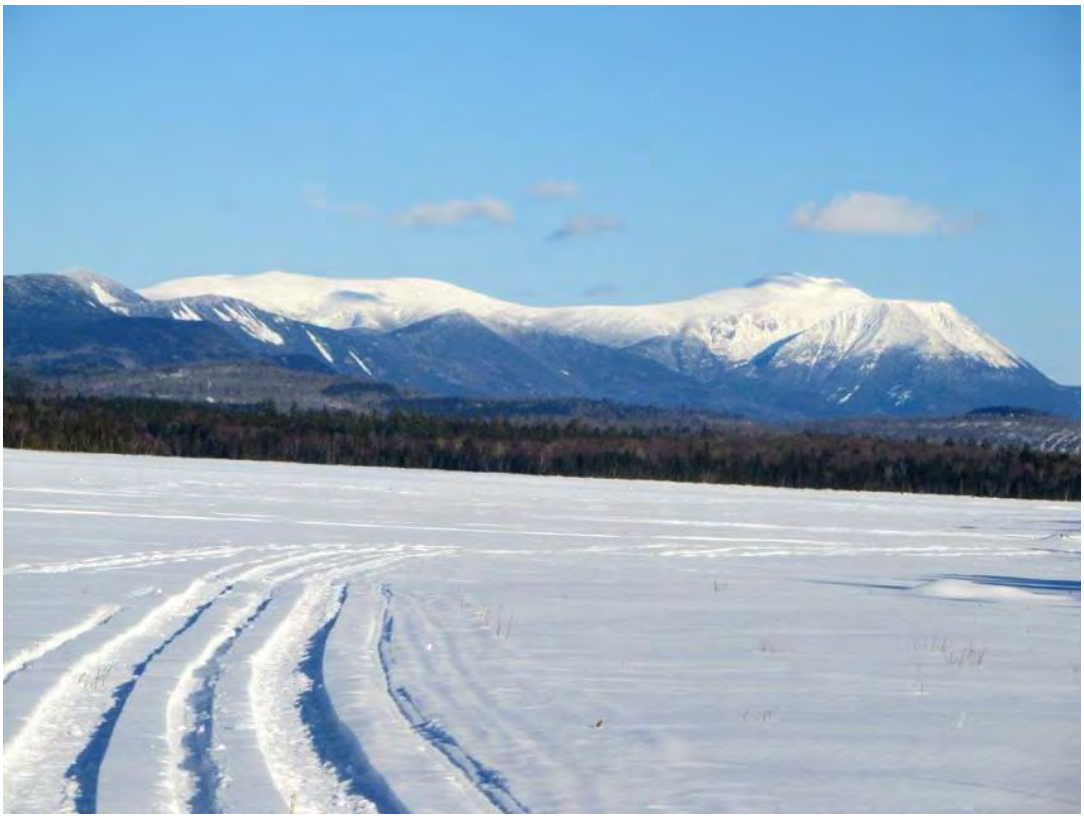
Aesthetics Study

Comments from Jeffrey L Fayle

My name is Jeff Fayle. I was invited to the Aesthetics Study Focus group but am unable to attend due to a moose hunt, so I wanted to share my input with you via mail. I am a member of the Board of Directors of The West Branch Historical Preservation Committee. I am also a Registered Maine Guide, as well as President of the Chesuncook Dam Association since its inception. I've had a camp on Chesuncook Lake for over 60 years.

First, it is clear that this study group should have been formed from the very beginning, as FERC requested. In addition, Kleinschmidt Associates are not the ones who should be choosing what locations get assessed and definitely not the ones doing the assessing. The relicensing is flawed, in that an unbiased entity should have been hired to do the studies. My concern is that these studies may be designed by the licensee to tactically withhold relevant data.

The scoring of the KOP's is unfathomable to me. Every KOP above Ripogenus dam received a "B" grade. How can this be possible when the State of Maine considers these lakes "outstanding resources in need of policy protection"? Yet GLHA rated them no higher than the Ambajesus Wall – which is nothing but a metal wall built alongside a road! These ratings seem absurd to anyone who knows the area and may reflect a distinct bias towards water below Ripogenus. The aesthetics and remoteness of the region are the reasons why the College of the Atlantic, Matagamon Wilderness Base, Outward Bound, Camp Winnebago and many more groups make multiple canoe trips down Chesuncook each year.



Furthermore, please note that "Chesuncook Lake from a boater's perspective" received a Landform score of only 1! Yet it sits at the foot of Mount Katahdin, the tallest mountain in Maine and at the end of the Appalachian trail! How can this possibly be described as "low rolling hills, foothills?"

Chesuncook Boater's perspective also received an Influence of Adjacent Scenery score of 2 as "Somewhat enhances overall visual quality," while the Ambajesus Boat Launch and Ambajesus Wall received a score of 3 as "moderately enhances overall visual quality." Metal walls and boat launches do not enhance visual quality at all, while grand mountain vistas obviously do. The KOP's from a "boater's perspective" in no way capture the visual appeal of Chesuncook, Caribou and Ripogenus lakes. The images chosen don't even include the surrounding mountains such as Big Spencer, the Katahdin range, and the Gorman chairback range.

New locations and scoring must be completed for the boater's perspective on Chesuncook, Caribou and Ripogenus lakes. Remote campsites that include views of the lakes such as Mouser Island, Cardiser and Sandy Point should be included in the second study. Images of the lakes that capture the surrounding mountains must also be included. The study needs to be realistic and honest. Please view the attached photos!

Kimberly D. Bose October 12, 2023
Secretary Federal Energy Regulatory Commission
888 First Street, N.E.
Washington, DC 20426 Via Electronic Filing

Dear Secretary Bose,

Re: The Ripogenus Projects P-2572, Appeals and Requests regarding FERC's September 19, 2023 filing Determination on Requests for Study Modifications and New Studies for the Ripogenus (P- 2572) and Penobscot Mills (P- 2458) Hydroelectric Project

Regarding FERC's September 19, 2023 filing, it is important to point out certain errors and omissions that are central to the Licensee's relicensing efforts. This filing is now part of the record. Several of these comments are patently wrong and need to be corrected.

Rainbow smelt (smelt) are the key environmental issue. Ripogenus Impoundment smelt including their "drift" into the West Branch of the Penobscot River (West Branch) below McKay Station are the central fishery issue. The status of the Project's smelt populations remains undefined and requires lacustrine and riverine studies that would fill these data gaps or voids.

This filing requests that FERC correct the record by removing facts not in evidence and substituting factual information. Once the body of information is reviewed, I ask FERC to reconsider its findings and reverse 1) their position on the current status and availability of smelt in the Ripogenus Impoundment and downstream West Branch and 2) the need for funding of a MeDIFW West Branch creel survey.

FERC policy appears to consider existing environmental conditions as baseline. However, in the (re ) Licensing of the Ripogenus (P- 2572) and Penobscot Mills (P- 2458) Hydroelectric Project FERC has consistently depended on 35–40-year-old data found in the 1991 Great Northern Paper License Application. This action is not FERC's definition of baseline. To further exacerbate the process, the few FERC required studies (Fish Assemblage, Outage Study) along with MeDIFW Ripogenus Impoundment creel surveys and limited smelt drift net samples all demonstrate a system that has significantly declined since 1991. Additionally, the Licensee should be required to defend all its current position that "nothing has changed", including Wes Branch angler use. In fact, historically the projects were operated with steady base flows 24-7. Now the projects are dispatched to follow electric market conditions. The burden of proof should lie with the Licensee to demonstrate otherwise.

The current FERC licensing process appears to encourage Stakeholder participation in this licensing format. However, there is little evidence that stakeholder comments have been thoroughly reviewed, or formal literature citations analyzed and their conclusions accepted or rebutted. I, along with other Stakeholders, put a great deal of efforts into our comments. These comments are intended to provide additional information to the licensing process or request that needed information is provided.

The Stakeholders and, to a lesser degree, the agencies are being treated as second class citizens. Unless comments and study requests reflect favorably on the Licensee's so called data, Stakeholder comments are summarily dismissed. Too often FERC filings accepts the Licensee's positions and views of the existing environment conditions without providing current quantitate information to support their position. A casual reader might surmise that much of FERC's September 19, 2023 filing was a product of "cut and paste" from the Licensee's filings.

The below text outlines the errors and omission found in the Smelt and Creel Survey Studies denial. Explanations are provided, and when possible correct information is also provided

Smelt Study (Request denied)

Background

The SPD included a Fish Assemblage Study of the Ripogenus impoundment and the West Branch downstream from Ripogenus Dam. The SPD erroneously continues "*GLHA conducted the study and documented the presence of smelt in the Ripogenus Impoundment, as well as the occurrence of smelt "drift*" through McKay Station downstream to the West Branch." This statement is incorrect, no studies or study results exist.

In dismissing the Smelt Study request, FERC writes in the September 19, 2023 filing "*Mr. Spear provides similar reasoning on the need here for the smelt study, with little additional support or explanation as to how such a study would inform a licensing decision [sections 5.9(b)(4) and (b)(5)]".* As explain below, this statement is simply wrong as FERC's earlier filings are based on facts (data) not in evidence. Rather FERC used subjective judgement, and the Licensee's faulty assumptions in denying study requests. There were no instances where FERC reviewed any of the multiple references and rebutted the many authors and publications cited. Perhaps even worse, FERC uses legal filing protocols as a reason to dismiss valid claims.

> "*The results of the Fish Assemblage Study, as presented in section 5.0, Results, of Appendix D to the ISR, along with Great Northern Paper's historical sampling* data and

***1)*** *Great Northern Paper's historical sampling data. Maine DIFW's past and on-going smelt "drift" studies are sufficient for an analysis of the effects of project operation on the smelt population in the Ripogenus impoundment and the amount of smelt drift downstream into the West Branch [section 5.9(b)(5)]. There has been no material change(s) in the law or regulations applicable to the information request [section 5.15(e)(1)],*
***2)*** *nor has there been a significant change in the project proposal or*
***3)*** *significant new information material to the study objectives that has become available [section 5.15(e)(4)]."*

1) This reference to 35 year old smelt collection data was well before the Licensee changed project operations to a peaking mode. The fish and aquatic communities that existed 35-40 years ago are not relevant to current conditions brought on by the change in project operations.

   FERC staff writes, "DIFW's past and on-going smelt "drift" studies". Unless used as a term of art, *smelt "drift"* and "*studie*s" are both incorrect and misleading. Based on time available, MeDIFW collected smelt for short periods during 2021 and 2022. Based on conversation with MeDIFW, 2021 smelt drift net sampling occurred on 12 occasions. No smelt were present in one event, and two other events each produced one smelt. If corrected for flow and expanded, the correction factor would be between 50 and 100. As these data are from MeDIFW files, it is appropriate to let MeDIFW continue with any further analysis. In what could be considered deceptive, the Licensee was aware of these 2021 smelt collections and failed to publish them!

2) While MeDIFW deserves full credit for taking the initiative, smelt collections based on the availability of staff, were not studies in the same context or intensity as official reviewed and approved licensing studies. Short term 2021 and 2022 "grab samples" do not qualify as studies. Furthermore, to suggest that they were on par with the GNP studies during the 80s and early 90s is incorrect. In addition, <u>there are no ongoing 2023 smelt studies.</u>

Additionally, FERC writes "*GLHA conducted the study and documented the presence of smelt in the Ripogenus Impoundment, as well as the occurrence of smelt "drift" through McKay Station*". This statement is also wrong. The Licensee never made any direct effort to undertake smelt "collections" and never claimed they did! Smelt collected in the fish Assemblage Study, while insightful, were a bycatch.

3) FERC staff claims there has been no significant change "in the project proposal". In real time they are correct but they fail to mention that the "smelt issue" dates back to filings made in 2021. FERC staff and the Licensee

ignored similar requests made in 2021 and 2022 and now FERC states the request is too late!

3a) Citing chapter and verse, FERC staff claims no new information has become available. Again, FERC staff is simply ignoring the facts. The Fish Assemblage Study found a disproportional number of older, large smelt in the Ripogenus Impoundment. Salmon growth in the Ripogenus Impoundment and downstream West Branch (September 29, 2023 filing, accession number 20230939-5100 ) continues to be below MeDIFW standards. How much new information is needed before the necessary studies are mandated?

Regarding smelt collections FERC Staff claims "appropriate methods have not been described". FERC staff has repeatedly used the term "smelt drift" which implies a tacit understanding of previously described methodology. MeDIFW essentially duplicated GNP's collections methods (the MeDIFW collection site was a few hundred yards downstream) Repetition of smelt collection methods would be redundant but can be easily provided upon request.

FERC staff continues to rely on the underfunded and under staffed MeDIFW rather than the well-funded and well-staffed Licensee for information needed to meet environmental mandates. FERC references MeDIFW smelt studies including unpublished data yet to be provided. No smelt information has been presented, and from conversation with MeDIFW, their time available sampling simply confirmed an occasional smelt drift. The Licensee's statement that the few smelt collected in 2021 and 2022 match abundances described in the 1991 License Application is a gross misinterpretation of information. As noted above, I have seen no MeDIFW "smelt" filings nor I have I seen any smelt drift nets, to date, there is no on-going (2023) smelt study.

FERC continues with a discussion of juvenile smelt life history including prey preferences, plankton. "*Edward Spear states that the smelt information included in the ISR shows a population of larger-sized smelt that are too big to serve as prey for adult landlocked salmon. " Mr. Spear claims that, in addition to cannibalism; reduced abundance of zooplankton; reduced, fluctuating, or lost littoral areas; a reduced volume of water between surface- and deep-water layers in the impoundment (or metalimnion); and turbidity are known factors affecting smelt populations. Mr. Spear recommends that GLHA conduct a smelt study of the Ripogenus impoundment that focuses on spawning, egg survival, fry escapement, zooplankton availability (with an emphasis on rotifers), and survival of smelt through their first year. The goal of this study would be to assess the status of the Ripogenus smelt population by following an age class from egg to*

*Age 1, as well as to determine the contribution, if any, of this cohort to the prey base in the West Branch downstream from McKay Station and the salmonid fishery*"

FERC concludes "*Mr. Spear provides similar reasoning on the need here for the smelt study, with little additional support or explanation as to how such a study would inform a licensing decision [sections 5.9(b)(4) and (b)(5)*". FERC's denial of this phase of the smelt study repeats the Licensee's erroneous assumption that the Ripogenus smelt population is providing the needed salmonid smelt forage base. There is simply no information on the health (condition, K-Factor) and status of the downstream West Branch salmon population. The apparent decline in the Ripogenus smelt population is an impact of current Project operations.

FERC's total avoidance of any smelt studies recommendation is even more profound given studies required at Aziscohos Hydroelectric Project, FERC No. 4026. This study focused on Smelt access and success of spawning during spring refill at Aziscohos Lake and in the process identified smelt egg siltation issues. Umbazookas Stream flows into a large embayment. Deer and Brandy Pond inlets are also associated with shallow embayments that would be vu*lnerable to siltation during refilling.* I fail to understand the differences and importance of salmonids and smelts in these two impoundments and why one study is being conducted and the other denied.

FERC continues "*with little additional support or explanation as to how such a study would inform a licensing decision"*. The answer is both obvious and quite simple. Once the problem(s) with the smelt population(s) is/are identified, corrective measures e.g. drawdown limits and timing, can be prescribed. Without any current information, the Licensee has made far-fetched statements regarding fish and aquatic communities that FERC seems to accept at face value. The health and abundance of smelt is of primary importance to the project's salmonid fisheries and the 1996 Environmental Impact Statement discussed the salmon/smelt relationship. MeDIFW has indicated that there are insufficient smelt to feed the Ripogenus Impoundment salmon population. It seems the burden of proof regarding smelt and other aquatic communities lies with the Licensee. Thus, how can FERC staff make an informed decision without data? If FERC staff agrees that project operation has decimated the Ripogenus juvenile smelt population they should say so.

In summary, FERC statements concerning on- going MeDIFW studies are incorrect. There are no ongoing studies. There are NO current or recent quantitative data on the Ripogenus smelt population and downstream smelt drift. If fact, other than the few Ripogenus impoundment smelt collected in the fish assemblage study, there are no smelt data.

Creel Survey (Denied)

Comments on the Requested Study

Clearly FERC has the authority to deny any study requests. However, I take issue with their interpretation of MeDIFW's comments and their understanding of what an angler creel survey entails. Equally clear is that MeDIFW policy mandates creel surveys. From the INLAND FISHERIES AND HATCHERIES STRATEGIC MANAGEMENT PLAN 2021–2035. Landlocked Atlantic Salmon, *Goals, Objectives & Conservation/Management Strategies "Reevaluate salmon waters that haven't been recently assessed to ensure existing regulations reflect current management goals and angler behavior"*

A census is defined by Merriam-Webster as " *a usually complete enumeration of a population where information is collected"*. Angler survey boxes do not meet this definition. FERC does not seem to understand the difference in the "fisheries management" level of subjective information collected as opposed to a creel survey where quantitate data are collected. Fisheries management includes a number of measures including the passive, "no action" option. Spot fish collections, mail surveys, or angler complaints, none involving large, if any data sets, can result is management changes. The licensing process requires current data rather than an overview, subjective judgement or the use of 35-40-year old data. The recreation survey is simply "window dressing" and will provide no quantitative data.

FERC writes "*In its comments, Maine DIFW provides its rationale for not requesting clerk angler surveys as part of the relicensing. The reasons include: (1) the need for consistency and repeatability in survey methodology; (2) the availability of ample, recent angler survey data from summer and winter 2021 collected by Maine DIFW; (3) the fact that Maine DIFW has the information currently needed to assess the fishery and respond with management changes, as necessary; and (4) plans by Maine DIFW to survey the Ripogenus Project and the West Branch in 2025"*

1) FERC cites MeDIFW comment "*the need for consistency and repeatability in survey methodology"* as a reason for denial of the creel survey study request. This request clearly stated that it would be conducted by MeDIFW following their protocols In this case FERC's objection is a circular agreement and unrelated to my initial request. Furthermore, If "*repeatability*" is the criterion there would be few creel surveys; a one year creel survey is not unheard of. Should 2024 creel survey result in angler use and catch numbers similar to those found in the 1991 License Application, additional study years would not be required.

2) FERC misinterpreted MeDIFW's comments that clearly indicated they would conduct a West Branch creel survey if funding and staff became available. There are no current angler creel census data. Angler survey box results do not qualify in a

thirty-year Licensing event. MeDIFW wrote extensively that they lacked funding and staff. MeDIFW has no venue where they can directly ask for funding. However, the connotation of their statements is clear; they want to conduct a West Branch creel surveys ….in house.

A simple test of the above would be to offer MeDIFW funds to staff a West Branch survey clerk as well as transportation costs. MeDIFW acceptance or denial of the "offer for funding" would be conclusive.

3) There is "*availability of ample, recent angler survey data from summer and winter 2021 collected by Maine DIFW;"* FERC included one item (Ripogenus 2021 summer and winter data) that is true and couples it to a falsehood (implied reference to West Branch angler creel survey information). While there is 2021 Ripogenus Impoundment winter-summer survey data, that is irrelevant to the question at hand: what is the daily West Branch summer angler, use and catch? There is no West Branch creel survey data as angler creel survey boxes are simply no substitute for face-to-face methods that produce quantitative results. Furthermore, if MeDIFW has provided the Licensee with angler information other than from the biased "angler survey boxes", this information needs to be provided to the stakeholders

I urge FERC Staff to disregard the baseless fish and aquatic communities' information continuously presented by the Licensee. This phase of the Licensing process is intended to collect information. The Licensee has fought all stakeholder efforts to collect quantitative fish and aquatic communities' information. The Licensee is attempting to describe the Ripogenus Project fish and aquatic resources in a fanciful manner that cites 35 year-old data along with the gross misuse of MeDIFW data. FERC continues to avoid addressing the litany of valid complaints developed by the stakeholders and resource agencies. Archival 35-year-old Information provided by the Licensee will be of no use to FERC staff when competing uses and balancing of resource needs to be considered.

The above comments reflect my concerns with fish and aquatic communities, and angler information provided by the Licensee. The requested information will become the base of the Stakeholder case as we move forward in this complicated process. Thank you for your patience and the opportunity to comment.

Kimberly D. Bose October 13, 2023
Secretary Federal Energy Regulatory Commission
888 First Street, N.E.
Washington, DC 20426 Via Electronic Filing

Dear Secretary Bose,

RE: Project No. 2572-136 FERC August 22, 2023 response regarding October 2021 to April 2022 Flow Deviations, and Allegations of June and October 2022 Flow Deviations and Stranding Effect

FERC's August 22, 2023 well-reasoned response to Article 402 multiple 2022 low flow events ignores the clear violation of Article 406 flow requirements. As required by Article 406, the Holbrook Bypass Channel is a critical enhancement measure designed to support the continued repopulation of the West Branch of the Penobscot River (West Branch) Landlocked salmon (salmon) population. Both outage and low minimum flows have eliminated fisheries benefits provided for by Article 406. While outage flows are beyond the Licensee's control, West Branch minimum flows are the sole responsibility of the Licensee.

The Holbrook Bypass Channel (Bypass Chanel) was designed to provide flows based on Great Northern Paper production power needs; relatively stable base flows, typically 2500 cfs. Peaking flows were unforeseen. As a matter of physics, when the Licensee reduces McKay Station outflows, inflow to the Bypass Channel is reduced. At 1100 cfs all enhancement measures are lost. The Licensee controls McKay Station flow and bares total responsibility for reduced operating flows. FERC failed to fully acknowledge or prescribe remediation to this ongoing problem.

FERC's only comments regarding the Holbrook Bypass Channel were a quote from my May 31, 2022 filing, and one found in Fish Stranding Study section: "There was no change in water elevation in the Holbrook Side Channel". Without baseline information e.g., flow and elevation data, this comment is meaningless. In short, FERC failed to clearly identify and deal with low/lost Holbrook Bypass flows during outage and minimum flow events and the concurrent loss of juvenile salmon production.

FERC's filing demonstrates that they understand the impacts of low flows on the West Branch fish and aquatic communities in the main channel. However, understanding Article 406 is equally important. McKay Sation flows below approximately 2200 cfs result in the failure to meet the 35 cfs Holbrook Bypass summer flow requirements that are provided

by one of two gates. Low McKay Station outflows compromise all Bypass Channel juvenile salmon production goals. During outages or the 1000 cfs minimum flow, any enhancement is totally lost as the Bypass Channel dries up.

FERC references Standard Article 15, that in part states " *… the licensee shall, for the conservation of development of fish and wildlife resources... comply with such reasonable modifications of the project structures and operation, as may be ordered by the Commission upon its own motion... after notice and opportunity for hearing.....*" While this statement was in the context of Ripogenus Dam gate modifications needed to meet emergency flow needs, it applies equally to Article 406, the Holbrook Bypass Channel. Both License Articles are equally important. A change in the existing McKay Station minimum operating flow from 1000 cfs to 2000-2200 cfs would provide critical additional protection. Development of a method or methods to open the second Bypass Channel gate could also provide emergency flow during low flow periods.

When the stakeholder identified the impacts of McKay Station outages, FERC quickly responded. The August 22, 2023 filing requested development of interim protection measures in the event of McKay Station outages. When implemented, these flows will reduce stranding. In addressing the lost enhancement measures intended by Article 406, I urge FERC to act in a similar manner. The West Branch salmon population can not withstand another two to three years of lost juvenile production.

Thank you for the opportunity to comment.

William Cushing, Millinocket, ME.
To whom it may concern,

My name is William Cushing. I represent Andre Emerson Cushing Corporation ("AEC"). AEC is majority owner in T3-R12 WELS ("312"). 312 Comprises 80% of Ripogenous Lake and nearly 20% of  Chesuncook Lake, with shorefront from Holmes Hole on the eastern shore of Chesuncook down around the southern end and then back up to Caribou Point to the west. 312 Has been a part of our family timber holdings for 153 years. I have been on Chesuncook Lake since 1964. For the last 13 years, I have lived nearly year-round in the camp my grandfather built in 1954 on Ripogenus Lake.

From an aesthetics perspective: it has come to my attention that the Kleinschmidt/Brookfield assessment of the view shed at Chesuncook Lake is being compared to Dolby Pond and Ambejesus Lake. This leaves me quite incredulous. First, Dolby Pond and Ambejesus Lake are "in-town" bodies of water. Ambejesus Lake is typical a typical "camp lake," as the camps are side by side by side like on Smith Pond or any other pond easily accessible from town. Dolby Pond is a stump field with a few feet of water in it, and is designated as a pond.

Chesuncook is a completely different animal. First, we are 30 miles in on the Golden Road. We are smack in the middle of the largest timber basket in the Lower 48 States at 9,000,000 acres.  And we are talking about the Allagash Wilderness Waterway. Chesuncook is the gateway to the Allagash Wilderness Waterway. This waterway is one of Maine’s crown jewels, with all of God’s creatures and everything that grows on display for all to see. The waterway is known all over the globe and is visited by people from everywhere. We are also talking about H.D. Thoreau. This is the land he wrote about and made famous to the world. The view shed here is peerless. Chesuncook runs parallel to the Katahdin Range. From one end of the lake to the other, you run right alongside the entire range, with perspectives only attainable by boat or air. We are remote, but once here, the experience is something every visitor carries with them for the rest of their days. You just cannot say that about Dolby Pond.

I hope this clears up any questions you may have about the Chesuncook area. I hope that Kleinschmidt/Brookfield, moving forward, engage with honesty and integrity with those who live in thrive here in the Northwoods, as we are still waiting for the recreational study that they were reminded of back in May.

I would also like to take this opportunity to invite the FERC representatives to come and visit us.  I would be happy to host lunch and take the representatives on a boat tour of the lake in the spring/summer of 2024. I hope it’s an offer you can’t refuse.

Thank you for your attention,

William Cushing
Director
Andre Emerson Cushing corp.

Washington, DC 20426

**Subject:** **Ripogenus Hydroelectric Project (FERC No. 2572-133)**
**Penobscot Mills Hydroelectric Project (FERC No. 2458-247)**
**Notice of Operations Model Technical Workshop**

Dear Secretary Bose:

Great Lakes Hydro America, LLC (GLHA), Licensee of the Ripogenus Hydroelectric Project (No. 2572) and the Penobscot Mills Hydroelectric Project (No. 2458) (collectively referred to as the "Projects"), herein is providing notification of the date and location for the upcoming Operations Model Study Technical Workshop to be hosted by GLHA.

**Background**

On June 11, 2021, GLHA filed the Notices of Intent and a Pre-Application Document (PAD), which initiated the formal relicensing proceeding to obtain two separate new licenses for the continued operation of the Projects through FERC's Integrated Licensing Process (ILP). On March 23, 2022, GLHA filed the Revised Study Plan (RSP), and on May 13, 2022, FERC issued the Study Plan Determination (SPD). Pursuant to the RSP and as approved and modified by FERC's SPD, GLHA performed first season study activities in 2022 with available results provided in the Initial Study Report (ISR) filed with FERC on April 24, 2023. Subsequent to filing the ISR, stakeholders filed comments on the ISR and new study requests, and on September 19, 2023, FERC issued the second SPD.

**Operations Model Technical Workshop**

Pursuant to the RSP and FERC-issued SPDs, GLHA developed an operations model designed to evaluate alternative operating scenarios in support of the ongoing relicensing of the Projects. During the May 2, 2023 ISR Meeting, GLHA described how the operations model was developed, calibrated, and verified.

Building off the information presented during the ISR Meeting, GLHA will be hosting a 2-day, ***in-person*** Operations Model Technical Workshop. The purpose of the workshop is to further explain the model inputs, calibration, and verification. During the workshop, GLHA will describe how the model is being used in support of the relicensing, how to request alternative operating scenarios, and how to interpret the model results. All stakeholders interested in learning more about the operations model are invited to attend this workshop.

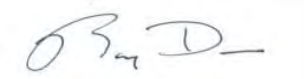
**GREAT LAKES HYDRO AMERICA, LLC**
1024 Central Street, Millinocket, ME 04462
T +1 207.723.4341 F +1 207.723.4597 brookfieldrenewableUS.com

The workshop will be held ***in-person*** at the GLHA's Office located at 1024 Central Street in Millinocket, Maine 04462 over two consecutive days, on December 5-6, 2023.

In order to plan accordingly, GLHA respectfully requests stakeholders who plan on attending the workshop RSVP by contacting Cate Russell at Cate.Russell@hdrinc.com or (207) 239-3792 at your earliest convenience but no later than November 28, 2023.

The anticipated agenda for the workshop is provided below.

**Tuesday, December 5, 2023 (9:00 AM to 4:00 PM)**



1. Logistics, Safety, and Introductions (9:00 – 9:15)
2. Meeting Purpose (9:15 – 9:30)
3. Relicensing Schedule (9:30 – 9:45)
4. Overview of Projects (9:45-10:30)
5. Overview of the Operations Model (10:30 – 12:00)
6. Lunch (12:00 – 1:00)
7. Model Hydrology (1:00 – 1:30)
8. Model Verification (1:30 – 2:00)
9. Overview of Model Interface and the Operations Baseline (2:00 – 4:00)

**Wednesday, December 6, 2023 (9:00 AM to 12:00 PM)**

1. Overview of Requests for Alternative Operating Scenarios (9:00-10:00)
2. Overview of Interpreting Model Run Results (10:00-12:00)

If you have any questions regarding this information, please contact me by phone at (207) 775-5605 or by email at randy.dorman@brookfieldrenewable.com.

Sincerely,

Randall Dorman, Licensing Manager

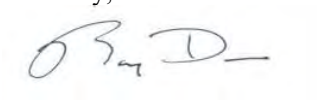
Kimberly D. Bose, Secretary
Federal Energy Regulatory Commission
888 First Street, NE
Washington, DC 20426

**Subject:** **Ripogenus Hydroelectric Project (FERC No. 2572-133)**
**Penobscot Mills Hydroelectric Project (FERC No. 2458-247)**
**Fourth Study Progress Report**

Dear Secretary Bose:

Great Lakes Hydro America, LLC (GLHA), Licensee of the Ripogenus Hydroelectric Project (FERC No. 2572) and the Penobscot Mills Hydroelectric Project (FERC No. 2458) (collectively referred to as the "Projects"), herein files with the Federal Energy Regulatory Commission ("FERC" or "Commission") the Fourth Study Progress Report for the relicensing of the Projects. The Projects are located on the West Branch of the Penobscot River and Millinocket Stream in Piscataquis and Penobscot counties, Maine.

The current licenses for the Projects were issued on October 22, 1996 and expire on September 30, 2026. On June 11, 2021, GLHA filed the Notices of Intent and Pre-Application Document, which initiated the formal relicensing proceeding to obtain two separate new licenses for the continued operation of the Projects through the Commission's Integrated Licensing Process (ILP). On March 23, 2022, GLHA filed a Revised Study Plan (RSP) for the Projects, and the Commission issued the Study Plan Determination (SPD) on May 13, 2022. GLHA performed first season study activities in 2022 with available results provided in the Initial Study Report (ISR) filed with FERC on April 24, 2023. Subsequent to the filing of the ISR, stakeholders filed comments on the ISR and new study requests, and on September 19, 2023, FERC issued the second SPD.



Pursuant to the RSP, GLHA herein submits the Fourth Study Progress Report for the period from August 1 through October 31, 2023 for the Projects. The enclosed table (report) provides a list of the required studies and associated status of progress, as well as any modifications to the approved methodologies.

Concurrent with this filing, GLHA is providing a copy of this letter to all parties listed in the attached distribution list. A copy of the Fourth Study Progress Report can be downloaded from FERC's eLibrary system at https://www.ferc.gov/docs-filing/elibrary.asp by conducting a search using the docket numbers p-2458 and/or p-2572.

| 6 | Upstream American Eel Passage Assessment Study | • First season study activities were completed as required in 2022 with study results provided in the ISR.<br>• Based on comments received during the ISR Meeting and the FERC SPD issued on September 19, 2023, GLHA performed nighttime eel observations and electrofishing surveys at the Dolby, Millinocket, North Twin, and Millinocket Lake Storage Developments.<br>• From mid-July through September 2023, approximately 5-7 nighttime eel observation events were conducted at each dam .<br>• In July/August 2023, one nighttime electrofishing survey was performed downstream of the Millinocket, North Twin, and Millinocket Lake Storage dams. Due to high water conditions throughout the late summer and fall, after consultation with USFWS, MDMR, PIN, and MDIFW, further attempts to conduct additional electrofishing surveys were suspended in October.<br>• Data collected in 2023 will be provided in the USR. | • Heavy precipitation and unit outages experienced during the summer of 2023 resulted in high flows in the rivers and spill conditions at the dams limiting the ability to perform nighttime eel observations and electrofishing surveys. Although there were fewer surveys than anticipated, the monitoring completed in 2023 allowed GLHA to gain a good understanding of juvenile American eel presence and behavior at the Penobscot Mills Project. |

Kimberly D. Bose November 6, 2023
Secretary Federal
Energy Regulatory Commission
888 First Street, N.E.
Washington, DC 20426 Via Electronic Filing

RE: Harrington Lake (P- 2634) and Ripogenus Hydroelectric Project (FERC No. 2572-133) Penobscot Mills Hydroelectric Project (FERC No. 2458-247) April 24, 2023 initial Study Report, Appendices A and B.

Dear Secretary Bose,

The Operational Model Study Report included an analysis of Harrington Lake and its contribution of storage to the above referenced projects. The reference to Harrington Lake and store and released operations revealed a glitch in the 2004 Licensing of the Storage Project (P-2634). This filing seeks to migrate this error by requesting that Great Lakes Hydro America (Licensee), US Fish and Wildlife Service, Maine Department of Fisheries and Wildlife and/ or FERC act together or independently to provide fish passage from Duck Brook into Harrington Lake. As explained below this action is time critical.

Great Northern Paper Company (the former License holder) filed the Storage Project Application for a new License on April 28, 1998. That eventually included the abandonment of five unlicensed storage ponds. Harrington Lake was one of the five impoundments, and historical fish passage issues were eliminated by removal of existing gates.

> By letter dated July 10, 2000, GNE notified the Commission that it had ceased operations at Dole Pond, Long Pond, Harrington Lake, Penobscot Lake, and Loon Lake by removing the gates and associated lifting structures. GNE states that the outlet stream flows and pond water levels would fluctuate naturally with no impounding or flow management. Dole Pond and Long Pond were operated as store and release facilities.

During 2004 the Storage Project Licensing proceeding evolved into a Setl ement Process. The results of this event were the five unlicensed Storage Project facilities were included in the new license as environmental enhancement measures. Apart from Loon Lake, dam gates were replaced. The “unlicensed” projects became part of the new FERC Storage Project License. Operations reverted to a store and release, with targeted minimum flows, with the impoundment drawdowns around early November.

Historically Harrington Lake supported a Landlocked salmon (salmon) fishery that produced a high-quality fish supported by natural reproduction (wild fish). Recruitment of juvenile salmon was virtually entirely from Duck Brook (AKA Ripogenus Stream), the outlet of

Harrigton Lake. Under historical operation, the Harrington Facility was operated as “store and release”. Upstream fish passage was available once the gates were open and the lake drawn down occurred. Annual salmon recruitment was variable and dependent on downstream storage needs that resulted in early Harrington Lake drawdowns. With the 2004 License changes, “poor fish passage” has become no upstream fish passage. The November drawdown regime (after the biological active season) eliminated any reasonable hope of juvenile salmon recruitment to Harrington Lake.

The old wooden Harrington Lake Dam was rebuilt in the 1980’s. As future fish passage needs were uncertain, the new dam was designed and built with a space for a fishway. This space can easily be retrofit ed as a traditional fishway. However, current fishery needs can be met by inserting a Steep Pass Fishway such as is used at nearby Nesowadenhunk Lake. While not an engineer, I believe that the Steep Pass Fishway is the least cost option and quickest method.

The lack of a Harrington Lake Fishway is the type of oversight that happens when well intended people rush to come to consensus. It is my hope that one or all the named parties can quickly resolve this issue. A salmon’s life cycle is five to six years, thus it will take time to reestablish the Harrington Lake/Duck Brook salmon population.

Thank you for the opportunity to bring at ention to this glitch to those involved in the current Licensing of the Ripogenus and Penobscot Mills Projects. Nothing in the above is intended to suggest any error or wrongdoing by any party.

RE: Ripogenus Hydroelectric Project (FERC No. 2572-133) Penobscot Mills Hydroelectric Project (FERC No. 2458-247) Notice of Operations Model Technical Workshop

Dear Secretary Bose,

Unfortunately, I will not be able to at end the Operation Model workshop. My questions and comments are provided in the text below. In my earlier filing I requested an independent peer-reviewed water management or operational study. HRC's Operations Model dated April 24, 2023, represents a great deal of work, doomed to failure as the result of flawed goals and data proved by the Licensee. Nothing I have reviewed has changed my opinion. In fact, the text and tables of Appendices A and B have reinforced the need for an independent study.

Beginning on October 8, 1977, and continuing into 2004 my primary task as a Great Northen Paper (GNP) fisheries biologist was the study of the fisheries and anglers of the West Branch of the Penobscot River drainage. I was tasked with data collection and report writing for the Big A, Ripogenus, Penobscot Mills and Storage Projects. It is unlikely that anyone has boated, waded, walked, or studied the history of these facilities more often. Regarding fish and aquatic communities relating to flow and impoundment elevations, I ask FERC to take these comments as expert testimony.

The 1996 Ripogenus and Penobscot Mills Projects FERC Licenses were based on a Water Management Plan that included Rule Curve operations. It appears that the present Licensee discarded this plan as it does not meet the current energy market driven peeking operations. The Operations Model is based on assumptions and facts not in evidence; with a designed end point that allows the continuation of market driven peaking energy production. However, the Operational Model's most obvious and major flaw is that it totally ignores Ripogenus Project Article

406, juvenile Landlocked salmon (salmon) production in the Holbrook Bypass channel (Bypass). This enhancement was designed to operate when McKay Station flows were in the 2500 cfs range. As McKay Station flows are reduced Bypass flows are also reduced. Beginning with flows in the 2000 cfs range, salmon habitat is reduced; by 1300 cfs juvenile salmon habitat is lost.

The History of Great Northen Paper Water Management

As generating and papermaking technology were improving in the 70s and oil prices rising, GNP became more aware of the need to maintain its year-long hydro-electric capabilities. Stone and Webster conducted the earliest storage studies. During the late 1980s Northrop, Devine and Tarbell (NDT) were tasked at looking at the (combined) Storage Project (four Licensed impoundments along with six[1] unlicensed facilities) and its contribution to the system wide water budget.

NDT started with the assumption that water held in the Storage Projects was only of value when Ripogenus was a full Pond (elevation 941.6). In a fisheries capacity, I at ended meetings and reviewed NDT drafts. The results revealed that on average the combined contribution of licensed and unlicensed storage impound was approximately 4-5 BCF and that the small acreage “unlicensed” impoundments had de minimis value. This led to abandonment of these small storage ponds related to “hydro” needs. During the Set lement Process of the Storage Project (P-2634), many of these small ponds were converted to meet environmental goals. The Licensee now takes advantage of storage at the time of winter gate setting, typically November 1st.

During the early 1990s and in conjunction with ongoing Storge Project Licensing and the Licensed Ripogenus and Penobscot Mills Project, GNP hired Nathen Burris a well known hydrologist (he developed a water management plan for Israel) from the University of Arizona. Professor Burris, using thirty years of flow and storage records developed a water management plan based on Rule Curve needs. This plan met Paper Mill production, environmental, and recreation needs. Professor Burris’s plan became the foundation of today’s FERC Licenses. As with much of flow, pond elevation, fisheries and aquatic communities, and boating needs, neither the agencies, NGOs, nor GNP foresaw market driven peaking operations.

[1] At that time the Umbazookas facility was operated as storage pond rather than a part of Ripogenus Project wetlands mitigation measures.

Both the NDT and Professor Burris studies were GNP work products. The Licensee certainly has copies of these reports and accompanying flow and elevation data. These data should have been included in the operational model. The Licensee should make these reports available.

Current inflow in the Ripogenus

As explained above five unlicensed storage ponds were abandoned as they simply provided de minimis benefits to downstream generation. However, as part of the 2004 Storage Project Set lement Agreement, abandoned facilities were modified to provide environment enhancements, wetlands, and streamflow augmentation. The threefold increase in wholesale energy prices has increased the Storage Project value proportionally. To paraphrase current Storage Project (P2634) licensee requirements;

1) During the spring runoff period, the lake will be filled or near full
2) After July 15, impoundments, when applicable, can be gradually drawndown
3) Various minimum flow requirements are mandated.

Balancing maintaining full pond elevations against instream flow needs is challenging. It appears that the Operations Model default goal was reducing spill and maintaining Storage Project impoundment elevation at the expense of stream flow.

General comments Appendix A

HCR's model appears set to avoid spillage events. Spillage reduces/eliminates recreational activity as well as generation (tailwater elevations). However, it should be noted that occasional spill events are "biologically favorable" as the river bot om is purged of "fines" and sediment.

As there is no other option, HDR model uses existing license required environment minimum/target flows. It appears from the verbiage that alternate minimum flows and target Lake elevations can be added/adjusted.

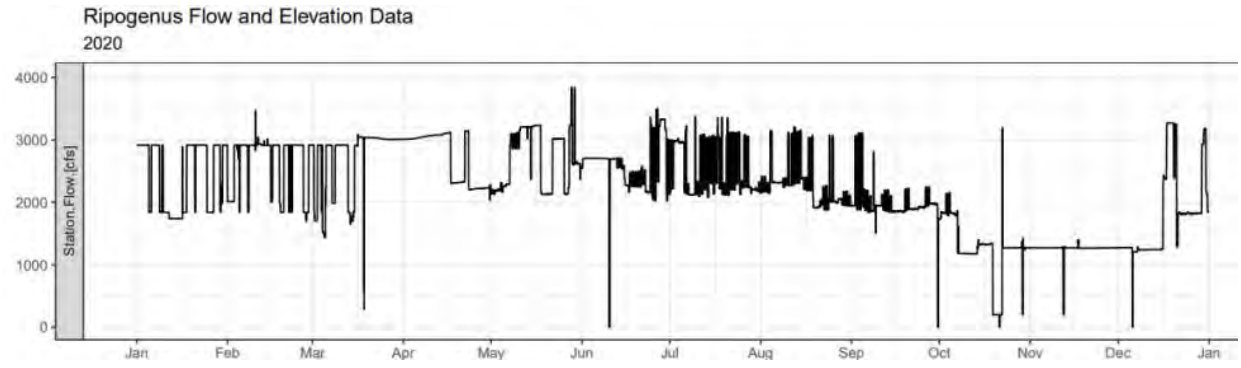
Appendix A: 5.1.1 Historic Operations Data Assessment Study. *The 1991 Water Use Plan (i.e., the licensee's proposed operation alternative) was developed prior*

*to issuance of the Projects' existing licenses and was the basis for the operational requirements included in the Projects' 1996 FERC Licenses. However, as compared to the Water Use Plan, the Projects' current operations are defined by the requirements of the Projects' licenses. Therefore, the 1991 Water Use Plan is not a "management plan" consistent with other management plans resulting from a relicensing proceeding. The one exception being that the Water Use Plan is used as the basis for determining recreational flows from McKay Station at the Ripogenus Project.*

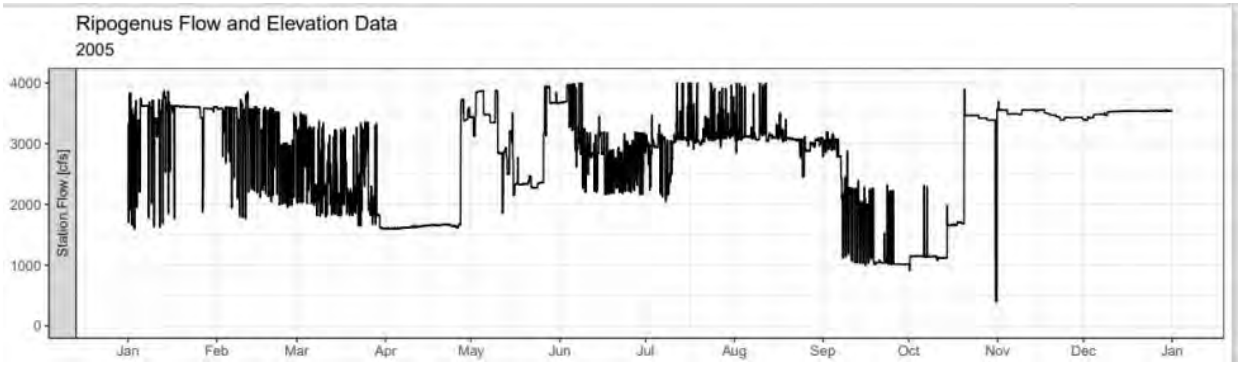
The above is revisionist history. The 1991 Water Use Plan (WUP) and accompanying Rule Curve Operation became the foundation of the 1996 License. The WUP was viable to the agencies and FERC at that time and remains valid today. It is simply the Licensee's opinion that the "*Water Use Plan is not a "management plan" consistent with other management plans resulting from a relicensing proceeding."* The Licensee's desire to change operations to a market driven peaking mode conflicts with environmental, recreational and aesthetic requirements, thus the existing WUP must be defeated, and a new plan installed. The operational model is an at empt to justify the gross shift in power generation from relatively stable base flow to peaking needs.

5.4 Recent Hydrology and Effects on Project Conditions

"*GLHA calculated inflows to the Ripogenus Project based on outflows from the Ripogenus Project in relation to storage in the impoundment to determine water year type (i.e., dry, normal, wet) from 2001-2022 (Table 12). Outflows from the Ripogenus Project are estimated based on gate discharge curves and a calculation of flow through the powerhouse based on generation output. Additionally, the methods used to estimate outflows have varied over time since 2000 based on available technology, project ownership, and other factors. The results of the calculated inflows to the Ripogenus Project were also compared to the hydrology recorded at the U.S Geological Survey (USGS) Gage No. 01029500 located on the East Branch Penobscot River at Grindstone".*



The report states *"Outflows from the Ripogenus Project are estimated based on gate discharge curves and a calculation of flow through the powerhouse based on generation output*. The North Branch begins at Big Bog where it flows westward and is joined by Dole Brook (two dams are located on Dole Brook). The Licensee



continually refuses to use the dam free North Branch USGS records. Moreover, according to the Licensee, HRC's use of USGS's Grindstone flow records that involve several Dams and the use of Allagash drainage (Lock Dam diversion of St John River water to the Penobscot) waters is Ok! There is no mention of the McKay outflow and Grindstone flows comparison other than the two driest years 2001(Grindstone) and 2022 (West Branch) differed. Perhaps a graphic presentation would be appropriate. The use of North Branch USGS records is even more appropriate.

5.5.3 Ripogenus Project
5.5.3.1 Project Operations

"The Ripogenus Project operates as a store-and-release development"

At best, this statement is misleading. In recent years the project has been operated in a peaking mode to meet market driven energy demands. The tables below are quite descriptive of McKay Station peaking operations.

Appendix A 32 Additionally, "*at times, flows from the Ripogenus Project are needed to maintain the required impoundment elevation at the North Twin Development when inflows (via tributaries or the Millinocket Lake Storage pump station) to the North Twin Development are less than the required minimum flows from the North Twin Development (i.e., approximately 2,000-3,000 cfs to meet the minimum flow requirements in the lower West Branch and mainstem Penobscot River for the protection of fisheries and aquatic habitat*)."

In general, the above statement is incorrect. The Penobscot Mills Project minimum flow is 2000 cfs (3000cfs August 22-Oct 15). Except for extreme drought, the combined "normal" McKay Station flows (2200 -2500 cfs), Millinocket Lake Pump Station, and tributary inflows are more than adequate to meet Licensed Penobscot Mills flow needs. The Licensee has complete control of Penobscot Mills flow. Should the Licensee continue their peaking operations, then low North Twin Impoundment elevations are their responsibility and not an excuse to drain the Ripogenus Impoundment. The West Branch reaches below McKay Station also require the "protection of fisheries and aquatic habitat."

Appendix A 60. *The spring runoff is used to replenish storage in the impoundments. Water is withdrawn at a controlled rate from the storage impoundments during the entire year to provide maximum sustained base-load energy in accordance with the system-wide rule curve, to provide storage capacity for the next spring, and to meet other constraints of the system*.

Unless the Licensee is violating the Storge Project (P-2634) License, this statement is incorrect. The Storage Pond License (see above excerpts) requires holding storage pond evaluations to at or near full pond until July 15$^{th}$ for shorebird nesting. Thus, there are no "controlled" or other drawdowns from the Storage Project until July 16$^{th}$.

"*Because the Projects operate as a system, there is no Project-specific rule curve for the Projects; rather the Projects are operated using a system-wide rule curve. The amount of available storage within the storage system is monitored continuously and operation of the entire system is adjusted, as necessary, to maintain overall storage conditions within proximity to the level indicated on the system-wide rule curve*."

The above statement is an at empt to set new storage and outflow "rules". The agencies and stakeholder's principal interests are Ripogenus impoundment elevation and outflows. When included in a system wide plan without drawdown restrictions, the Ripogenus Impoundment will continuously be responsible for meeting Penobscot Mills Project elevation and flow requirements. High North Twin Dam peaking outflows become an excuse to drain the Ripogenus Impoundment.

The above statement also is contradictory and an excellent example of "wordsmithing". The Licensee claims they do not use a rule curve, rather they use something **called "the system-wide rule curve." Other than the Licensee has shifted its use of "storage conditions", I** fail to see the difference. The Storage impoundments (P-2634) have not changed. New environmental constraints imposed by the (P-2634) 2004 Setl ement, change operations only marginally with the addition of five additional storage ponds.

General Comments Appendix B:

It appears that the Operations Model is set to produce impoundment elevation suitable for generation and to minimize spills. Minimum flows are only included when mandated by License conditions. This results in a drawdown regime that at times can reach a point where 1100 cfs (or 1000 cfs) flow is "allowed" e.g., September 17 - October 18 and prior to the November spawning season.[2]

4.1 Potential Reference Basins - HDR Engineering, Inc (HDR*) "development of a reference hydrograph for the Operations Model began with a compilation of the available USGS gages in the vicinity of the area of interest. …. only two gages are located directly inside the Ripogenus-Penobscot watershed". These two gages are located in the northeastern corner of the Ripogenus-Penobscot watershed (Figure 4-1) and both are regulated."*
